National Building Code Sectional Committee, CED 46

FOREWORD

The Planning Commission, soon after the Third Five Year Plan, decided that the whole gamut of operations involved in construction, such as administrative, organizational, financial and technical aspects, be studied in depth. For this study, a Panel of Experts was appointed in 1965 by the Planning Commission and its recommendations are available in the 'Report on Economies in Construction Costs', published in 1968.

This study resulted in a recommendation that a National Building Code (NBC) be prepared to unify the building regulations throughout the country for use by government departments, municipal bodies and other construction agencies. The then Indian Standards Institution (now Bureau of Indian Standards) was entrusted by the Planning Commission with the responsibility of preparation of the National Building Code. Accordingly, Bureau of Indian Standard (then ISI) brought out first NBC in 1970. The same was subsequently revised in 1983, 2005 and 2016.

The third revision of NBC was published in 2016. This was a result of large scale changes in the building construction activities, such as change in nature of occupancies with prevalence of high rises and mixed occupancies, greater dependence and complicated nature of building services, development of new/innovative construction materials and technologies, greater need for preservation of environment and recognition of need for planned management of existing buildings and built environment, resulting in a paradigm shift in building construction scenario. A comprehensive revision was therefore brought out to address all these aspects and also reflect the changes incorporated in various standards which were considerably utilized in the 2016 revision.

Since the last revision, many things have changed, including per capita land availability, growing infrastructure requirements, socio-economic conditions, and technological advancements, to name a few. Hence, in these changing times, the requirements for development have also changed. The faster economic growth that India needs at present is possible if the ongoing reforms help the infrastructure sector to operate efficiently and compete cost-effectively by utilizing the available land optimally and reducing excessive compliance burden.

Based on the current realities, socio-economic scenario existing in the country, and the requirement of rapid urbanization and income growth, the total building stock is projected to increase exponentially in the coming years. Further, construction and infrastructure development are poised to determine the speed and scale of progress across every sector. These enable mobility, clean water, energy, and urban growth, which all directly contribute and shape economic opportunity and quality of life.

Construction, being a state subject, the contribution of the state government and local authorities are significant in infrastructure growth of the country. However, the land resources are limited. Maximum utilization of land resources is of prime importance in the current scenario. Further, India has come a long way from the time of first publication of the building code to the present day status. The requirements of standards and codes have also changed from a prescriptive regime, where the States and Local Authorities required hand holding, to now a more performance oriented outlook giving ample scope for innovation and decision making. The knowledge base in the country has also increased exponentially with exposure to the global best practices and adapting them to suit the country specific needs. Consequently, the contents of the current version, in which this publication has been renamed as the National Building Construction Standards (NBCS), have undergone substantial changes from those of the earlier NBC.

Thus in the current (fifth) version, this NBCS has been restructured substantially with a more safety and performance oriented approach rather than a prescriptive one. This includes leaving the adminstrative provisions land use requirements, like floor area ratio (FAR), development control rules (DCRs) and parking norms, which falls under the domain of local and state government, from the ambit of this NBCS. Open spaces, ground coverage, space utilization and land use related matters are primarily the state subject, and as such, these items have also not been included in this NBCS. As regards, other aspects covering construction practices, landscaping, sustainability aspects of built environment and asset and facility management, which are not directly linked to the design requirements vis-a-vis safety of the built environment have been taken out of this NBCS and will be published separately as guidelines of good practices mainly addressing management, sustainability, maintenance and practices to improve the working and efficiency of the built environment. The portions covering building materials, structural design aspects, building services and plumbing services are retained as part of this NBCS.

The fire and life safety aspect, a state subject, but due to its importance towards the safety and well-being of the occupants as well as the common public, has also been included in this NBCS.

The current version of this NBCS with the restructuring is as follows:

a) The current version consists of

Foreword

Part A	Introduction
Part B	Building Materials
Part C	Structural Design
Part D	Building Services
Part E	Plumbing Services
Part F	Fire and Life Safety

Index of Terms

b) The other Parts of NBC 2016, namely Part 7 'Construction Management, Practices and Safety'; Part 10 'Landscape Development, Signs and Outdoor Display Structures'; Part 11 'Approach to Sustainability'; and Part 12 'Asset and Facility Management', have also been taken out of this NBCS. However, these will be brought out separately as special publication in the form of handbooks of good practices.

Towards making this NBCS more comprehensive, forward-looking and easy to implement, various technical aspects have been introduced apart from updating the existing provisions. The key points that have been addressed in this version of NBCS are:

1) Innovative building materials.
2) Review of blast-resistant design of buildings.
3) Detailed review of ground improvement techniques and inclusion of combined piled-raft foundations.
4) Inclusion of design parameters of new and imported timber species.
5) Construction methodologies using various bamboo species.
6) Inclusion of earthquake resistant systems of masonry.
7) Inclusion of the structural safety aspect of tall concrete buildings.
8) Updating the provisions on structural steel based design; and inclusion of a new section on composite construction.
9) Detailed provisions on glazing systems covering therein bullet-resistant glass and blast-resistant glass.
10) Charging infrastructure for electric vehicles.
11) Inclusion of provisions relating to renewable energy sources for buildings, such as rooftop solar photovoltaic (PV) systems, building-integrated photovoltaic (BIPV) systems, and solar water heating systems.
12) Inclusion of new section on power-driven parking systems for vehicles in buildings.
13) Focus on water-efficient fixtures in buildings; bio-digesters and packaged sewage treatment plants or decentralized STPs.

Notwithstanding the above, the repeated onslaught of natural calamities such as earthquakes, cyclones, landslides, floods, faced by the country has brought home the ever-increasing need for a common guiding document to enable monitoring and implementation of sound technical provisions and comprehensive features built into such a document. This NBCS fulfills this need apart from bringing at one place comprehensive provisions relating to selection of building materials, resilient design principles, various building services and plumbing services, etc, all ensuring to follow a unified approach thereby promoting resource efficiency, environmental responsibility and long-term resilience. This NBCS also captures the global best practices and technological developments in setting a robust roadmap towards establishing a more efficient mechanism promoting ease of doing business.

As the regulation of land development and buildings is a State subject and is dealt by the States and local bodies such as urban (and rural) local bodies within their jurisdiction through building regulatory documents like building regulations, development control rules building byelaws, and fire regulations, this document is voluntary in nature and is non-binding. The implementation depends on adoption or adaptation by concerned parties or stipulations in a contract or by appropriate adoption by the concerned authorities.

NATIONAL BUILDING CONSTRUCTION STANDARDS

PART A INTRODUCTION

This Part covers guidelines to be followed for judicious implementation of the provisions of various Parts/Sections of the National Building Construction Standards (NBCS), following a systematic approach.

In order to provide safe and resilient habitat, careful consideration needs to be paid to the building construction activity. Building planning, designing and construction activities have developed over the centuries. Large number of ancient monuments and historical buildings all over the world bear testimony to the growth of civilization from the prehistoric era with the extensive use of manual labour and simple systems as appropriate to those ages to the present day mechanized and electronically controlled operations for designing and constructing buildings and for operating and maintaining systems and services. Technological and socio-economic developments in recent times have led to remarkable increase in demand for more and more sophistication in buildings resulting in ever increasing complexities. For achieving these performance demand high levels of inputs from professionals of different disciplines such as architecture, civil engineering, structural engineering, functional and life safety services including special aspects relating to utilities, landscaping in conceptualization, spatial planning, design and construction of buildings of various material and technology streams, and various services including operation, maintenance, repairs and rehabilitation aspects throughout the service life of the building.

Present day construction scenario enables freedom of action to adopt appropriate practices and provides for building planning, designing and construction for absorbing traditional practices as well as latest developments in knowledge in the various disciplines as relevant to a building including computer aided and/or other modern sensors aided activities in the various stages of conceptualization, planning, designing, constructing, maintaining and repairing the buildings. India being a large country with substantial variations from region to region, this document has endeavoured to meet the requirements of different regions of the country, both urban and rural, by taking into consideration factors such as climatic and environmental conditions, geographical terrain, vulnerability to natural disasters, ecologically appropriate practices, use of eco-friendly materials, use of appropriate conventional and alternative technologies, and also socio-economic considerations, towards the creation of sustainable human settlements and built environment.

Buildings can be classified based on occupancy and types of construction as below:

Occupancy classification

a) Residential;
b) Educational;
c) Institutional;
d) Assembly;
e) Business;
f) Mercantile;
g) Industrial;
h) Storage; and
j) Hazardous.

Types of construction — Based on fire resistance rating for different set of components (suitably covered under Part F — Fire and Life Safety) are:

i) Type 1;
ii) Type 2;
iii) Type 3; and
iv) Type 4.

Buildings have various parts (such as plinth, habitable rooms, kitchen, bathroom and water closets, ledges, mezzanine, store room, garage, basement, parapet, cabin, boundary wall, wells, septic tanks, meter rooms, staircases, roofs) and specific requirements such as essential habitable sizes/ heights, distance between well and septic tanks, to name a few that ensure a liveable environment thereby addressing health, safety and public safety. The safe distance between buildings and electric lines is also essential towards occupant safety. Accessibility for persons with disabilities and the elderlies in specific public buildings and low income housing are also essential towards inclusivity in the built spaces. Open spaces within a plot also play a crucial part for harnessing natural lighting and ventilation, apart from movement space for fire tenders/emergency vehicles. Commensurate vehicular parking facilities within a built environment are also important so as to not burden the public spaces like roads/right of way. Such aspects may vary from place to place be it in the plains, hills and coastal areas; for which the state/local authorities should specify the specific criteria.

Based on their complexity, buildings may be classified as high rise buildings or special buildings in which the number of inmates and the requirement for their safe and habitable living are to be addressed. Importantly, the constructed buildings need to be well maintained and periodically audited covering structural audit, electrical audit, fire audit, accessibility audit to be carried out over the useful life of a building, say every 3 to 5 years.

A building project and the built facility in each stage necessarily requires professionals of many disciplines who should work together as a well-coordinated team to achieve the desired product delivery with quality, safety and other objectives, in an effective manner.

In large/complex projects, appropriate multi-disciplinary teams may be constituted to successfully meet the requirements of different stages. These may be design team, project management/execution team and operation and maintenance teams. Each team may comprise need-based professionals out of the following depending upon the nature, magnitude and complexity of the project:

1) architect;

2) civil engineer;

3) structural engineer;

4) geotechnical engineer;

5) electrical engineer;

6) plumbing engineer;

7) fire protection engineer;

8) heating, ventilation and air conditioning engineer;

9) lift, escalator and moving walk specialist;

10) acoustics specialist;

11) information/communication technology engineer;

12) health, safety and environment specialist;

13) environment/sustainability specialist;

14) town planner;

15) urban designer;

16) landscape architect;

17) security system specialist;

18) interior designer;

19) quantity surveyor;

20) project/construction manager;

21) project planning and construction digitization specialist;

22) accessibility and universal design specialist; and

23) other subject specialist(s).

This NBCS (Part A) gives an overall direction for understanding the provisions of different types of buildings and built environment, and proposes guidance for utilizing appropriate knowledge and experience of qualified professionals, right from the conceptualization through construction and completion stages of a building project and indeed during the entire life cycle.

This part has been so formulated as to necessitate guidance to ensure quality and safety in the whole gamut of activities, primarily divided into planning, design and execution of a building or built environment. This may be ensured by obtaining assistance from the registered professionals involved in planning, design, execution, and supervision. Apart from these, various other resource groups are involved whose contribution may be duly taken into account depending on the type, nature, magnitude and complexity of the project, such as security system specialist, environment specialist/sustainability and green building specialist, accessibility specialist, project management consultant, interior designer in proper construction/erection, commissioning and operation of buildings and built environment. In this endeavour, a guide for qualification and competence of the associated professionals, is included in Annex A.

The aim of this Part is to get the maximum benefit from the building and its services in terms of objectives such as quality, timeliness and cost-effectiveness by following a team approach. In the team approach, which is an essential pre-requisite for a unified approach, the aim clearly is to maximize the efficiency of the total system through appropriate optimization of each of its sub-systems, and ensuring coordination among various disciplines and agencies that are involved during planning, design, construction, operation and maintenance of buildings and the associated infrastructure. In other words, in the team, the timely inputs from each of the professional disciplines have to be so optimized that the total system's efficiency becomes maximum. These teams may be design team, construction/execution team, and operation and maintenance team.

It is important that leaders and members of the teams, depending on the size and complexity of the project, are carefully selected considering their qualification, experience and expertise in these fields.

Tools like building information modelling (BIM) may be adopted in all major and complex building projects as they help in managing and sharing information throughout the life cycle of the project enabling better collaboration, planning and decision making. In such projects, BIM may be strategically adopted to enhance the multi-disciplinary approach in design and execution and as a fundamental tool in the planning and development stages.

After the useful service life of a building is over, or for other reasons such as redevelopment and proposed change in use of the land and built facility, it may be required to deconstruct a building. Such a deconstruction is preceded by an organized decommissioning. The decommissioning and deconstruction needs to be well planned and coordinated among concerned building professionals so as to ensure safety during such operations, as also retrieval of appropriate components and systems, for their possible reuse or recycling, or disposal as may be appropriate. This may in turn require a comprehensive decommissioning and deconstruction (including demolition) plan, which may be prepared during the initial stages of the project and kept available for use at the end of life cycle of the same.

ANNEX A

GUIDE FOR THE QUALIFICATIONS AND COMPETENCE OF REGISTERED BUILDING PROFESSIONALS

A-1 ESSENTIAL REQUIREMENTS

Every building/development work should be planned, designed and supervised by registered professionals. The registered professionals for carrying out the various activities should be: (a) architect, (b) engineer, (c) structural engineer, (d) geotechnical engineer, (e) supervisor, (f) town planner, (g) landscape architect, (h) urban designer, and (j) utility services engineer. Requirements of registration for various professionals by the Authority or by the body governing such profession and constituted under a statute, as applicable to practice within the local body's jurisdiction, are given in **A-2.1** to **A-2.8**. The competence of such registered personnel to carry out various activities is also indicated in **A-2.1.1** to **A-2.8.1**.

The qualification and competence of the engineers for utility services and of builder/constructor is prescribed in **A-2.9** and **A-2.10**, respectively. The qualification and competence of the professionals involved in peer reviewing/ proof checking with respect to structural design is prescribed in **A-2.11.**

A-2 REQUIREMENTS FOR REGISTRATION AND COMPETENCE OF BUILDING PROFESSIONALS

A-2.1 Architect

The minimum qualifications for an architect should be the qualifications as provided for in the *Architects Act*, 1972 for registration with the Council of Architecture.

A-2.1.1 *Competence*

The registered architect should be competent to carry out the work related to the building/development permit as given below:

a) Preparation of all plans and information connected with building permit except engineering services of high rise/special buildings;

b) Issuing certificate of supervision and completion of all buildings pertaining to architectural aspects;

c) Preparation of subdivision/layout plans and related information connected with development permit of area up to 1 ha for metro-cities, and 2 ha for other places; and

d) Issuing certificate of supervision for development of land of area up to 1 ha for metro-cities, and 2 ha for other places.

A-2.2 Engineer

The minimum qualifications for an engineer should be graduate in civil engineering/architectural engineering of recognized Indian or foreign university, or the Corporate Member of Civil Engineering Division/Architectural Engineering Division of the Institution of Engineers (India) or the member of the statutory body governing such profession, as and when established.

A-2.2.1 *Competence*

The registered engineer should be competent to carry out the work related to the building/development permit as given below:

a) Preparation of all plans and information connected with building permit;

b) Structural details and calculations of buildings including sub-surface investigation on plot up to 500 m^2 and up to 5 storeys or 16 m in height;

c) Issuing certificate of supervision and completion for all buildings;

d) Preparation of subdivision/layout plans and related information connected with development permit of area up to 1 ha for metro-cities, and 2 ha for other places;

e) Preparation of all service plans and related information connected with development permit; and

f) Issuing certificate of supervision for development of land for all area.

A-2.3 Structural Engineer

The minimum qualifications for a structural engineer should be graduate in civil engineering of recognized Indian or foreign university, or Corporate Member of Civil Engineering Division of Institution of Engineers (India), and with minimum 3 years' experience in structural engineering practice with designing and field work.

NOTE — The 3 years' experience may be relaxed to 2 years in the case of post graduate degree of recognized Indian or foreign university in the branch of structural engineering. In case of doctorate in structural engineering, the experience required would be one year.

A-2.3.1 *Competence*

The registered structural engineer should be competent to prepare the structural design, calculations and details for all buildings and carry out supervision.

A-2.3.1.1 In case of buildings having special structural features, as decided by the Authority, which are within the horizontal areas and vertical limits specified in **A-2.2.1**(b) and **A-2.5.1**(a) should be designed only by structural engineers.

A-2.4 Geotechnical Engineer

The minimum qualifications for a geotechnical engineer should be graduate in civil engineering of recognized Indian or foreign university, or Corporate Member of Civil Engineering Division of Institution of Engineers (India), and with minimum 3 years' experience in geotechnical engineering practice with designing and field work.

NOTE — The 3 years' experience may be relaxed to 2 years in the case of post graduate degree of recognized Indian or foreign university in the branch of geotechnical engineering. In case of doctorate in geotechnical engineering, the experience required would be one year.

A-2.4.1 *Competence*

The registered geotechnical engineer should be competent to carry out sub-surface investigations and give report thereof. These may *inter-alia* include performing various tests required to determine engineering properties of sub-strata and ground water and making recommendations about the type of foundation, soil bearing capacity and the depth at which the foundations shall be placed, considering the structural system and loads provided by the engineer/structural engineer.

A-2.4.1.1 In case of buildings to be founded on soils having special geotechnical conditions, as decided by the Authority, which are within the horizontal areas and vertical limits specified in **A-2.2.1**(b) and **A-2.5.1**(a) should be designed only by geotechnical engineers.

A-2.4.1.2 For specific information on pre-construction services and construction stage services to be provided by the geotechnical engineers, reference may be made to IS 19235 : 2025 'Geotechnical engineering services — Requirements'.

A-2.5 Supervisor

The minimum qualifications for a supervisor should be diploma in civil engineering or architectural assistantship, or the qualification in architecture or engineering equivalent to the minimum qualification prescribed for recruitment to non-gazetted service by the Government of India plus 5 years' experience in building design, construction and supervision.

A-2.5.1 *Competence*

The registered supervisor should be competent to carry out the work related to the building permit as given below:

a) All plans and related information connected with building permit for residential buildings on plot up to 200 m^2 and up to two storeys or 7.5 m in height; and

b) Issuing certificate of supervision for buildings as per (a).

A-2.6 Town Planner

The minimum qualification for a town planner should be the Associate Membership of the Institute of Town Planners or graduate or post-graduate degree in town and country planning.

A-2.6.1 *Competence*

The registered town planner should be competent to carry out the work related to the development permit as given below:

a) Preparation of plans for land subdivision/layout and related information connected with development permit for all areas; and

b) Issuing of certificate of supervision for development of land of all areas.

NOTE — However, for land layouts for development permit above 5 ha in area, landscape architect may also be associated, and for land development infrastructural services for roads, water supplies, sewerage/drainage, electrification, the registered engineers for utility services may be associated.

A-2.7 Landscape Architect

The minimum qualification for a landscape architect should be the bachelor master's degree in landscape architecture or equivalent from recognized Indian or foreign university.

A-2.7.1 *Competence*

The registered landscape architect should be competent to carry out the work related to landscape design for building/development permit for land areas 5 ha and above. In case of metro-cities, this limit of land area may be 2 ha and above.

NOTE — For smaller areas below the limits indicated above, association of landscape architect may also be considered from the point of view of desired landscape development.

A-2.8 Urban Designer

The minimum qualification for an urban designer should be the master's degree in urban design or equivalent from recognized Indian or foreign university.

A-2.8.1 *Competence*

The registered urban designer should be competent to carry out the work related to the building permit for urban design for land areas more than 5 ha and campus area more than 2 ha. He/she should also be competent to carry out the work of urban renewal for all areas.

NOTE — For smaller areas below the limits indicated above, association of urban designer may be considered from the point of view of desired urban design.

A-2.9 Engineers for Utility Services

The work of building and plumbing services should be executed under the planning, design and supervision of competent personnel. The qualification for registered mechanical engineer (including HVAC), electrical engineer and plumbing engineers for carrying out the work of air conditioning, heating and mechanical ventilation, electrical installations, lifts and escalators and water supply, drainage, sanitation and gas supply installations respectively should be as given in Part D 'Building Services' and Part E 'Plumbing Services' of this NBCS or as decided by taking into account practices of the national professional bodies dealing with the specialist engineering services.

Such an approach may be followed for association of other/multi-disciplinary professionals for taking inputs and associating with their areas of specialization. For example, specific to fire (as covered under Part F 'Fire and Life Safety' of this NBCS), the role of fire protection engineer is important, who could be, any of the following:

a) a graduate in fire protection engineering (or a related discipline like fire engineering, fire safety engineering, fire technology and safety engineering, of recognized Indian or foreign university);

b) a graduate in mechanical/civil/electrical/electronics engineering and having a post graduate degree in fire protection engineering;

c) a graduate in mechanical/civil/electrical/electronics engineering and having at least 10 years of experience in the field of planning, designing, and commissioning of fire protection work;

d) an advance diploma in fire engineering (Divisional Officers Course) from National Fire Service College, Nagpur and having atleast five years' experience in the field of fire prevention, fire protection and fire safety matters; and

e) a diploma in fire engineering from National Fire Service College, Nagpur and having atleast ten years' experience in the field of fire prevention, fire protection and fire safety matters.

NOTE — The existing fire protection professionals having graduation in science or diploma in engineering having experience of at least 10 years may be allowed for the activity.

A-2.10 BUILDER/CONSTRUCTOR

The minimum qualification for the builder/constructor or his representative for execution of respective works should be as given in **A-2.1**, **A-2.2**, **A-2.3**, **A-2.4**, **A-2.5**, **A-2.6**, **A-2.7**, **A-2.8** and **A-2.9** for the concerned professional.

A-2.10.1 Competence

The qualified builder/constructor or his representative should be competent to carry out execution of work, which should have the same extent as for supervision by such professional as prescribed in **A-2.1.1**, **A-2.2.1**, **A-2.3.1**, **A-2.4.1**, **A-2.5.1**, **A-2.6.1**, **A-2.7.1**, **A-2.8.1** and **A-2.9**.

A-2.11 PEER REVIEWER/PROOF CHECKER (FOR STRUCTURAL DESIGN)

The individual peer reviewer/proof checker or the team leader of the peer review/proof checking organization should have the following qualification, experience and competence:

a) *For buildings up to the height of 15 m*

B.E./B.Tech (Civil) with 7 years of experience in structural engineering practice with designing and field work of relevant structures. The 7 years of experience should comprise a minimum of 5 years exclusively in structural designing.

b) *For buildings of height more than 15 m and up to 50 m*

B.E./B.Tech (Civil) with 10 years of experience in structural engineering practice with designing and field work of relevant structures. The 10 years of experience should comprise a minimum of 7 years exclusively in structural designing.

c) *For buildings of height more than 50 m and specialized structures*

  1) Master's degree with major in structural engineering and 10 years of experience in structural engineering practice with designing and field work of relevant structures. The 10 years of experience should comprise a minimum of 7 years exclusively in structural designing; or

  2) B.E./B.Tech (Civil) with 15 years of experience in structural engineering practice with designing and field work of relevant structures. The 15 years of experience should comprise a minimum of 10 years exclusively in structural designing.

d) Peer review may also be carried out by reputed academic institutions/research institutions (such as IITs, NITs, IISc, leading engineering colleges, CSIR-SERC, CBRI, CRRI).

NATIONAL BUILDING CONSTRUCTION STANDARDS

LIST OF STANDARDS ... 8

National Building Code Sectional Committee, CED 46

FOREWORD

This NBCS (Part B) lists Indian Standard specifications for materials used in building construction. The Indian Standards for methods of tests, to ensure the requirements demanded of the materials in the various situations, are also included. This is with a view to ensuring the quality and effectiveness of building materials used in the construction and of their storage, which are as important as other aspects of building activity like planning, designing and constructing the building itself.

Historically, choice of building materials was determined by what was locally available, appropriateness to geo-climatic conditions and affordability of users. In the recent past, different initiatives have been taken in the areas of research and development, standardization, and development and promotion of innovative materials. A review of the recent trends indicates that the growth in the area of building materials covers emerging trends and latest developments in the use of wastes, mineral admixtures in cement and concrete, substitutes to conventional timber, composite materials and recycling of wastes, at the same time ensuring desired response of materials in relation to fire safety, long term performance and durability. In addition to these, nowadays, development of specific materials is being researched which may be structured and designed to meet needs to specially developed construction technologies in time to come, such as, for disaster prone areas or aggressive climatic and industrial situations.

To encourage use of appropriate materials, it may be desirable to have to the largest extent possible, performance oriented approach for specifications rather than prescriptive approach. The approach has been already adopted in some cases in development of standards, wherever found possible.

Indian Standards cover the requirements for most of the materials in use. However, there may be a gap between development of new materials and techniques of application and formulation of standards. It, therefore, becomes necessary for the NBCS to be flexible to recognize building materials other than those for which Indian Standards are available. This Part of NBCS, therefore, since its first version, duly takes care of this aspect and explicitly provides for use of new or alternate building materials, provided it is proved by authentic tests that the new or alternative material is effective and suitable for the purpose intended. However, it is worthwhile that more and more emphasis is given to the satisfaction of performance requirements expected of a building material, so that a wide range of such new or alternate materials can be evaluated and used, if found appropriate.

As already emphasized, quality of material is quite important for their appropriate usage, whether it is a material for which an Indian Standard is available or a new or alternative material as defined in **4** of this Part of the NBCS. While continuing to emphasize on conformity of building materials to available Indian Standards, this Part recommends that the building regulating authority may also recognize the use of building materials conforming to other specifications and test methods (*see* **4.2**), in case Indian Standards are not available for particular materials. Third party certification schemes available in the country for quality assurance of above materials can be used with advantage to ensure the appropriateness of these materials.

It is well recognized that buildings during their construction and subsequently in their operation consume lot of resources. The holistic approach for ensuring proper and sustainable developments is to take care of the concerned aspects affecting sustainability during the conceptualization, planning, design, construction, and operation and maintenance stages. The building material production, transportation and utilization assume a substantial component of the embodied energy that goes into a building. It is therefore important that sustainability of building materials is well understood and ensured in a building project. This Part of the NBCS recognizes this aspect and covers appropriate provision therefore.

This Part of the Code was first published in 1970 as part of the National Building Code of India and subsequently revised in 1983, 2005 and 2016 as Part 5 of NBC 2016. The first and second revision of this Part incorporated an updated version of the list of Indian Standards given at the end of this Part of the Code. Also the list of building materials was completely revised to make it more user-friendly. The third revision of this Part included a new clause on sustainable building materials, expanded the clause on new/alternative materials to provide examples of some potential new/alternative materials, reorganized some of the existing categories and added new categories either under the existing principal categories or as separate principal categories. Additionally, the list of Indian Standards was updated.

In this revision, this publication has been renamed as National Building Construction Standards (NBCS).

This fourth revision of this Part, while basically retaining the structure of previous version, incorporates the following modifications:

a) The clause on new/alternative materials has been updated with examples of some potential new/alternative materials;

b) A clause on recycled materials has been added to address/encourage the usage of recycled materials in building construction; and

c) The list at the end of this Part has been updated to reflect the latest available Indian Standard specifications and methods of test.

A reference to SP 21 : 2005 ‘Summaries of Indian Standards for Building Materials’ may be useful. This publication gives the summaries of Indian Standards covering various building materials, fittings and components except standards relating to paints.

All standards cross-referred in the main text of this Part, are subject to revision. The parties to agreement based on this Part are encouraged to investigate the possibility of applying the most recent editions of the standards.

As the regulation of land development and buildings is a State subject and is dealt by the States and local bodies such as urban local bodies within their jurisdiction through building regulatory documents like building regulations, building byelaws, and fire regulations, this document is voluntary in nature and is non-binding. The implementation depends on adoption by concerned parties or stipulations in a contract or by appropriate adoption by the concerned authorities.

For the purpose of deciding whether a particular requirement of this Part is complied with, the final value, observed or calculated, expressing the result of a test or analysis, shall be rounded off in accordance with IS 2 : 2022 ‘Rules for rounding off numerical values (*second revision*)’. The number of significant places retained in the rounded off value should be the same as that of the specified value in this Part.

NATIONAL BUILDING CONSTRUCTION STANDARDS

PART B BUILDING MATERIALS

1 SCOPE

This NBCS (Part B) covers the requirements of building materials and components, and criteria for accepting new or alternative building materials and components.

2 MATERIALS

Every material used in fulfilment of the requirements of this Part, unless otherwise specified in this NBCS or approved, shall conform to the relevant Indian Standards. A list of Indian Standard specifications as the 'accepted standards' is given at the end of this Part of the NBCS. At the time of publication of this NBCS, the editions indicated were valid. All standards are subject to amendments and revisions. The Authority shall take cognizance of such amendments and revisions. The latest version of a specification shall, as far as possible, be adopted at the time of enforcement of this Part of the NBCS.

3 SUSTAINABLE MATERIALS

Choice of building materials is important in sustainable design because of the extensive network of activities such as extraction, processing and transportation steps required for making a material, and activities involved thereafter till building construction and even thereafter. These activities may pollute the air, soil and water, as well as destroy natural habitats and deplete natural resources. One of the most effective strategies for minimizing the environmental impacts of material usage is to reuse existing buildings. Rehabilitation of existing building, and their shell and non-shell components, not only reduces the volume of solid waste generated and its subsequent diversion to landfills but also the environmental impacts associated with the production, delivery and use or installation of new building materials. However, the use of sustainable building materials is one of the best strategies in the pursuit to sustainable buildings.

An ideal sustainable building material is not only environment friendly but also causes no adverse impact on health of occupants, is readily available, can be reclaimed and recycled, and is not only made from renewable raw material, but also uses predominantly renewable energy in its extraction, production, transportation, fixing and ultimate disposal. Practically, this kind of ideal material may not be available and hence, it may be best to choose materials which fulfil most of these criteria. Sustainable building materials also offer specific benefits to the building owner and building occupants, such as, reduced maintenance/replacement costs over the life of the building; energy conservation; improved occupant health and productivity; lower costs associated with changing space configurations; and greater design flexibility.

The use of used materials (*see* **6**) and recycled and waste materials (*see* **7**) contribute substantially towards sustainability of building material usage.

The selection of sustainable building materials may be made in accordance with relevant guidelines/best practices (Handbook on 'Sustainability in Buildings').

4 NEW OR ALTERNATIVE MATERIALS

4.1 The provisions of this Part are not intended to prevent the use of any material not specifically prescribed under **2**. Any such material may be approved by the Authority or an agency appointed by them for the purpose, provided it is established that the material is satisfactory for the purpose intended and the equivalent of that required in this Part or any other specification issued or approved by the Authority. The Authority or an agency appointed by them shall take into account the following parameters, as applicable to the concerned new or alternative building material:

a) Requirements of the material specified/expected in terms of the provisions given in the standards on its usage, including its applicability in geo-climatic condition;

b) General appearance;

c) Dimension and dimensional stability;

d) Structural stability including strength properties;

e) Fire safety;

f) Durability;

g) Thermal properties;

h) Mechanical properties;

j) Acoustical properties;

k) Optical properties;

m) Biological effect;

n) Environmental aspects;

p) Working characteristics;

q) Ease of handling;

r) Consistency and workability;

s) UV resistance; and

t) Toxicity.

Some of such new/alternative materials may be decorative concrete, polymer concrete, plastic waste bricks, recycled plastic lumber, micro-concrete repair materials, dry-mix mortar, non-shrink grout, special materials for bunkers/blast resistant structures, artificial stones, nanotechnology based advanced materials, vermiculite based boards, exfoliated perlite, pervious concrete, high-pressure laminate sheet, aluminium honeycomb panels, zinc composite panels, stainless steel insulated water tanks, etc.

For establishing the performance of the material/component, laboratory/field tests, and field trials, as required, and study of historical data are recommended. For sampling and frequency of tests for new or alternate materials, similar product standards shall be referred to.

The above materials would no longer be treated as new/alternative materials as soon as Indian Standards for the same are established.

4.2 Approval in writing of the Authority or an agent appointed by them for the purpose of approval of material, shall be obtained by the owner or his agent before any new, alternative or equivalent material is used. The Authority or their agent shall base such approval on the principle set forth in **4.1** and shall require that tests be made (*see* **9.1**) or sufficient evidence or proof be submitted, at the expense of the owner or his agent, to substantiate any claim for the proposed material.

5 THIRD PARTY CERTIFICATION

For ensuring the conformity of materials for which Indian Standards exist and for new or alternative building materials, to requisite quality parameters the services under the third party certification schemes of the Government, may be utilized with advantage.

6 USED MATERIALS

Utilization of used materials and recycled materials may not be precluded provided these meet the requirements of this Part for new materials.

7 RECYCLED MATERIALS AND WASTE MATERIALS

7.1 A recycled building material refers to any product or material that has been previously utilized in another construction context. Various materials, such as brick, steel, timber, and even entire components like doors, windows and tiles, can be reused and repurposed. This term also encompasses building materials produced from waste, such as recycled plastic bricks, or concrete made from recycled aggregate from buildings, structures and pavements. Using suitable technological interventions, the natural and industrial by-products/ wastes can be gainfully utilized in the construction activity, not merely as fillers, but in combination with traditional materials or through repurposing. Some such potential materials include: fly ash, bottom ash, red mud, flue gas desulfurization (FGD) gypsum, phosphogypsum, fluorogypsum, blast furnace slag, Linz-Donawitz (LD) slag, textile sludge, marble waste (from cutting and processing), granite waste (from cutting and processing), iron tailings, mine tailings, copper tailings, copper slag, coal mining waste (coal tailings), rice husk ash, jarosite, broken glass and ceramics, kiln dust, galvanizing waste, tannery waste, stone waste (from crusher units), metal plating industry sludge, lime sludge, vermiculite, perlite and bagasse and other agro-wastes. One of such recycled/waste derived materials is aggregate derived from construction and demolition (C&D) waste, as described in **7.1.1** and **7.1.2**.

7.1.1 *Recycled Mixed Aggregate and Recycled Concrete Aggregate*

Recycled mixed aggregate (RMA) is made from construction and demolition (C&D) waste which may comprise concrete, brick, tiles, stones, etc. C&D waste is generated from construction, renovation, repair, and demolition of buildings and other structures. Recycled concrete aggregate (RCA) on the other hand is derived from concrete waste after requisite processing. Recycled concrete aggregate (RCA) comprises not only the original aggregate, but also the hydrated cement paste adhering to its surface.

7.1.2 *Reclaimed Asphalt Pavement Aggregates*

Milling or demolition of distressed bituminous/flexible pavements generates reclaimed asphalt pavement (RAP) aggregates. These aggregates consist of natural stones fully coated with 2 percent to 7.5 percent (by mass) of bitumen/asphalt binder and are typically used in the construction of new bituminous roads. The use of RAP in cement concrete pavements is rather a new approach and has been found to enhance the workability and toughness characteristics. The strength properties should also be evaluated before permitting for use. Suitably, the coarser fraction of RAP can be used as part replacement (in the order of 10 percent to 20 percent) of natural aggregates for non-structural lean-concrete applications such as paver blocks, kerb stones, etc.

8 STORAGE OF MATERIALS

All building materials shall be stored on the building site in such a way as to prevent deterioration or the loss or impairment of their structural and other essential properties [see relevant guidelines/best practices (Handbook on 'Construction Management, Practices and Safety in Buildings')].

9 METHODS OF TEST

9.1 Every test of material as required in this Part or by the Authority shall be carried out in accordance with the methods of test prescribed in relevant Indian Standards. In cases of methods of tests for which Indian Standards are not available, the same shall conform to the methods of tests issued by the Authority or their agent. A list of Indian Standard methods of test is given at the end of this Part of the NBCS as the 'accepted standards'. Laboratory tests shall be conducted by recognized laboratories acceptable to the Authority.

9.1.1 The manufacturer/supplier shall satisfy himself that materials conform to the requirements of the specifications and if requested shall supply a certificate to this effect to the purchaser or his representative. When such test certificates are not available, the specimen of the material shall be tested.

LIST OF STANDARDS

Following are the Indian Standards for various building materials and components, to be complied with in fulfilment of the requirements of this NBCS.

In the following list, while enlisting the Indian Standards, the materials have been categorized in such a way as to make the list user friendly. In the process, if so required, some of the standards have been included even in more than one category of products, such as in the category based on composition as well as on end application of the materials. The list has been arranged in alphabetical order of their principal category as given below:

1. Aluminium and other light metals and their alloys
2. Bitumen and tar products
3. Bricks, blocks and other masonry building units
4. Builder’s hardware
5. Building chemicals
6. Building lime and products
7. Clay and stabilized soil products
8. Cement and concrete (including steel reinforcement for concrete)
9. Composite matrix products (including cement and resin matrix products)
10. Conductors and cables
11. Doors, windows and ventilators
12. Electrical wiring, fittings and accessories
13. Fillers, stoppers and putties
14. Floor covering, roofing and other finishes
15. Glass
16. Gypsum based materials
17. Mortar (including sand for mortar)
18. Paints and allied products
19. Polymers, plastics and geosynthetics/geotextiles
20. Sanitary appliances and water fittings
21. Steel and its alloys
22. Stones
23. Structural sections
24. Thermal insulation materials
25. Threaded fasteners, rivets and nails
26. Timber, bamboo and other lignocellulosic building materials
27. Unit weights of building materials
28. Waterproofing and damp-proofing materials
29. Welding electrodes and wires
30. Wire ropes and wire products (including wire for fencing)

(Part 4) : 2020	Tables of hardness values (*fifth revision*)
IS 1586	Metallic materials — Rockwell hardness test:
(Part 1) : 2025/ ISO 6508-1 : 2023	Test method (*sixth revision*)
(Part 2) : 2025/ ISO 6508-2 : 2023	Verification and calibration of testing machines and indenters (*sixth revision*)

IS No.	*Title*
IS 1586 (Part 3) : 2025/ ISO 6508-3 : 2023	Metallic materials — Rockwell hardness test: Part 3 Calibration of reference blocks (*sixth revision*)
IS 1716 : 2023	Metallic materials wire reverse bend test (*third revision*)
IS 1717 : 2018	Metallic materials — Wire — Simple torsion test (*fourth revision*)
IS 1757	Metallic materials — Charpy pendulum impact test:
(Part 1) : 2020	Test method (*fourth revision*)
(Part 2) : 2020	Verification of testing machines (*fourth revision*)
(Part 3) : 2020	Preparation and characterization of charpy V-notch test pieces for indirect verification of pendulum impact machines (*fourth revision*)
IS 1772 : 2024	Electroplated coatings of copper — Specification (*second revision*)
IS 1828 (Part 1) : 2022	Metallic materials — Calibration and verification of static uniaxial testing machines: Part 1 Tension/Compression testing machines — Calibration and verification of the force-measuring system (*fifth revision*)
IS 2258 : 2023	Rolled zinc plate, sheet and strip — Specification (*third revision*)
IS 2328 : 2018	Metallic materials — Tube — Flattening test (*third revision*)
IS 2479 : 1981	Colour code for the identification of aluminium and aluminium alloys for general engineering purposes (*second revision*)
IS 2605 : 2023	Zinc anodes for electroplating — Specification (*second revision*)
IS 2676 : 1981	Dimensions for wrought aluminium and aluminium alloys, sheet and strip (*first revision*)
IS 2677 : 1979	Dimensions for wrought aluminium and aluminium alloys, plates and hot rolled sheets (*first revision*)
IS 2782 : 2023	Refined nickel — Specification (*first revision*)
IS 3577 : 1992	Wrought aluminium and its alloys — Rivet, bolt and screw stock — Dimensions and tolerances (*first revision*)
IS 3711 : 2020	Steel and steel products — Location and preparation of samples and test pieces for mechanical testing (*third revision*)
IS 3965 : 1981	Dimensions for wrought aluminium and aluminium alloys bar, rod and section (*first revision*)
IS 4258 : 2018	Metallic materials — Conversion of hardness values (*third revision*)
IS 5075 : 2023	Metallic materials — Rotating bar bending fatigue testing (*second revision*)
IS 5528 : 2024/ ISO 9227 : 2022	Corrosion tests in artificial atmospheres — Salt spray tests (*second revision*)
IS 6477 : 1983	Dimensions for wrought aluminium and aluminium alloys extruded hollow sections (*first revision*)

IS No.	*Title*
IS 6885	Metallic materials — Knoop hardness test:
(Part 1) : 2025/ ISO 4545-1 : 2023	Test method (*third revision*)
(Part 2) : 2020	Verification and calibration of testing machines (*second revision*)
(Part 3) : 2020	Calibration of reference blocks (*second revision*)
(Part 4) : 2020	Tables of hardness values (*second revision*)
IS 7811 : 2019	Phosphor bronze rods and bars (*second revision*)
IS 8632 : 2023	Metallic materials — Designation of test specimen axes in relation to product texture (*first revision*)
IS 10175 : 2018	Metallic materials — Sheet and strip — Erichsen cupping test (*third revision*)
IS 11999 : 2022	Metallic materials — Sheet and strip — Determination of plastic strain ratio (*second revision*)
IS 12260 : 2018	Metallic materials — Tube — Ring —Expanding test (*first revision*)
IS 12278 : 2018	Metallic materials — Tube — Ring tensile test (*second revision*)
IS 12444 : 2020	Copper wire rods for electrical applications — Specification (*first revision*)
IS 12871 : 2022	Copper, lead, zinc and nickel concentrates — Sampling procedures for determination of metal and moisture content (*second revision*)
IS 14712 : 2025	Wrought aluminium and its alloys — Chequered/tread sheets for general engineering purposes — Specification (*first revision*)
IS 15756 : 2022	Metallic materials — Sheet and strip — Determination of tensile strain hardening exponent (*first revision*)
IS 15965 : 2012	Pre-painted aluminium zinc alloy metallic coated steel strip and sheet (Plain)
IS 16842 : 2022	Metallic materials — Fatigue testing — Fatigue crack growth method (*first revision*)
IS 16843 : 2018	Metallic materials — Fatigue testing — Strain-controlled thermomechanical fatigue testing method
IS 17143 : 2023	Metallic materials torque — Controlled fatigue testing (*first revision*)
IS 17144	Metallic materials — Instrumented indentation test for hardness and materials parameters:
(Part 1) : 2019	Test method
(Part 2) : 2019	Verification and calibration of testing machines
(Part 3) : 2019	Calibration of reference blocks
(Part 4) : 2019	Test method for metallic and non-metallic coatings

IS No.	*Title*
IS 17145	Metallic materials — Fatigue testing — Variable amplitude fatigue testing:
(Part 1) : 2019	General principles, test method and reporting requirements
(Part 2) : 2019	Cycle counting and related data reduction methods
IS 17149	Metallic materials — Leeb hardness test:
(Part 1) : 2019	Test method
(Part 2) : 2019	Verification and calibration of the testing devices
(Part 3) : 2019	Calibration of reference test blocks
IS 17151 : 2023	Metallic materials unified method of test for the determination of quasistatic fracture toughness (*first revision*)
IS 17413	Metallic materials — Tensile testing at high strain rates:
(Part 1) : 2020	Elastic-bar-type systems
(Part 2) : 2020	Servo-hydraulic and other systems
IS 17415 : 2023	Metallic materials torsion test at room temperature (*first revision*)
IS 17416 : 2024/ ISO 14556 : 2023	Metallic materials — Charpy V-Notch pendulum impact test — Instrumented test method (*first revision*)
IS 17418 : 2020	Metallic materials — Sheet and strip — Biaxial tensile testing method using a cruciform test piece
IS 17146 (Part 1) : 2023	Metallic materials determination of forming-limit curves for sheet and strip: Part 1 Measurement and application of forming-limit diagrams in the press shop (*first revision*)
IS 17417	Metallic materials — Dynamic force calibration for uniaxial fatigue testing:
(Part 1) : 2020	Testing systems
(Part 2) : 2020	Dynamic calibration device (DCD) instrumentation
IS 17419 : 2025	Metallic materials — Ductility testing — High speed compression test for porous and cellular metals (*first revision*)
IS 17679 : 2021	Metallic materials — Method of test for the determination of quasistatic fracture toughness of welds
IS 17682 : 2021	Aluminium composite panel specification
IS 17795 : 2025	Metallic materials — Uniaxial creep testing in tension — Method of test (*first revision*)
IS 17915 : 2022	Method for evaluation of tensile properties of metallic superplastic materials
IS 17937 : 2022	Mechanical testing of metals ductility testing compression test for porous and cellular metals
IS 18649 : 2024/	Corrosion of metals and alloys — Alternate immersion test in salt solution

IS No.	*Title*
ISO 11130 : 2017	
IS 18650 : 2024/ ISO 26146 : 2012	Corrosion of metals and alloys — Method for metallographic examination of samples after exposure to high-temperature corrosive environments

2 BITUMEN AND TAR PRODUCTS

IS No.	*Title*
IS 73 : 2013	Paving bitumen — Specification (*fourth revision*)
IS 212 : 2021	Crude coal tar for general use (*third revision*)
IS 216 : 2006	Coal tar pitch — Specification (*second revision*)
IS 217 : 2018	Cutback bitumen — Specification (*third revision*)
IS 218 : 1983	Specification for creosote oil for use as wood preservatives (*second revision*)
IS 334 : 2023	Glossary of terms relating to bitumen and tar (*fourth revision*)
IS 702 : 2022	Specification for industrial bitumen (*third revision*)
IS 1201 to IS 1220	Methods for testing tar and bituminous materials:
IS 1201 : 2021	Sampling (*second revision*)
IS 1202 : 2021	Determination of specific gravity (*second revision*)
IS 1203 : 2022	Determination of penetration (*second revision*)
IS 1204 : 2022	Determination of residue of specified penetration (*second revision*)
IS 1205 : 2022	Determination of softening point — Ring and ball apparatus (*second revision*)
IS 1206	Determination of viscosity:
(Part 1) : 2023	By volumetric flow rate method
(Part 2) : 2022	Absolute viscosity
(Part 3) : 2021	Kinematic viscosity
IS 1207 : 2022	Determination of equiviscous temperature EVT (*second revision*)
IS 1208	Methods for Testing Tar and Bituminous Materials
(Part 1) : 2023	Determination of ductility (*second revision*)
(Part 2) : 2023	Determination of elastic recovery (*second revision*)
IS 1209 : 2021	Determination of flash point and fire point (*second revision*)
IS 1210 : 2020	Float test (*second revision*)
IS 1211 : 2022	Determination of water content dean and stark method (*second revision*)
IS 1212 : 2022	Determination of loss on heating (*second revision*)

IS No.	*Title*
IS 1213 : 2025	Tar and bituminous materials — Distillation test — Methods of test (*third revision*)
IS 1215 : 2021	Determination of matter insoluble in toluene (*second revision*)
IS 1216 : 2023	Determination of solubility in trichloroethylene (*second revision*)
IS 1217 : 2024	Tar and bituminous materials — Determination of mineral matter (ash) — Methods of test (*second revision*)
IS 1218 : 2024	Tar and bituminous materials — Methods for test — Determination of phenols (*second revision*)
IS 1219 : 2024	Tar and bituminous materials — Methods for test — Determination of naphthalene (*second revision*)
IS 1220 : 2024	Tar and bituminous materials — Methods for test — Determination of volatile matter content *(second revision)*
IS 3117 : 2004	Bitumen emulsion for roads and allied applications (anionic type) — Specification (*first revision*)
IS 8887 : 2018	Bitumen emulsion for roads cationic type — Specification *(third revision)*
IS 9381 : 2024	Tar and bituminous materials — Determination of Fraass breaking point of bitumen — Methods of test (*first revision*)
IS 9382 : 2022	Methods for testing tar and bituminous materials — Determination of effect of heat and air by thin film oven test (*first revision*)
IS 10511 : 2024	Method for determination of asphaltenes in bitumen by precipitation with normal heptane (*first revision*)
IS 10512 : 2003	Method for determination of wax content in bitumen (*first revision*)
IS 13758	Coal tar pitch — Methods of test:
(Part 1) : 1993	Determination of matter insoluble in quinoline
(Part 2) : 1993	Determination of coking value
IS 14982 : 2022	Anti-Stripping agents for bitumen addition — Specification (*second revision*)
IS 15172 : 2002	Methods for testing tar and bituminous materials — Determination of curing index for cutback bitumens
IS 15173 : 2002	Methods for testing tar and bituminous materials — Determination of breaking point for cationic bitumen emulsion
IS 15174 : 2002	Methods for testing tar and bituminous material — Determination of breaking point for anionic bitumen emulsion
IS 15462 : 2019	Polymer modified bitumen (PMB) specification (*first revision*)
IS 15799 : 2021	Methods for testing tar and bituminous materials — Ageing of bitumen (RTFOT and PAV) (*first revision*)
IS 15808 : 2008	Multigrade bitumen for use in pavement construction — Specification
IS 17016 : 2018	Cationic modified bitumen emulsion — Specification

IS No.	*Title*
IS 17052 : 2018	Rejuvenating agents for hot mix recycling of bituminous surfacing — Specification
IS 17079 : 2019	Rubber modified bitumen (RMB) — Specification
IS 17116 : 2019	Determination of resistance of compacted bituminous mixture to moisture — Induced damage
IS 17124 : 2019	Crack sealants — Specification
IS 17127 : 2019	Determination of stability, flow and bulk density of bituminous mixes by Marshall method
IS 17335 : 2020	Determination of apparent viscosity of bituminous binders at elevated temperature by rotational viscometer
IS 18104 : 2022	Methods for testing tar and bituminous materials — Determination of draindown characteristics of uncompacted bitumen mixtures
IS 18130 : 2023	Method for recovery of bitumen from solution using rotary evaporator
IS 18883 : 2025	Trackless emulsion — Specification
IS 19008 : 2023	Determination of bitumen content in bituminous paving mixtures

3 BRICKS, BLOCKS AND OTHER MASONRY BUILDING UNITS

IS No.	*Title*
IS 1077 : 2025	Common burnt clay building bricks — Specification (*sixth revision*)
IS 1725 : 2023	Stabilized soil blocks used in general building construction — Specification (*third revision*)
IS 2180 : 1988	Specification for heavy duty burnt clay building bricks (*third revision*)
IS 2185	Specification for concrete masonry units:
(Part 1) : 2005	Hollow and solid concrete blocks (*third revision*)
(Part 2) : 1983	Hollow and solid lightweight concrete blocks (*first revision*)
(Part 3) : 1984	Autoclaved cellular (aerated) concrete blocks (*first revision*)
(Part 4) : 2008	Preformed foam cellular concrete blocks
IS 2222 : 1991	Specification for burnt clay perforated building bricks (*third revision*)
IS 2691 : 2017	Burnt clay facing bricks — Specification (*third revision*)
IS 2849 : 1983	Specification for non-load bearing gypsum partition blocks (solid and hollow types) (*first revision*)
IS 3115 : 1992	Specification for lime based blocks (*second revision*)
IS 3316 : 1974	Specification for structural granite (*first revision*)
IS 3495	Burnt clay building bricks method of tests:

IS No.	*Title*
(Part 1) : 2019	Determination of compressive strength (*fourth revision*)
(Part 2) : 2019	Determination of water absorption (*fourth revision*)
(Part 3) : 2019	Determination of efflorescence (*fourth revision*)
(Part 4) : 2019	Determination of warpage (*fourth revision*)
(Part 5) : 2021	Determination of initial rate of absorption
(Part 6) : 2022	Determination of modulus of rupture
IS 3583 : 1988	Specification for burnt clay paving bricks (*second revision*)
IS 3620 : 1979	Specification for laterite stone block for masonry (*first revision*)
IS 3952 : 2013	Burnt clay hollow bricks and blocks for walls and partitions — Specification (*third revision*)
IS 4139 : 1989	Specification for calcium silicate bricks (*second revision*)
IS 4860 : 1968	Specification for acid resistant bricks
IS 4885 : 1988	Specification for sewer bricks (*first revision*)
IS 5454 : 2024	Burnt clay bricks and burnt clay tiles — Methods of sampling (*second revision*)
IS 5751 : 1984	Specification for precast concrete coping blocks (*first revision*)
IS 5779 : 1986	Specification for burnt clay soling bricks (*first revision*)
IS 6165 : 1992	Dimensions for special shapes of clay bricks (*first revision*)
IS 9893 : 1981	Specification for precast concrete blocks for lintels and sills
IS 10360 : 1982	Specification for lime pozzolana concrete blocks for paving
IS 12440 : 1988	Specification for precast concrete stone masonry blocks
IS 12894 : 2002	Specification for pulverized fuel ash lime bricks (*first revision*)
IS 13757 : 1993	Burnt clay fly ash building bricks — Specification
IS 15658 : 2021	Concrete paving blocks — Specification (*first revision*)
IS 16720 : 2018	Pulverized fuel ash-cement bricks — Specification
IS 17165 : 2020	Manufacture of stabilized soil blocks — Guidelines

4 BUILDER’S HARDWARE

IS No.	*Title*
IS 204	Specification for tower bolts:
(Part 1) : 1991	Ferrous metals (*fifth revision*)
(Part 2) : 1992	Non-ferrous metals (*fifth revision*)

IS No.	*Title*
IS 205 : 1992	Specification for non-ferrous metal butt hinges (*fourth revision*)
IS 206 : 2010	Specification for tee and strap hinges (*fifth revision*)
IS 208 : 2020	Door handles — Specification (*sixth revision*)
IS 281 : 2009	Specification for mild steel sliding door bolts for use with padlocks (*fourth revision*)
IS 362 : 1991	Specification for parliament hinges (*fifth revision*)
IS 363 : 1993	Specification for hasps and staples (*fourth revision*)
IS 364 : 1993	Specification for fanlight catch (*third revision*)
IS 452 : 1973	Specification for door springs, rat-tail type (*second revision*)
IS 453 : 1993	Specification for double-acting spring hinges (*third revision*)
IS 729 : 2021	Drawer locks cupboard locks and box locks — Specification (*fourth revision*)
IS 1019 : 1974	Specification for rim latches (*second revision*)
IS 1341 : 2018	Steel butt hinges — Specification (*sixth revision*)
IS 1823 : 1980	Specification for floor door stoppers (*third revision*)
IS 1837 : 1966	Specification for fanlight pivots (*first revision*)
IS 2681 : 1993	Specification for nonferrous metal sliding door bolts for use with padlocks (*third revision*)
IS 3564 : 2025	Hydraulically regulated door closers — Specification (*fifth revision*)
IS 3818 : 1992	Specification for continuous (piano) hinges (*third revision*)
IS 3828 : 1966	Specification for ventilator chains
IS 3843 : 1995	Steel back flap hinges — Specification (*second revision*)
IS 4621 : 1975	Specification for indicating bolts for use in public baths and lavatories (*first revision*)
IS 4948 : 2020	Welded steel wire fabric for general use — Specification (*third revision*)
IS 4992 : 2024	Door handles for mortice locks — Specification (*second revision*)
IS 5187 : 1972	Specification for flush bolts (*first revision*)
IS 5899 : 1970	Specification for bathroom latches
IS 6315 : 2025	Hydraulically regulated floor springs — Specification (*third revision*)
IS 6318 : 1971	Specification for plastic window stays and fasteners
IS 6343 : 1982	Specification for door closers (pneumatically regulated) for light door weighing up to 40 kg (*first revision*)
IS 7196 : 1974	Specification for hold fast

IS No.	*Title*
IS 7197 : 1974	Specification for double action floor springs (without oil check) for heavy doors
IS 7534 : 1985	Specification for sliding locking bolts for use with padlocks (*first revision*)
IS 7881	Glossary of terms relating to builders' hardware:
(Part 1) : 2023	Locks (*first revision*)
(Part 2) : 2022	Latches (*first revision*)
IS 8756 : 1978	Specification for ball catches for use in wooden almirah
IS 9106 : 1979	Specification for rising butt hinges
IS 9131 : 2021	Rim locks and latches mechanically operated — Specification (*first revision*)
IS 9460 : 1980	Specification for flush drop handle for drawer
IS 9899 : 1981	Specification for hat coat and wardrobe hooks
IS 10019 : 1981	Specification for mild steel stays and fasteners
IS 10090 : 1982	Specification for numericals
IS 10342 : 1982	Specification for curtain rail system
IS 12817 : 2020	Stainless steel butt hinges — Specification (*third revision*)
IS 12867 : 1989	Specification for PVC hand rails covers
IS 14912 : 2001	Specification for door closers concealed type (hydraulically regulated)
IS 15833 : 2009	Stainless steel tower bolts — Specification
IS 15834 : 2020	Stainless steel sliding door bolts (Aldrops) for use with padlocks — Specification *(first revision)*
IS 16015 : 2022	Mortise locks and latches mechanically operated — Specification (*first revision*)
IS 16016 : 2013	Cylindrical locks with pin tumbler mechanism — Specification
IS 17296 : 2020	Stainless steel door stoppers — Specification
IS 17706 : 2022	Pull handles — Specification
IS 17954 : 2023	Telescopic ball bearing drawer slide — Specification
IS 18297 : 2023	Cabinet hinges — Specification

5 BUILDING CHEMICALS:

a) Anti-termite Chemicals

IS No.	*Title*
IS 5549 : 2023	Warfarin bait concentrates — Specification (*first revision*)
IS 7168 : 2023	Warfarin sodium salt water soluble powders — Specification (*first revision*)

IS No.	*Title*
IS 8703 : 2023	Diuron water dispersible powder concentrates — Specification (*first revision*)
IS 8944 : 2005	Chlorpyrifos emulsifiable concentrates — Specification (*first revision*)
IS 16706 : 2018	Carpropamid, technical — Specification
IS 16955 : 2019	Spiromesifen, suspension concentrate (SC) — Specification

b) Chemical Admixture/Water Proofing Compounds

IS No.	*Title*
IS 2645 : 2003	Integral waterproofing compounds for cement mortar and concrete — Specification (*second revision*)
IS 6925 : 1973	Methods of test for determination of water soluble chlorides in concrete admixtures
IS 9103 : 1999	Specification for concrete admixtures (*first revision*)

c) Sealants/Fillers

IS No.	*Title*
IS 1834 : 1984	Specification for hot applied sealing compound for joint in concrete (*first revision*)
IS 1838	Specification for preformed fillers for expansion joint in concrete pavements and structures (non extruding and resilient type):
(Part 1) : 1983	Bitumen impregnated fibre (*first revision*)
(Part 2) : 1984	CNSL aldehyde resin and coconut pith
(Part 3) : 2011	Polymer based
IS 10566 : 1983	Methods of tests for preformed fillers for expansion joint in concrete paving and structural construction
IS 10959 : 2024/ ISO 6927 : 2021	Sealants for building purposes — Glossary of terms (*second revision*)
IS 11433	Specification for one-part gun — Grade polysulphide-based joint sealants:
(Part 1) : 1985	General requirements
(Part 2) : 1986	Methods of test
IS 12118	Specification for two parts polysulphide-based sealants:
(Part 1) : 1987	General requirements
(Part 2) : 1987	Methods of test
IS 13923 : 2023	Lead seal — Specification (*first revision*)

d) Adhesives

IS No.	*Title*
IS 848 : 2025	Synthetic resin adhesives for plywood (phenolic, aminoplastic and bio-materials based) — Specification (*third revision*)
IS 851 : 1978	Specification for synthetic resin adhesives for construction work (non-structural) in wood (*first revision*)
IS 852 : 1994	Animal glue for general wood-working purposes — Specification (*second revision*)
IS 1508 : 1972	Specification for extenders for use in synthetic resin adhesives (urea-formaldehyde) for plywood (*first revision*)
IS 4835 : 1979	Specification for polyvinyl acetate dispersion-based adhesives for wood (*first revision*)
IS 5666 : 2024	Etch primer — Specification (*first revision*)
IS 9188 : 1979	Performance requirements for adhesive for structural laminated wood products for use under exterior exposure condition
IS 12830 : 1989	Rubber based adhesives for fixing PVC tiles to cement — Specification
IS 12994 : 1990	Epoxy adhesives, room temperature curing general purpose — Specification
IS 13238 : 2021	Epoxy based zinc phosphate primer (two pack) — Specification (*first revision*)
IS 15477 : 2019	Adhesives for use with ceramic tiles and mosaics (*first revision*)
IS 16239 : 2021	Polyurethane matt finish (two pack) — Specification
IS 16676 : 2024	Solventless liquid epoxy system for application on interior and exterior surfaces of steel water pipeline — Specification (*first revision*)
IS 16943 : 2019	Two components high build epoxy micaceous iron oxide (MIO) pigmented intermediate coat — Specification
IS 16944 : 2018	Two components high build epoxy titanium dioxide (TiO_2) pigmented intermediate coat — Specification
IS 17218 : 2019	Solar thermo-reflective exterior coating for cooling of roof top
IS 17545 : 2021	White cement based polymeric putty
IS 18837 : 2024	Solvent cements for chlorinated poly (vinyl chloride) (CPVC) plastic pipe and fittings

6 BUILDING LIME AND PRODUCTS

IS No.	*Title*
IS 712 : 1984	Specification for building limes (*third revision*)
IS 1624 : 1986	Method of field testing of building lime (*second revision*)
IS 2686 : 1977	Specification for cinder as fine aggregates for use in lime concrete (*first revision*)

IS No.	*Title*
IS 3068 : 1986	Specification for broken brick (burnt-clay) coarse aggregates for use in lime concrete (*second revision*)
IS 3115 : 1992	Specification for lime based blocks (*second revision*)
IS 3182 : 1986	Specification for broken bricks (burnt clay) fine aggregates for use in lime mortar (*second revision*)
IS 4098 : 1983	Specification for lime-pozzolana mixture (*first revision*)
IS 4139 : 1989	Specification for calcium silicate bricks (*second revision*)
IS 6932	Method of tests for building limes:
(Part 1) : 2025	Determination of insoluble residue in dilute acid and alkali, loss on ignition, insoluble residue in hydrochloric acid, silicon dioxide, ferric and aluminium oxide, calcium oxide and magnesium oxide (*first revision*)
(Part 2) : 2025	Determination of carbon dioxide content (*first revision*)
(Part 3) : 2025	Determination of residue on slaking of quicklime (*first revision*)
(Part 4) : 2025	Determination of fineness of hydrated lime (*first revision*)
(Part 5) : 2025	Determination of unhydrated oxide (*first revision*)
(Part 6) : 2025	Determination of volume yield of quicklime (*first revision*)
(Part 7) : 2025	Determination of compressive and transverse strength (*first revision*)
(Part 8) : 2025	Determination of workability (*first revision*)
(Part 9) : 2025	Determination of soundness (*first revision*)
(Part 10) : 2025	Determination of popping and pitting of hydrated lime (*first revision*)
(Part 11) : 2025	Determination of setting time of hydrated lime (*first revision*)
IS 10360 : 1982	Specification for lime pozzolana concrete blocks for paving
IS 10772 : 1983	Specification for quick setting lime pozzolana mixture
IS 12894 : 2002	Specification for pulverized fuel ash lime bricks (*first revision*)
IS 15648 : 2006	Pulverized fuel ash for lime-pozzolana mixture applications — Specification

7 CLAY AND STABILIZED SOIL PRODUCTS

a) Blocks

IS No.	*Title*
IS 3952 : 2013	Burnt clay hollow bricks and blocks for walls and partitions — Specification (*third revision*)

b) Stabilized Soil Products

IS No.	*Title*
IS 1725 : 2023	Stabilized soil blocks used in general building construction — Specification (*third revision*)

c) Bricks

IS No.	*Title*
IS 1077 : 2025	Common burnt clay building bricks — Specification (*sixth revision*)
IS 2180 : 1988	Specification for heavy duty burnt clay building bricks (*third revision*)
IS 2222 : 1991	Specification for burnt clay perforated building bricks (*third revision*)
IS 2691 : 2017	Burnt clay facing bricks — Specification (*third revision*)
IS 3495	Burnt clay building bricks — Method of tests
(Part 1) : 2019	Determination of compressive strength (*fourth revision*)
(Part 2) : 2019	Determination of water absorption (*fourth revision*)
(Part 3) : 2019	Determination of efflorescence (*fourth revision*)
(Part 4) : 2019	Determination of warpage (*fourth revision*)
(Part 5) : 2021	Determination of initial rate of absorption
(Part 6) : 2022	Determination of modulus of rupture
IS 3583 : 1988	Specification for burnt clay paving bricks (*second revision*)
IS 3952 : 2013	Burnt clay hollow bricks and blocks for walls and partitions — Specification (*third revision*)
IS 4885 : 1988	Specification for sewer bricks (*first revision*)
IS 5454 : 2024	Burnt clay bricks and burnt clay tiles — Methods of sampling (*second revision*)
IS 5779 : 1986	Specification for burnt clay soling bricks (*first revision*)
IS 6165 : 1992	Dimensions for special shapes of clay bricks (*first revision*)
IS 13757 : 1993	Burnt clay fly ash building bricks — Specification

d) Jallies

IS No.	*Title*
IS 7556 : 1988	Specification for burnt clay jallies (*first revision*)

e) Tiles

IS No.	*Title*
IS 654 : 2023	Clay roofing tiles Mangalore pattern — Specification (*fourth revision*)

IS No.	*Title*
IS 1464 : 2024	Clay ridge and ceiling tiles — Specification (*third revision*)
IS 1478 : 2023	Clay flooring tiles — Specification (*third revision*)
IS 2690	Burnt clay flat terracing tiles — Specification
(Part 1) : 2023	Machine made (*third revision*)
(Part 2) : 2023	Hand made (*second revision*)
IS 3367 : 2023	Burnt clay tiles for use in lining irrigation and drainage works — Specification (*third revision*)
IS 3951	Hollow clay tiles for floor and roofs — Specification
(Part 1) : 2023	Filler type (*third revision*)
(Part 2) : 2023	Structural type (*third revision*)
IS 8920 : 1978	Methods for sampling of burnt clay tiles
IS 13317 : 2023	Clay roofing county tiles half round and flat tiles — Specification (*first revision*)
IS 17190 : 2020	Grouts for filling of joints of tiles and stones — Specification
IS 17897 : 2022	Stone-polymer composite flooring tiles and planks — Specification
IS 18387 : 2023	Gypsum ceiling tiles — Specification

8 CEMENT AND CONCRETE (INCLUDING STEEL REINFORCEMENT FOR CONCRETE)

a) Aggregates

IS No.	*Title*
IS 383 : 2016	Coarse and fine aggregate for concrete — Specification (*third revision*)
IS 4961 : 2022	Determination of particle size of powders by air elutriation methods (*first revision*)
IS 650 : 1991	Specification for standard sand for testing of cement (*second revision*)
IS 1542 : 1992	Specification for sand for plaster (*second revision*)
IS 2116 : 1980	Specification for sand for masonry mortars (*first revision*)
IS 2386	Methods of test for aggregates for concrete:
(Part 1) : 1963	Particle size and shape
(Part 2) : 1963	Estimation of deleterious materials and organic impurities
(Part 3) : 1963	Specific gravity, density, voids, absorption and bulking
(Part 4) : 1963	Mechanical properties
(Part 5) : 1963	Soundness

IS No.	*Title*
(Part 6) : 1963	Measuring mortar making properties of fine aggregates
(Part 7) : 1963	Alkali aggregate reactivity
(Part 8) : 1963	Petrographic examination
IS 2430 : 1986	Methods of sampling of aggregates of concrete (*first revision*)
IS 4879 : 2023	Particulate materials — Sampling and sample splitting technique (*first revision*)
IS 5282	Determination of particle size distribution by gravitational liquid sedimentation methods:
(Part 1) : 2023	General principles and guidelines (*first revision*)
(Part 2) : 2023	Fixed pipette method (*first revision*)
(Part 3) : 2023	X-Ray gravitational technique *(first revision)*
(Part 4) : 2023	Balance method *(first revision)*
IS 6579 : 1981	Specification for coarse aggregate for water bound macadam (*first revision*)
IS 9142	Artificial light-weight aggregates for concrete — Specification:
(Part 1) : 2018	For concrete masonry blocks and for applications other than for structural concrete (*first revision*)
(Part 2) : 2018	Sintered fly ash coarse aggregate (*first revision*)
IS 10086 : 2021	Specification for moulds for use in tests of cement and concrete (*first revision*)
IS 18657	Representation of results of particle size analysis:
(Part 1) : 2024/ ISO 9276-1 : 1998	Graphical representation
(Part 2) : 2024/ ISO 9276-2 : 2014	Calculation of average particle sizes/diameters and moments from particle size distributions
(Part 3) : 2024/ ISO 9276-3 : 2008	Adjustment of an experimental curve to a reference model
(Part 4) : 2024/ ISO 9276-4 : 2001	Characterization of a classification process
(Part 5) : 2024/ ISO 9276-5 : 2005	Methods of calculation relating to particle size analyses using logarithmic normal probability distribution
(Part 6) : 2024/ ISO 9276-6 : 2008	Descriptive and quantitative representation of particle shape and morphology

b) Cement

IS No.	*Title*
IS 269 : 2015	Ordinary portland cement — Specification (*sixth revision*)
IS 455 : 2015	Portland slag cement — Specification (*fifth revision*)

IS 1489	Portland pozzolana cement — Specification:
(Part 1) : 2015	Flyash based (*fourth revision*)
(Part 2) : 2015	Calcined clay based (*fourth revision*)
IS 3466 : 2026	Masonry cement — Specification (*third revision*)
IS 6452 : 1989	Specification for high alumina cement for structural use (*first revision*)
IS 6909 : 2026	Supersulphated cement — Specification (*second revision*)
IS 8041 : 2026	Rapid hardening portland cement — Specification (*third revision*)
IS 8042 : 2015	White portland cement — Specification (*third revision*)
IS 8043 : 2026	Hydrophobic portland cement — Specification (*third revision*)
IS 12330 : 1988	Specification for sulphate resisting portland cement
IS 12600 : 1989	Portland cement, low heat — Specification
IS 16415 : 2015	Composite cement — Specification
IS 16993 : 2018	Microfine ordinary portland cement — Specification
IS 17908 : 2023	Fibre cement sheet — Lightweight concrete sandwich panels specification
IS 18189 : 2023	Portland calcined clay limestone cement — Specification

c) Supplementary Cementitious Materials (Mineral Admixtures and Pozzolanas)

IS No.	*Title*
IS 1344 : 1981	Specification for calcined clay pozzolana (*second revision*)
IS 1727 : 1967	Methods of test for pozzolanic materials (*first revision*)
IS 3812	Pulverized fuel ash — Specification:
(Part 1) : 2013	For use as pozzolana in cement, cement mortar and concrete (*third revision*)
(Part 2) : 2013	For use as admixture in cement mortar and concrete (*third revision*)
IS 6491 : 1972	Method of sampling of flyash
IS 12089 : 1987	Specification for granulated slag for manufacture of portland slag cement
IS 12870 : 1989	Methods of sampling calcined clay pozzolana
IS 15388 : 2003	Specification for silica fume
IS 16354 : 2015	Metakaolin for use in cement, cement mortar and concrete — Specification
IS 16714 : 2018	Ground granulated blast furnace slag for use in cement mortar and concrete — Specification
IS 16715 : 2018	Ultrafine ground granulated blast furnace slag — Specification
IS 19058 : 2024	Ultrafine fly ash — Specification

d) Chemical Admixtures

IS No.	*Title*
IS 6925 : 1973	Methods of test for determination of water soluble chlorides in concrete admixtures
IS 9103 : 1999	Specification for admixtures for concrete (*first revision*)

e) Concrete

IS No.	*Title*
IS 456 : 2000	Code of practice for plain and reinforced concrete (*fourth revision*)
IS 1343 : 2012	Code of practice for prestressed concrete (*second revision*)
IS 4926 : 2003	Code of practice for ready-mixed concrete (*second revision*)

f) Cement and Concrete Sampling and Methods of Test

IS No.	*Title*
IS 516	Hardened concrete methods of test:
(Part 1/Sec 1) : 2021	Testing of strength of hardened concrete, Section 1 Compressive, flexural and split tensile strength (*first revision*)
(Part 2)	Properties of hardened concrete other than strength,
(Sec 1) : 2018	Density of hardened concrete and depth of water penetration under pressure (*first revision*)
(Sec 2) : 2020	Initial surface absorption (*first revision*)
(Sec 3) : 2022	Oxygen permeability index (*first revision*)
(Sec 4) : 2021	Determination of the carbonation resistance by accelerated carbonation method (*first revision*)
(Part 4) : 2018	Sampling preparing and testing of concrete cores (*first revision*)
(Part 5)	Non-destructive testing of concrete,
(Sec 1) : 2018	Ultrasonic pulse velocity testing (*first revision*)
(Sec 2) : 2021	Half-cell potentials of uncoated reinforcing steel in concrete (*first revision*)
(Sec 3) : 2021	Carbonation depth test (*first revision*)
(Sec 4) : 2020	Rebound hammer test (*first revision*)
(Part 6) : 2020	Determination of drying shrinkage and moisture movement of concrete samples (*first revision*)
(Part 8/Sec 1) : 2020	Determination of modulus of elasticity, Section 1 Static modulus of elasticity and poissons ratio in compression (*first revision*)
(Part 11) : 2020	Determination of portland cement content of hardened hydraulic cement concrete (*first revision*)

IS No.	*Title*
IS 1199	Fresh concrete — Methods of sampling testing and analysis:
(Part 1) : 2018	Sampling of fresh concrete (*first revision*)
(Part 2) : 2018	Determination of consistency of fresh concrete (*first revision*)
(Part 3) : 2018	Determination of density of fresh concrete (*first revision*)
(Part 4) : 2018	Determination of air content of fresh concrete (*first revision*)
(Part 5) : 2018	Making and curing of test specimens (*first revision*)
(Part 6) : 2018	Tests on fresh self-compacting concrete (*first revision*)
(Part 7) : 2018	Determination of setting time of concrete by penetration resistance (*first revision*)
IS 2770 (Part 1) : 1967	Methods of testing bond in reinforced concrete: Part 1 Pullout test
IS 3085 : 1965	Methods of test for permeability of cement mortar and concrete
IS 3535 : 1986	Methods of sampling hydraulic cement (*first revision*)
IS 4031	Methods of physical tests for hydraulic cement:
(Part 1) : 1996	Determination of fineness by dry sieving (*second revision*)
(Part 2) : 1999	Determination of fineness by specific surface by Blaine air permeability method (*second revision*)
(Part 3) : 1988	Determination of soundness (*first revision*)
(Part 4) : 1988	Determination of consistency of standard cement paste (*first revision*)
(Part 5) : 1988	Determination of initial and final setting times (*first revision*)
(Part 6) : 1988	Determination of compressive strength of hydraulic cement (other than masonry cement) (*first revision*)
(Part 7) : 1988	Determination of compressive strength of masonry cement (*first revision*)
(Part 8) : 1988	Determination of transverse and compressive strength of plastic mortar using prism (*first revision*)
(Part 9) : 1988	Determination of heat of hydration (*first revision*)
(Part 10) : 1988	Determination of drying shrinkage (*first revision*)
(Part 11) : 1988	Determination of density (*first revision*)
(Part 12) : 1988	Determination of air content of hydraulic cement mortar (*first revision*)
(Part 13) : 1988	Measurement of water retentivity of masonry cement (*first revision*)
(Part 14) : 1989	Determination of false set
(Part 15) : 1991	Determination of fineness by wet sieving
IS 4032 : 1985	Methods of chemical analysis for hydraulic cement (*first revision*)
IS 5816 : 1999	Method of test for splitting tensile strength of concrete (*first revision*)

IS No.	*Title*
IS 9013 : 1978	Method of making, curing and determining compressive strength of accelerated cured concrete test specimens
IS 9284 : 1979	Method of test for abrasion resistance of concrete
IS 12423 : 1988	Methods for colorimetric analysis of hydraulic cement
IS 12803 : 1989	Methods of analysis of hydraulic cement by X-ray fluorescence spectrometer
IS 12813 : 1989	Method of analysis of hydraulic cement by atomic absorption spectrophotometer
IS 13311	Methods of non-destructive testing of concrete:
(Part 2) : 1992	Rebound hammer
IS 14959	Method of test for determination of water soluble and acid soluble chlorides in mortar and concrete
(Part 1) : 2001	Fresh mortar and concrete
(Part 2) : 2001	Hardened mortar and concrete
IS 17161 : 2020	Flexural strength and toughness parameters of fibre reinforced concrete — Method of test
IS 17725 : 2022	Precast concrete circular manhole — Specification

g) Treatment of Concrete Joints

IS No.	*Title*
IS 1834 : 1984	Specification for hot applied sealing compound for joint in concrete (*first revision*)
IS 1838	Specification for preformed fillers for expansion joint in concrete pavements and structures (non extruding and resilient type):
(Part 1) : 1983	Bitumen impregnated fibre (*first revision*)
(Part 2) : 1984	CNSL aldehyde resin and coconut pith
(Part 3) : 2011	Polymer based
IS 10566 : 1983	Methods of test for preformed fillers for expansion joints in concrete paving and structural construction
IS 11433	Specification for one grade polysulphide based joint sealant:
(Part 1) : 1985	General requirements
(Part 2) : 1986	Methods of test
IS 12118	Specification for two parts polysulphide based sealants:
(Part 1) : 1987	General requirements
(Part 2) : 1987	Methods of test

h) Steel Reinforcement for Concrete

IS No.	*Title*
IS 432	Specification for mild steel and medium tensile steel bars and hard drawn steel wire for concrete reinforcement:
(Part 1) : 1982	Mild steel and medium tensile steel bars (*third revision*)
(Part 2) : 1982	Hard drawn steel wire (*third revision*)
IS 1566 : 1982	Specification for hard drawn steel wire fabric for concrete reinforcement (*second revision*)
IS 1599 : 2023/ ISO 7438 : 2020	Metallic materials — Bend test (*fifth revision*)
IS 1608	Metallic materials — Tensile testing:
(Part 1) : 2022/ ISO 6892-1 : 2019	Method of test at room temperature (*fifth revision*)
(Part 2) : 2020/ ISO 6892-2 : 2018	Method of test at elevated temperature (*fourth revision*)
(Part 3) : 2018/ ISO 6892-3 : 2015	Method of test at low temperature
IS 1785	Specification for plain hard drawn steel wire for pre-stressed concrete:
(Part 1) : 1983	Cold drawn stress-relieved wire (*second revision*)
(Part 2) : 1983	As drawn wire (*first revision*)
IS 1786 : 2008	High strength deformed steel bars and wires for concrete reinforcement Specification (*fourth revision*)
IS 2090 : 1983	Specification for high tensile steel bars used in prestressed concrete (*first revision*)
IS 6003 : 2010	Indented wire for prestressed concrete — Specification (*second revision*)
IS 6006 : 2014	Uncoated stress-relieved strand for prestressed concrete — Specification (*second revision*)
IS 9417 : 2018	Welding of high strength steel bars for reinforced concrete construction — Recommendations (*second revision*)
IS 10790	Methods of sampling of steel for prestressed and reinforced concrete:
(Part 1) : 1984	Prestressing steel
(Part 2) : 1984	Reinforcing steel
IS 12594 : 1988	Hot-dip zinc coating on structural steel bars for concrete reinforcement — Specification
IS 13620 : 1993	Specification for fusion bonded epoxy coated reinforcing bars
IS 14268 : 2022	Uncoated stress relieved low relaxation seven-wire ply strand for prestressed concrete — Specification (*second revision*)

IS No.	*Title*
IS 16172 : 2023	Reinforcement couplers for mechanical splices of steel bars in concrete — Specification (*first revision*)
IS 16644 : 2018	Stress-Relieved low relaxation steel wire for prestressed concrete — Specification
IS 16651 : 2017	High strength deformed stainless steel bars and wires for concrete reinforcement — Specification
IS 18255 : 2023	Fibre-Reinforced Polymer FRP bars for concrete reinforcement — Methods of test
IS 18256 : 2023	Solid round glass fibre reinforced polymer GFRP bars for concrete reinforcement — Specification
IS 19068 : 2025	Continuous Hot-dip galvanized steel bars for concrete reinforcement — Specification

9 COMPOSITE MATRIX PRODUCTS

a) Cement Matrix Products

i) *Precast Concrete Products*

IS No.	*Title*
IS 2174 : 1962	Specification for reinforced concrete dust bins
IS 2185	Specification for concrete masonry units:
(Part 1) : 2005	Hollow and solid concrete blocks (*third revision*)
(Part 2) : 1983	Hollow and solid lightweight concrete blocks (*first revision*)
(Part 3) : 1984	Autoclaved cellular (aerated) concrete blocks (*first revision*)
(Part 4) : 2008	Preformed foam cellular concrete blocks
IS 4996 : 1984	Specification for reinforced concrete fence posts (*first revision*)
IS 5751 : 1984	Specification for precast concrete coping blocks (*first revision*)
IS 5758 : 2020	Precast concrete kerbs channels edging quadrants and other associated fittings — Specification (*second revision*)
IS 5820 : 2024	Precast concrete cable covers — Specification (*first revision*)
IS 6072 : 2023	Autoclaved reinforced cellular concrete wall slabs — Specification (*first revision*)
IS 6073 : 2006	Specification for autoclaved reinforced cellular concrete floor and roof slabs (*first revision*)
IS 6441	Methods of test for autoclaved cellular concrete products:
(Part 1) : 1972	Determination of unit weight or bulk density and moisture content
(Part 2) : 1972	Determination of drying shrinkage

IS No.	*Title*
(Part 4) : 1972	Corrosion protection of steel reinforcement in autoclaved cellular concrete
(Part 5) : 1972	Determination of compressive strength
(Part 6) : 1973	Strength, deformation and cracking of flexural members subject to bending-short duration loading test
(Part 7) : 1973	Strength, deformation and cracking of flexural members subject to bending-sustained loading test
(Part 8) : 1973	Loading tests for flexural members in diagonal tension
(Part 9) : 1973	Jointing of autoclaved cellular concrete elements
IS 6523 : 1983	Specification for precast reinforced concrete door and window frames (*first revision*)
IS 9375 : 1979	Specification for precast reinforced concrete plant guards
IS 9872 : 1981	Specification for precast concrete septic tanks
IS 9893 : 1981	Specification for precast concrete blocks for lintels and sills
IS 12440 : 1988	Specification for precast concrete stone masonry blocks
IS 12592 : 2002	Specification for precast concrete manhole covers and frames (*first revision*)
IS 13356 : 1992	Specification for precast ferrocement water tanks (250 litres to 10 000 litres capacity)
IS 13990 : 1994	Specification for precast reinforced concrete planks and joists for flooring and roofing
IS 14143 : 1994	Specification for prefabricated brick panel and partially precast concrete joist for flooring and roofing
IS 14201 : 1994	Specification for precast reinforced concrete channel unit for construction of floors and roofs
IS 14241 : 1995	Specification for precast L-Panel units for roofing
IS 18661 : 2024	Precast concrete grating — Specification
IS 18889 : 2024	Precast concrete paving flags — Specification
IS 18894 : 2024	Precast concrete paving grids and grass pavers — Specification

ii) *Asbestos Fibre Cement Products*

IS No.	*Title*
IS 459 : 1992	Specification for corrugated and semi-corrugated asbestos cement sheets (*third revision*)
IS 1592 : 2003	Specification for asbestos cement pressure pipes and joints (*fourth revision*)
IS 1626	Specification for asbestos cement building pipes and pipe fittings, gutters and gutter fittings and roofing fittings:

IS No.	*Title*
(Part 1) : 1994	Pipes and pipe fittings (*second revision*)
(Part 2) : 1994	Gutters and gutter fittings (*second revision*)
(Part 3) : 1994	Roofing fittings (*second revision*)
IS 2096 : 1992	Specification for asbestos cement flat sheets (*first revision*)
IS 2098 : 1997	Specification for asbestos cement building boards (*first revision*)
IS 5913 : 2003	Methods of test for asbestos cement products (*second revision*)
IS 6908 : 1991	Specification for asbestos cement pipes and fittings for sewerage and drainage (*first revision*)
IS 7639 : 1975	Method of sampling asbestos cement products
IS 9627 : 1980	Specification for asbestos cement pressure pipes (light duty)
IS 13000 : 1990	Silica-asbestos-cement flat sheets — Specification
IS 13008 : 1990	Specification for shallow corrugated asbestos cement sheets

iii) *Other Fibre Cement Products*

IS No.	*Title*
IS 14862 : 2000	Specification for fibre cement flat sheets
IS 14871 : 2000	Specification for products in fibre reinforced cement long corrugated or asymmetrical section sheets and fittings for roofing and cladding

iv) *Concrete Pipes and Pipes Lined/Coated with Concrete or Mortar*

IS No.	*Title*
IS 458 : 2021	Precast concrete pipes with and without reinforcement (*fifth revision*)
IS 784 : 2019	Prestressed concrete pipes including specials — Specification (*third revision*)
IS 1916 : 2018	Steel cylinder pipes with concrete lining and coating — Specification (*second revision*)
IS 3597 : 1998	Methods of test for concrete pipes (*second revision*)
IS 4350 : 1967	Specification for concrete porous pipes for under drainage
IS 7319 : 1974	Specification for perforated concrete pipes
IS 7322 : 1985	Specification for specials for steel cylinder reinforced concrete pipes (*first revision*)
IS 15155 : 2020	Barwire wrapped steel cylinder pipes with mortar lining and coating including specials specification (*first revision*)

b) Resin Matrix Products

IS No.	*Title*
IS 1998 : 1962	Methods of test for thermosetting synthetic resin bonded laminated sheets
IS 2036 : 1995	Specification for phenolic laminated sheets (*second revision*)
IS 2046	Decorative thermosetting synthetic resin bonded laminated sheets — Specification:
(Part 1) : 2025/ ISO 4586-1 : 2018	Introduction and general information (*third revision*)
(Part 2) : 2025/ ISO 4586-2 : 2018	Determination of properties (*third revision*)
(Part 3) : 2025/ ISO 4586-3 : 2018	Classification and specifications for laminates less than 2 mm thick and intended for bonding to supporting substrates (*third revision*)
(Part 4) : 2025 ISO 4586-4 : 2018	Classification and specifications for compact laminates of thickness 2 mm and greater (*third revision*)
(Part 5) : 2025 ISO 4586-5 : 2018	Classification and specifications for flooring grade laminates less than 2 mm thick intended for bonding to supporting substrates (*third revision*)
(Part 6) : 2025 ISO 4586-6 : 2018	Classification and specifications for exterior-grade compact laminates of thickness 2 mm and greater (*third revision*)
(Part 7) : 2025 ISO 4586-7 : 2018	Classification and specifications for design laminates (*third revision*)
(Part 8) : 2025 ISO 4586-8 : 2018	Classification and specifications for alternative core laminates (*third revision*)

10 CONDUCTORS AND CABLES

IS No.	*Title*
IS 694 : 2010	Polyvinyl chloride insulated unsheathed and sheathed cables/cords with rigid and flexible conductor for rated voltages up to and including 450/750 V (*fourth revision*)
IS 1554	Specification for PVC insulated (heavy duty) electric cables:
(Part 1) : 1988	For working voltages up to and including 1 100 volts (*third revision*)
(Part 2) : 1988	For working voltages from 3.3 kV up to and including 11 kV (*second revision*)
IS 3961	Recommended current ratings for cables:
(Part 2) : 2017	PVC insulated and PVC sheathed heavy duty cables (*first revision*)
(Part 3) : 1968	Rubber insulated cables
(Part 5) : 1968	PVC insulated light duty cables
(Part 6) : 2016	Crosslinked polyethylene insulated PVC sheathed cables
(Part 7) : 2017	Crosslinked polyethylene insulated thermoplastic sheathed cables

IS No.	*Title*
IS 4289	Specification for flexible cables for lifts and other flexible connections:
(Part 1) : 1984	Elastomer insulated cables (*first revision*)
(Part 2) : 2000	PVC insulated circular cables
IS 7098	Cross-linked polyethylene insulated sheathed cables — Specification
(Part 1) : 2025	For working voltage up to and including 1 100 V (*second revision*)
(Part 2) : 2011	For working voltages form 3.3 kV up to and including 33 kV (*second revision*)
(Part 3) : 1993	For working voltages from 66 kV upto and including 220 kV
IS 9968	Elastomer insulated cables — Specification:
(Part 1) : 2025	For working voltages up to and including 1 100 V (*second revision*)
(Part 2) : 2002	For working voltages from 3.3 kV up to and including 33 kV (*first revision*)
IS 10810	Methods of test for cables:
(Part 0) : 1984	General
(Part 1) : 1984	Annealing test for wires used in conductors
(Part 2) : 1984	Tensile test for aluminium wires
(Part 3) : 1984	Wrapping test for aluminium wires
(Part 4) : 1984	Persulphate test of conductor
(Part 5) : 1984	Conductor resistance test
(Part 6) : 1984	Thickness of thermoplastic and elastomeric insulation and sheath
(Part 7) : 1984	Tensile strength and elongation at break of thermoplastic and elastomeric insulation and sheath
(Part 8) : 1984	Breaking strength and elongation at break for impregnated paper insulation
(Part 9) : 1984	Tear resistance for paper insulation
(Part 10) : 1984	Loss of mass test
(Part 11) : 1984	Thermal ageing in air
(Part 12) : 1984	Shrinkage test
(Part 13) : 1984	Ozone resistance test
(Part 14) : 1984	Heat shock test
(Part 15) : 1984	Hot deformation test
(Part 16) : 1986	Accelerated ageing test by oxygen pressure method
(Part 17) : 1986	Tear resistance test for heavy duty sheath

IS No.	*Title*
(Part 19) : 1984	Bleeding and blooming test
(Part 20) : 1984	Cold bend test
(Part 21) : 1984	Cold impact test
(Part 22) : 1984	Vicat softening point
(Part 23) : 1984	Melt-flow index
(Part 24) : 1984	Water soluble impurities test of insulating paper
(Part 25) : 1984	Conductivity of water extract test of insulating paper
(Part 26) : 1984	*p*H value of water extract test of insulating paper
(Part 27) : 1984	Ash content test of insulating paper
(Part 28) : 1984	Water absorption test (Electrical)
(Part 29) : 1984	Environmental stress cracking test
(Part 30) : 1984	Hot set test
(Part 31) : 1984	Oil resistance test
(Part 32) : 1984	Carbon content test for polyethylene
(Part 33) : 1984	Water absorption test (Gravimetric)
(Part 34) : 1984	Measurement of thickness of metallic sheath
(Part 35) : 1984	Determination of tin in lead alloy for sheathing
(Part 36) : 1984	Dimensions of armouring material
(Part 37) : 1984	Tensile strength and elongation at break of armouring materials
(Part 38) : 1984	Torsion test on galvanized steel wires for armouring
(Part 39) : 1984	Winding test on galvanized steel strips for armouring
(Part 40) : 1984	Uniformity of zinc coating on steel armour
(Part 41) : 1984	Mass of zinc coating on steel armour
(Part 42) : 1984	Resistivity test of armour wires and strips and conductance test of armour (wires/strips)
(Part 43) : 1984	Insulation resistance
(Part 44) : 1984	Spark test
(Part 45) : 1984	High voltage test
(Part 46) : 1984	Partial discharge test
(Part 47) : 1984	Impulse test

IS No.	*Title*
(Part 48) : 1984	Dielectric power factor test
(Part 49) : 1984	Heating cycle test
(Part 50) : 1984	Bending test
(Part 51) : 1984	Dripping test
(Part 53) : 1984	Flammability test
(Part 54) : 1984	Static flexibility test
(Part 55) : 1986	Abrasion test
(Part 56) : 1987	Accelerated ageing by the air-pressure method
(Part 57) : 1987	Flexing test
(Part 58) : 1998	Oxygen index test
(Part 59) : 1988	Determination of the amount of halogen acid gas evolved during combustion of polymeric materials taken from cables
(Part 60) : 1988	Thermal stability of PVC insulation and sheath
(Part 61) : 1988	Flame retardant test
(Part 62) : 1993	Fire resistance test for bunched cables
(Part 63) : 1993	Smoke density of electric cables under fire conditions
(Part 64) : 2003	Measurement of temperature index
IS 12943 : 1990	Brass glands for PVC cables — Specification
IS 14763 : 2022	Conduit systems for cable management outside diameters of conduits for electrical installations and threads for conduits and fittings
IS 16205	Conduit systems for cable management:
(Part 1) : 2017	General requirements
(Part 21) : 2017	Particular requirements rigid conduit systems
(Part 22) : 2017	Particular requirements — Pliable conduit systems
(Part 23) : 2017	Particular requirements flexible conduit systems
(Part 24) : 2017	Particular requirements conduit systems buried under ground
IS 16783 : 2018	Cable cleats for electrical installations
IS 17048 : 2018	Halogen free flame retardant HFFR cables for working voltages up to and including 1 100 Volts — Specification
IS 17293 : 2020	Electric cables for photovoltaic systems for rated voltage 1 500 V d. c.

IS No.	*Title*
IS 17505 (Part 1) : 2021	Specification for thermosetting insulated fire survival cables for fixed installation having low emission of smoke and corrosive gases when affected by fire for working voltages upto and including 1 100 V a.c. and 1 500 V d.c.: Part 1 Requirements for armoured cables
IS 18833 : 2024/ IEC 62895 : 2017	High voltage direct current (HVDC) power transmission — Cables with extruded insulation and their accessories for rated voltages up to 320 kV for land applications — Test methods and requirements
IS/IEC 60371-3-7 : 1995	Specification for insulating materials based on MICA: Part 3 Specifications for Individual materials, Section 7 Polyester film mica paper with an epoxy resin binder for single conductor taping
IS/IEC 60371-3-8 : 1995	Specification for insulating materials based on MICA: Part 3 Specification for individual materials, Section 8 Mica paper tapes for flame resistant security cables
IS/IEC 62275 : 2018	Cable management systems — Cable ties for electrical installations (*first revision*)

11 DOORS, WINDOWS AND VENTILATORS

a) Wooden Doors, Windows and Ventilators

IS No.	*Title*
IS 1003	Specification for timber panelled and glazed shutters
(Part 1) : 2003	Door shutters (*fourth revision*)
(Part 2) : 1994	Window and ventilator shutters (*third revision*)
IS 2191	Wooden flush door shutters (cellular, hollow and tubular core type) — Specification
(Part 1) : 2022	Plywood face panels (*fifth revision*)
(Part 2) : 2022	Particle board high density fibre board medium density fibre board and fibre hardboard face panels (*fourth revision*)
IS 2202	Wooden flush door shutters solid core type — Specification
(Part 1) : 2023	Plywood face panels (*seventh revision*)
(Part 2) : 2022	Particle board high density fibre board medium density fibre board and hardboard face panels (*fourth revision*)
IS 4020	Method of tests for door shutters:
(Part 1) : 1998	General (*third revision*)
(Part 2) : 1998	Measurement of dimensions and squareness (*third revision*)
(Part 3) : 1998	Measurement of general flatness (*third revision*)
(Part 4) : 1998	Local planeness test (*third revision*)
(Part 5) : 1998	Impact indentation test (*third revision*)

IS No.	*Title*
(Part 6) : 1998	Flexure test (*third revision*)
(Part 7) : 1998	Edge loading test (*third revision*)
(Part 8) : 1998	Shock resistance test (*third revision*)
(Part 9) : 1998	Buckling resistance test (*third revision*)
(Part 10) : 1998	Slamming test (*third revision*)
(Part 11) : 1998	Misuse test (*third revision*)
(Part 12) : 1998	Varying humidity test (*third revision*)
(Part 13) : 1998	End immersion test (*third revision*)
(Part 14) : 1998	Knife test (*third revision*)
(Part 15) : 1998	Glue adhesion test (*third revision*)
(Part 16) : 1998	Screw withdrawal resistance test (*third revision*)
IS 4021 : 1995	Specification for timber door, window and ventilator frames (*third revision*)
IS 6198 : 1992	Specification for ledged, braced and battened timber door shutters (*second revision*)

b) Metal Doors, Windows Frames and Ventilators

IS No.	*Title*
IS 1038 : 1983	Specification for steel doors, windows and ventilators (*third revision*)
IS 1361 : 1978	Specification for steel windows for industrial buildings (*first revision*)
IS 1948 : 2024	Aluminium framed doors, windows and sliders — Specification (*first revision*)
IS 4351 : 2024	Steel Frames for Doors — Specification (*third revision*)
IS 6248 : 1979	Specification for metal rolling shutters and rolling grills (*first revision*)
IS 7452 : 1990	Specification for hot rolled steel sections for doors, windows and ventilators (*second revision*)
IS 10451 : 1983	Specification for steel sliding shutters (top hung type)
IS 10521 : 1983	Specification for collapsible gates
IS 18648 : 2024	Classification and performance requirements for doors, windows and sliders — Specification

c) Plastic Doors and Windows

IS No.	*Title*
IS 14856 : 2000	Specification for glass fibre reinforced plastic (GRP) panel type door shutters for internal use

IS 15380 : 2023	Moulded high density fibre HDF panelled door shutters — Specification (*first revision*)
IS 15931 : 2012	Solid panel foam UPVC door shutters — Specification
IS 17953 : 2023	uPVC profiles for windows and doors — Specification
IS 18648 : 2024	Classification and performance requirements for doors, windows and sliders — Specification

d) Concrete Doors and Windows

IS No.	*Title*
IS 6523 : 1983	Specification for precast reinforced concrete door and window frames (*first revision*)

e) Other Composite Material Doors and Windows

IS No.	*Title*
IS 16073 : 2013	Bamboo-jute composite panel door shutter — Specification
IS 16074 : 2024	Steel flush door shutters — Specification (*first revision*)
IS 16096 : 2013	Bamboo-Jute composite hollow core door shutter — Specification

f) Fire Check Doors

IS No.	*Title*
IS 3614 : 2021	Fire doors and doorsets — Specification (*first revision*)

g) Mesh/Net for Mosquito/Vector Prevention

IS No.	*Title*
IS 1568 : 1970	Specification for wire cloth for general purposes (*first revision*)
IS 3150 : 1982	Specification for hexagonal wire netting for general purposes (*second revision*)
IS 11199 : 2024	Textiles — High density polyethylene (HDPE) monofilament twine door nets — Specification (*first revision*)

h) Doors and Windows — Method of tests

IS No.	*Title*
IS 4020	Method of tests for door shutters:
(Part 1) : 1998	General (*third revision*)
(Part 2) : 1998	Measurement of dimensions and squareness (*third revision*)
(Part 3) : 1998	Measurement of general flatness (*third revision*)
(Part 4) : 1998	Local planeness test (*third revision*)
(Part 5) : 1998	Part 5 Impact indentation test (*third revision*)

IS No.	*Title*
(Part 6) : 1998	Flexure test (*third revision*)
(Part 7) : 1998	Edge loading test (*third revision*)
(Part 8) : 1998	Shock resistance test (*third revision*)
(Part 9) : 1998	Buckling resistance test (*third revision*)
(Part 10) : 1998	Slamming test (*third revision*)
(Part 11) : 1998	Misuse test (*third revision*)
(Part 12) : 1998	Varying humidity test (*third revision*)
(Part 13) : 1998	End immersion test (*third revision*)
(Part 14) : 1998	Knife test (*third revision*)
(Part 15) : 1998	Glue adhesion test (*third revision*)
(Part 16) : 1998	Screw withdrawal resistance test (*third revision*)
IS 12458 : 2019	Fire resistance of through penetration firestops — Method of test (*first revision*)
IS 17518 (Part 1) : 2022/ ISO 3008-1 : 2019	Fire resistance tests — Door and shutter assemblies: Part 1 General requirements
IS 17909 : 2022/ ISO 8274 : 2005	Windows and doors — Resistance to repeated opening and closing — Test method
IS 17910	Thermal performance of windows and doors — Determination of thermal transmittance by the hot-box method:
(Part 1) : 2022/ ISO 12567-1:2010	Complete windows and doors
(Part 2) : 2022/ ISO 12567-2 : 2005	Roof windows and other projecting windows
IS 17911 : 2022/ ISO 15099 : 2003	Thermal performance of windows, doors and shading devices — Detailed calculations
IS 17920 : 2022/ ISO 10077-2 : 2017	Thermal performance of windows, doors and shutters — Calculation of thermal transmittance — Numerical method for frames
IS 18268 : 2023/ ISO 9379 : 2005	Operating forces — Test methods — Doors
IS 18434 : 2023	Field measurement of air permeability and water penetration through installed curtain wall, windows, doors, sliders and skylights under static air pressure difference — Method of test
IS 18459 : 2024	Water penetration of curtain walls, windows, sliders, doors and skylights by uniform static air pressure difference — Method of test
IS 18473 : 2024	Wind resistance for curtain walls, windows, sliders, doors and skylights — Method of test

IS No.	*Title*
IS 18647 : 2024	Water penetration of curtain walls, windows, sliders and doors by dynamic air pressure — Method of test
IS 18648 : 2024	Classification and performance requirements for doors, windows and sliders — Specification
IS 19006 : 2023/ISO 8248 : 1985	Windows and door height windows — Mechanical tests

12 ELECTRICAL WIRING, FITTINGS AND ACCESSORIES

IS No.	*Title*
IS 302 (Part 1) : 2024/ IEC 60335-1 : 2020	Household and similar electrical appliances — Safety: Part 1 General requirements (*seventh revision*)
IS 302	Safety of household and similar electrical appliances:
(Part 2)	Particular requirements,
(Sec 21) : 2024/ IEC 60335-2-21 : 2022	Storage water heaters (*third revision*)
(Sec 35) : 2017	Electric instantaneous water heaters (*second revision*)
(Sec 74) : 2024/ IEC 60335-2-74 : 2021	Portable immersion heaters
IS 302-2-80 : 2017	Household and similar electrical appliances — Safety: Part 2-80 Particular requirements for fans (*first revision*)
IS 369 : 2019	Household electric direct — Acting room heaters — Performance requirements (*fourth revision*)
IS 371 : 1999	Specification for ceiling roses (*third revision*)
IS 374 : 2019	Specification for electric ceiling type fans and regulators (*third revision*)
IS 418 : 2004	Specification for tungsten filament lamp for domestic and similar general lighting purposes (*fourth revision*)
IS 1258 : 2024/ IEC 61184 : 2017	Bayonet lampholders (*fifth revision*)
IS 1293 : 2019	Plugs and socket-outlets of rated voltage up to and including 250 volts and rated current up to and including 16 amperes — Specification (*fourth revision*)
IS 1554	PVC insulated (heavy duty) electric cables:
(Part 1) : 1988	For working voltages upto and including 1 100 V (*third revision*)
(Part 2) : 1988	For working voltages from 3.3 kV upto and including 11 kV (*second revision*)
IS 2082 : 2018	Stationary storage type electric water heaters — Specification (*fifth revision*)
IS 2086 : 1993	Specification for carriers and bases used in re-wirable type electric fuses up to 650 volts (*third revision*)
IS 2215 : 2006	Specification for starters for fluorescent lamps (*third revision*)
IS 2418	Tubular fluorescent lamps for general lighting service:

IS No.	*Title*
(Part 1) : 2018	Safety requirements (*second revision*)
(Part 2) : 2018	Performance requirements (*second revision*)
(Part 3) : 1977	Dimensions of G-5 and G-13 bi-pin caps (*first revision*)
(Part 4) : 1977	Go and no-go gauges for G-5 and G-13 bi-pin caps (*first revision*)
IS 3323 : 1980	Specification for bi-pin lamp holders for tubular fluorescent lamps (*first revision*)
IS 3324 : 1982	Specification for holders for starters for tubular fluorescent lamps (*first revision*)
IS 3419 : 1988	Specification for fittings for rigid non-metallic conduits (*second revision*)
IS 3480 : 2024	Flexible steel conduits for electrical wiring — Specification (*first revision*)
IS 3724 : 2017	Cartridge type heating elements (non-embedded type) — Specification (*first revision*)
IS 3837 : 1976	Specification for accessories for rigid steel conduits for electrical wiring (*first revision*)
IS 3854 : 2023	Specification for switches for domestic and similar purposes (*third revision*)
IS 4159 : 2021	Mineral filled sheathed heating elements (*fourth revision*)
IS 4160 : 2005	Specification for interlocking switch socket outlets (*first revision*)
IS 4649 : 1968	Specification for adaptors for flexible steel conduits
IS 9385 (Part 1) : 2024/ IEC 60282-1 : 2020	High -voltage fuses: Part 1 Current-limiting fuses (*second revision*)
IS 9385 (Part 2) : 2018	High-voltage fuses: Part 2 Expulsion fuses (*first revision*)
IS 9385 (Part 6) : 2025/ IEC 60282-4 : 2020	High-voltage fuses: Part 6 Additional testing requirements for high-voltage expulsion fuses utilizing polymeric insulators
IS 9537	Specification for conduits for electrical installations:
(Part 1) : 1980	General requirements
(Part 2) : 1981	Rigid steel conduits
(Part 3) : 1983	Rigid plain conduits for insulating materials
(Part 4) : 1983	Pliable self-recovering conduits for insulating materials
(Part 5) : 2000	Pliable conduits of insulating materials
(Part 6) : 2000	Pliable conduits of metal or composite materials
(Part 8) : 2003	Rigid non threadable conduits of aluminium alloy
IS 9926 : 1981	Specification for fuse wires used in rewirable type electric fuses up to 650 volts

IS No.	*Title*
IS 10027 : 2018	Composite units of air-break switches and rewirable type fuses for voltages not exceeding 650 V a.c. — Specification (*second revision*)
IS 10322	Specification for luminaires:
(Part 1) : 2014	General requirements and tests (*first revision*)
(Part 5)	Particular requirements,
(Sec 1) : 2012	General purpose luminaires (*first revision*)
(Sec 2) : 2012	Recessed luminaires (*first revision*)
(Sec 3) : 2012	Luminaires for road and street lighting (*first revision*)
(Sec 4) : 1987	Portable general purpose luminaires
(Sec 5) : 2013	Flood light (*first revision*)
(Sec 6) : 2013	Hand lamps
(Sec 7) : 2017/ IEC 60598- 2-20 : 2014	Lighting chains (*first revision*)
(Sec 8) : 2013	Emergency lighting
(Sec 9) : 2017/ IEC 60598-2-21 : 2014	Rope lights
IS 11037 : 2019	Electronic type fan regulators specification (*first revision*)
IS 12640	Residual current operated circuit-breakers without integral overcurrent protection for household and similar uses (RCCBs):
(Part 1) : 2024/ IEC 61008-1 : 2013	General rules (*third revision*)
(Part 2) : 2016/ IEC 61009-1 : 2012	General rules (*second revision*)
(Part 3) : 2018/ IEC 1008-2-1 : 1990	Applicability of the general rule to RCCB's functionally independent of line voltage
(Part 4) : 2018/ IEC 61008-2-2 : 1990	Applicability of the general rules to RCCB's functionally dependent on line voltage
IS 12776 : 2002	Specification for galvanized strand for earthing (*first revision*)
IS 13010 : 2002	AC watt-hour meters, Class 0.5, 1 and 2 (*first revision*)
IS 13779 : 2020	a.c. static watthour meters class 1 and 2-Specefication (*second revision*)
IS 13947 (Part 5/Sec 2) : 2004/ IEC 60947-5-2(1999)	Low-voltage switchgear and controlgear — Specification: Part 5 Control circuit devices and switching elements, Section 2 Proximity switches
IS 14614 : 2023	Residual current — operated protective devices (RCDs) for household and similar use — Electromagnetic compatibility (*first revision*)

IS No.	*Title*
IS 14697 : 2021	a.c. Static transformer operated watthour meters (Class 0.2 S and 0.5 S) and Var-hour meters (Class 0.2 S, 0.5 S and 1 S) — Specification (*first revision*)
IS 14763 : 2022	Conduit systems for cable management outside diameters of conduits for electrical installations and threads for conduits and fittings (*first revision*)
IS 14768	Conduit fittings for electrical installations:
(Part 1) : 2000	General requirements
(Part 2) : 2003	Metal conduit fittings
IS 14772 : 2020	Boxes and enclosures for electrical accessories for household and similar fixed electrical installations general requirements (*first revision*)
IS 14897 : 2021	Glass bulb designation system for lamps (*first revision*)
IS 14927	Cable trunking systems and cable ducting systems for electrical installations:
(Part 1) : 2023	General requirements (*first revision*)
(Part 2/Sec 1) : 2023/ IEC 61084-2-1 : 2017	Cable trunking systems and cable ducting systems intended for mounting on walls and ceilings, Section 1 Particular requirements (*first revision*)
IS 15111	Self-Ballasted lamps for general lighting services:
(Part 1) : 2002	Safety requirements
(Part 2) : 2002	Performance requirements
IS 15368 : 2003	Cable reels for household and similar purposes
IS 15518 (Part 1) : 2004	Safety requirements for incandescent lamps: Part 1 Tungsten filament lamps for domestic and similar general lighting purposes
IS 15787 : 2025	Switched socket-outlets without interlock for fixed installations — Particular requirements (*first revision*)
IS 15968 : 2013	Ballasts for tubular fluorescent lamps — Performance requirements
IS 15974 : 2013	Auxiliaries for lamps — Starting devices (other than glow starters) — Performance requirements
IS 16102	Self-ballasted LED-lamps for general lighting services:
(Part 1) : 2026	Safety requirements (*first revision*)
(Part 2) : 2026	Performance requirements (*second revision*)
IS 16103	LED modules for general lighting:
(Part 1) : 2025/ IEC 62031 : 2018	Safety — Specifications (*first revision*)
(Part 2) : 2025/ IEC 62717 : 2019 CSV	Performance requirements (*first revision*)
IS 16148 : 2014/ IEC 61167 : 2011	Metal halide lamps — Performance specification

IS No.	*Title*
IS 16444 (Part 2) : 2017	a.c. Static transformer operated watthour and var-hour smart meters, class 0.2 s, 0.5 s and 1.0 s: Part 2 Specification transformer operated smart meters
IS 16463 (Part 12) : 2026/ IEC 61643-12 : 2020	Low-voltage surge protective devices: Part 12 Surge protective devices connected to low-voltage power distribution systems — Selection and application principles (*first revision*)
IS 16614	Double-capped LED linear lamps:
(Part 1) : 2026	Safety requirements (*first revision*)
(Part 2) : 2022	Performance requirements
IS 17119 : 2019	Residual current devices with or without overcurrent protection for socket-outlets for household and similar uses
IS 17121 : 2019/IEC 62606 : 2017	General requirements for arc fault detection devices
IS 17122 : 2019	Electrical accessories — Circuit-Breakers and similar equipment for household use — Auxiliary contact units
IS 17345	Power track system:
(Part 1) : 2020	General requirement
(Part 21) : 2020	Particular requirements for power track systems intended for wall and ceiling mounting
IS 18751 : 2024	Polymer coated inner tanks for storage water heater — Specification
IS 18830 : 2024	Cord extension sets — Specifications
IS/IEC 60079	Explosive atmospheres:
(Part 0) : 2017	General requirements (*third revision*)
(Part 1) : 2014	Equipment protection by flameproof enclosures “d” (*first revision*)
(Part 7) : 2017	Equipment protection by increased safety “e” (*second revision*)
(Part 13) : 2017	Equipment protection by pressurized room “p” and artificially ventilated room “v” (*first revision*)
(Part 15) : 2017	Equipment protection by type of protection “n” (*second revision*)
(Part 19) : 2019	Equipment repair overhaul and reclamation (*second revision*)
(Part 25) : 2020	Intrinsically safe electrical systems (*second revision*)
(Part 26) : 2021	Equipment with separation elements or combined levels of protection (*second revision*)
(Part 31) : 2022	Equipment dust ignition protection by enclosure “t” (*second revision*)
(Part 39) : 2015	Intrinsically safe systems with electronically controlled spark duration limitation

IS No.	*Title*
(Part 42) : 2019	Electrical safety devices for the control of potential ignition sources from ex-equipment
(Part 43) : 2017	Equipment in adverse service conditions
(Part 46) : 2017	Equipment assemblies
(Part 47) : 2021	Equipment Protection by 2-wire intrinsically safe ethernet concept (2-WISE)
IS/IEC 60127	Miniature fuses:
(Part 3) : 2015	Sub-miniature fuse-links
(Part 10) : 2001	User guide for miniature fuses
IS/IEC 60309	Plugs fixed or portable socket-outlets and appliance inlets for industrial purposes
(Part 1) : 2021	General requirements (*second revision*)
(Part 2) : 2021	Dimensional compatibility requirements for pin and contact-tube accessories (*second revision*)
IS/IEC 60320	Appliance couplers for household and similar general purposes
(Part 1) : 2021	General requirements (*first revision*)
(Part 2/Sec 3) : 2018	Particular requirement, Section 3 Appliance couplers with a degree of protection higher than IPX0 (*first revision*)
IS/IEC 60669 (Part 2/Sec 1) : 2021	Switches for household and similar fixed electrical installations: Part 2-1: Particular requirements electronic control devices (*first revision*)
IS/IEC 60794	Optical fibre cables:
(Part 1)	Generic specification,
(Sec 1) : 2015	General (*first revision*)
(Sec 2) : 2017	Basic optical cable test procedures — General guidance (*first revision*)
(Part 2) : 2017	Indoor cables, Sectional specification (*first revision*)
(Part 2/Sec 11) : 2020	Indoor cables, Section 11 Detailed specification for simplex and duplex cables for use in premises cabling (*first revision*)
(Part 4/Sec 20) : 2018	Sectional specification, Section 20 Aerial optical cables along electrical power lines family specification for ADSS all dielectric self-supported optical cables
IS/IEC 60898	Electrical accessories — Circuit-breakers for overcurrent protection for household and similar installations
(Part 1) : 2015	Circuit-breakers for a.c. operation (*first revision*)
(Part 2) : 2016	Circuit-breakers for a.c. and d.c. operation (*first revision*)
(Part 3) : 2019	Circuit-breakers for d.c. operation
IS/IEC 60947	Low-voltage switchgear and controlgear:

IS No.	*Title*
(Part 1) : 2020	General rules (*second revision*)
(Part 2) : 2016	Circuit-breakers (*first revision*)
(Part 3) : 2020	Switches, disconnectors, switch-disconnectors and fuse-combination units (*first revision*)
(Part 4)	Contactors and motor-starters,
(Sec 1) : 2023	Electromechanical contactors and motor-starters (*third revision*)
(Sec 2) : 2020	Semiconductor motor controllers, starters and soft-starters (*second revision*)
(Sec 3) : 2020	Semiconductor controllers and semiconductor contactors for non-motor loads *(third revision*)
(Part 5)	Control circuit devices and switching elements,
(Sec 1) : 2024	Electromechanical control circuit devices (*third revision*)
(Sec 2) : 2019	Proximity switches (*first revision*)
(Sec 5) : 2016	Electrical emergency stop devices with mechanical latching function
(Part 6)	Multiple function equipment,
(Sec 1) : 2021	Transfer switching equipment (*first revision*)
(Sec 2) : 2020	Control and protective switching devices or equipment (CPS) (*first revision*)
(Part 7)	Ancillary equipment,
(Sec 1) : 2009	Terminal blocks for copper conductors
(Sec 2) : 2009	Protective conductor terminal blocks for copper conductors
IS/IEC 61058	Switches for appliances:
(Part 1)	Particular requirements,
(Sec 1) : 2016	Mechanical switches
(Sec 2) : 2016	Particular requirements for electronics switches
IS/IEC 61439	Low-voltage switchgear and controlgear assemblies:

IS/IEC 61757 : 2018	Fibre optic sensors — Generic specification
IS/IEC/TR 62655 : 2013	Tutorial and application guide for high-voltage fuses
IS/IEC 63008 : 2020	Household and similar electrical appliances accessibility of control elements, doors, lids, drawers and handles

IS No.	*Title*
IS/ISO/IEC 80079	Explosive atmospheres:
(Part 20)	Material characteristics for gas and vapour classification,
(Sec 1) : 2017	Test methods and data
(Sec 2) : 2016	Combustible dusts test methods
(Part 36) : 2016	Non-electrical equipment for explosive atmospheres — Basic method and requirements
(Part 37) : 2016	Non-electrical equipment for explosive atmospheres — Non electrical type of protection constructional safety “c”, control of ignition source “b”, liquid immersion “k”

13 FILLERS, STOPPERS AND PUTTIES

IS No.	*Title*
IS 110 : 2017	Ready mixed paint brushing grey filler for enamels for use over primers — Specification (*third revision*)
IS 419 : 1967	Specification for putty for use on window frames (*first revision*)
IS 419 : 2023	Putty for use on window frames — Specification (*second revision*)
IS 423 : 1961	Specification for plastic wood, for joiner’s filler (*revised*)
IS 3709 : 1966	Specification for mastic cement for bedding of metal windows
IS 7164 : 1973	Specification for stopper
IS 13184 : 1991	Specification for mastic filler, epoxy based

14 FLOOR COVERING, ROOFING AND OTHER FINISHES

a) Concrete Flooring

IS No.	*Title*
IS 1237 : 2012	Specification for cement concrete flooring tiles (*second revision*)
IS 6073 : 2006	Autoclaved reinforced cellular concrete floor and roof slabs — Specification (*first revision*)
IS 13801 : 2013	Chequered cement concrete tiles — Specification (*first revision*)
IS 13990 : 1994	Specification for precast reinforced concrete planks and joists for flooring and roofing
IS 14201 : 1994	Precast reinforced concrete channel units for construction of floors and roofs — Specification
IS 15658 : 2021	Concrete paving blocks — Specification (*first revision*)

b) Flooring Compositions

IS No.	*Title*
IS 657 : 1982	Specification for materials for use in the manufacture of magnesium oxychloride flooring compositions (*second revision*)
IS 9162 : 1979	Methods of tests for epoxy resin, hardeners and epoxy resin composition for floor topping
IS 9197 : 1979	Specification for epoxy resin, hardness and epoxy resin compositions for floor topping
IS 10132 : 1982	Method of test for materials for use in the preparation of magnesium oxychloride flooring composition

c) Linoleum Flooring

IS No.	*Title*
IS 653 : 1992	Specification for linoleum sheets and tiles (*third revision*)
IS 9704 : 1980	Methods of tests for linoleum sheets and tiles

d) Rubber Flooring

IS No.	*Title*
IS 809 : 1992	Specification for rubber flooring materials for general purposes (*second revision*)

e) Stone Flooring

IS No.	*Title*
IS 1128 : 1974	Specification for limestone (slab and tiles) (*first revision*)
IS 1130 : 1969	Specification for marble (blocks, slabs and tiles)
IS 3316 : 1974	Specification for structural granite (*first revision*)
IS 3622 : 1977	Specification for sand stone (slabs and tiles) (*first revision*)
IS 14223 (Part 1) : 2023	Polished building stones specification: Part 1 Granite and similar stones (*first revision*)

f) Bituminous Flooring

IS No.	*Title*
IS 1195 : 2002	Specification for bitumen mastic for flooring (*third revision*)
IS 5317 : 2002	Specification for pitch-mastic for bridge decking and roads (*second revision*)
IS 8374 : 1977	Specification for bitumen mastic, anti-static and electrically conducting grade
IS 9510 : 1980	Specification for bitumen mastic acid resisting grade
IS 13026 : 1991	Specification for bitumen mastic for flooring for industries handling LPG and other light hydrocarbon products

IS 15194 : 2002	Specification for pitch-mastic flooring for industries handling heavy hydrocarbon products like kerosene, diesel and furnace oil

g) Plastic Flooring

IS No.	*Title*
IS 3461 : 1980	Specification for PVC asbestos floor tiles (*first revision*)
IS 3462 : 1986	Specification for unbacked flexible PVC flooring (*second revision*)
IS 3464 : 1986	Methods of test for plastic flooring and wall tiles (*second revision*)

h) Ceramic/Vitreous Flooring and Wall Finishing

IS No.	*Title*
IS 2333 : 2025	Plaster of Paris for ceramic and glass industry — Specification (*third revision*)
IS 4457 : 2007	Ceramic unglazed vitreous acid resisting tile — Specification (*second revision*)
IS 13630	Ceramic tiles methods of test sampling and basis for acceptance:
(Part 1) : 2019	Determination of dimensions and surface quality (*second revision*)
(Part 2) : 2019	Determination of water absorption and bulk density (*second revision*)
(Part 3) : 2019	Determination of moisture expansion using boiling water (*second revision*)
(Part 4) : 2019	Determination of linear thermal expansion (*second revision*)
(Part 5) : 2019	Determination of resistance to thermal shock (*second revision*)
(Part 6) : 2019	Determination of modulus of rupture and breaking strength (*second revision*)
(Part 7) : 2019	Determination of stain and chemical resistance of unglazed tiles (s*econd revision*)
(Part 8) : 2019	Determination of stain and chemical resistance of glazed tiles (*second revision*)
(Part 9) : 2019	Determination of crazing resistance of glazed tiles (*second revision*)
(Part 10) : 2019	Determination of frost resistance (*second revision*)
(Part 11) : 2019	Determination of resistance to surface abrasion of glazed tiles (*second revision*)
(Part 12) : 2019	Determination of resistance to deep abrasion of unglazed tiles (*second revision*)
(Part 13) : 2019	Determination of scratch hardness of surface according to Mohs scale (*second revision*)
(Part 14) : 2019	Determination of impact resistance by measurement of coefficient of restitution (*first revision*)
(Part 15) : 2019	Sampling and basis for acceptance (*first revision*)
(Part 16) : 2019	Determination of lead and cadmium given off by glazed tiles

IS No.	*Title*
IS 13712 : 2019	Ceramic tiles definitions classifications characteristics and marking (*second revision*)
IS 15622 : 2017	Pressed ceramic tiles — Specification (*first revision*)
IS 17933 : 2022	Fine ceramics (advanced ceramics, advanced technical ceramics) — Test method for flexural strength of monolithic ceramics at room temperature
IS 17935 : 2022	Fine ceramics (advanced ceramics, advanced technical ceramics) — Determination of density and apparent porosity
IS 17975 : 2022	Fine ceramics (advanced ceramics, advanced technical ceramics) — test method for fracture resistance of silicon nitride materials for rolling bearing balls at room temperature by indentation fracture (IF) method
IS 17981 : 2022	Fine ceramics (advanced ceramics, advanced technical ceramics) — Test method for elastic moduli of monolithic ceramics at room temperature by sonic resonance
IS 17991 : 2022	Fine ceramics (advanced ceramics, advanced technical ceramics) — Test method for hardness of monolithic ceramics at room temperature
IS 18221 : 2023	Fine ceramics (Advanced ceramics, advanced technical ceramics) — Test method for linear thermal expansion of monolithic ceramics by push-rod technique

j) Clay Flooring

IS No.	*Title*
IS 1478 : 2023	Clay flooring tiles specification (*third revision*)
IS 3951	Hollow clay tiles for floors and roofs specification:
(Part 1) : 2023	Filler type (*third revision*)
(Part 2) : 2023	Structural type (*third revision*)

k) Roofing

IS No.	*Title*
IS 277 : 2018	Galvanized steel strips and sheets plain and corrugated — Specification (*seventh revision*)
IS 459 : 1992	Specification for corrugated and semi-corrugated asbestos cement sheets (*third revision*)
IS 654 : 2023	Clay roofing tiles mangalore pattern specification (*fourth revision*)
IS 1464 : 2024	Clay ridge and ceiling tiles — Specification (*third revision*)
IS 2690	Burnt clay flat terracing tiles — Specification:
(Part 1) : 2023	Machine made (*third revision*)
(Part 2) : 2023	Handmade (*third revision*)

IS No.	*Title*
IS 3951	Hollow clay tiles for floors and roofs specification:
(Part 1) : 2023	Filler type (*third revision*)
(Part 2) : 2023	Structural type (*third revision*)
IS 6073 : 2006	Autoclaved reinforced cellular concrete floor and roof slabs (*first revision*)
IS 6250 : 1981	Specification for roofing slate tiles (*first revision*)
IS 10388 : 1982	Specification for corrugated coir wood wool cement roofing sheets
IS 12583 : 1988	Specification for corrugated bitumen roofing sheets
IS 12866 : 2021	Plastic translucent sheets made from thermo-setting polyester resin (glass fibre reinforced) — Specification (*first revision*)
IS 13317 : 2023	Clay roofing country tiles half round and flat tiles Specification (*first revision*)
IS 13990 : 1994	Specification for precast reinforced concrete planks and joists for flooring and roofing
IS 14201 : 1994	Precast reinforced concrete channel units for construction of floors and roofs — Specification
IS 14241 : 1995	Specification for precast L-Panel units for roofing
IS 14246 : 2024	Continuously pre-painted galvanized steel sheets and strips — Specification (*second revision*)
IS 15965 : 2012	Pre-Painted aluminium zinc alloy metallic coated steel strip and sheet (plain)
IS 18385 : 2023	Hot-Dip galvanized/galvannealed steel sheet, plate and strip for automotive applications — Specification

m) Other Floorings and Roofings

IS No.	*Title*
IS 4456	Methods of test for chemical resistant mortars:
(Part 1) : 2026	Silicate type and resin type (*first revision*)
(Part 2) : 2026	Sulphur type (*first revision*)
IS 4457 : 2007	Ceramic unglazed vitreous acid resisting tile — Specification (*second revision*)
IS 4832	Chemical resistant mortars specification:
(Part 1) : 2023	Silicate type (*first revision*)
(Part 2) : 2023	Resin type (*first revision*)
(Part 3) : 2023	Sulphur type (*first revision*)
IS 4860 : 1968	Specification for acid resistant bricks

IS No.	*Title*
IS 14862 : 2000	Specification for fibre cement flat sheets
IS 14143 : 1994	Specification for prefabricated brick panel and partially precast concrete joist for flooring and roofing
IS 14871 : 2000	Products in fibre reinforced cement — Long corrugated or asymmetrical section sheets and fittings for roofing and cladding — Specification
IS 18433	Measurement of surface frictional properties — Methods of test:
(Part 1) : 2023	Pendulum test
(Part 2) : 2023	Ramp test

n) Wall Coverings/Finishing

IS No.	*Title*
IS 1542 : 1992	Specification for sand for plaster (*second revision*)
IS 3952 : 2013	Burnt clay hollow bricks and blocks for walls and partitions — Specification (*third revision*)
IS 4456	Methods of test for chemical resistant mortars:
(Part 1) : 1967	Silicate type and resin type
(Part 2) : 1967	Sulphur type
IS 4832	Chemical resistant mortars specification:
(Part 1) : 2023	Silicate type (*first revision*)
(Part 2) : 2023	Resin type (*first revision*)
(Part 3) : 2023	Sulphur type (*first revision*)
IS 15418 : 2003	Wall coverings in roll form for finished wall papers, wall vinyls and plastic wall coverings — Specification

15 GLASS

IS No.	*Title*
IS 2553 (Part 1) : 2018	Safety glass — Specification: Part 1 Architectural building and general uses (*fourth revision*)
IS 2835 : 1987	Specification for flat transparent sheet glass (*third revision*)
IS 3438 : 2023	Silvered glass mirrors for general purposes specification (*third revision*)
IS 5437 : 2024	Rolled glass patterned extra clear patterned wired and wired-patterned glass specification (*second revision*)
IS 9154 : 2020	Method for determination of alkali resistance of glass (*first revision*)
IS 12869	Methods for determination of viscosity and viscometric fixed points of glass:
(Part 1) : 2022	Standard test methods (*first revision*)

IS No.	*Title*
(Part 2) : 2022	Determination of softening point (*first revision*)
IS 14900 : 2018	Transparent float glass — Specification (*first revision*)
IS 16526 : 2017	Atactic polypropylene (APP) modified bituminous waterproofing and damp-proofing membrane with glass fibre reinforcement — Specification
IS 16945 : 2018	Fire resistance test for glass walls
IS 16947 : 2018	Fire resistance tests for doors with glass panes, openable glass windows and sliding glass doors
IS 16978	Glass in building — Forced-entry security glazing:
(Part 1) : 2022	Test and classification by repetitive ball drop (*first revision*)
(Part 2) : 2018	Test and classification by repetitive impact of a hammer and axe at room temperature
(Part 3) : 2018	Test and classification by manual attack
(Part 4) : 2018	Test and classification by pendulum impact under thermally and fire stressed conditions
IS 16982 : 2018	Heat strengthened glass — Specification
IS 17004 : 2018	Testing methods for processed glass
IS 17346 : 2020	Insulating glazing unit — Specification
IS 18222 : 2023	Glass-Resistance to attack by hydrochloric acid at 100 °C — Flame emission or flame atomic absorption spectrometric method
IS 18518 : 2023	Bullet resistant security glass — Quality and performance requirements
IS 19328 : 2025	Fire resistant glass — Specification
IS 19331 : 2025	Tinted float glass — Specification

16 GYPSUM BASED MATERIALS

IS No.	*Title*
IS 2095	Specification for gypsum plaster boards:
(Part 1) : 2023	Plain gypsum plaster boards (*fourth revision*)
(Part 2) : 2022	Coated laminated gypsum plaster boards (*third revision*)
(Part 3) : 2022	Reinforced gypsum plaster boards tiles cornices and mouldings (*third revision*)
IS 2542	Gypsum plaster concrete and products methods of test:
(Part 1)	Plaster and concrete,
(Sec 1) : 2023	Determination of normal consistency of gypsum plaster (*second revision*)

IS No.	*Title*
(Sec 2) : 2023	Determination of normal consistency of gypsum concrete (*second revision*)
(Sec 3) : 2023	Determination of setting time of plaster and concrete (*second revision*)
(Sec 4) : 2023	Determination of transverse strength of gypsum plaster (*second revision*)
(Sec 5) : 2023	Determination of compressive strength and dry set density of gypsum plaster (*second revision*)
(Sec 6) : 2023	Determination of soundness of gypsum plaster (*second revision*)
(Sec 7) : 2023	Determination of impact resistance of gypsum plaster by dropping ball test (*second revision*)
(Sec 8) : 2023	Determination of mass of coarse particles (*second revision*)
(Sec 9) : 2023	Determination of expansion of gypsum plaster (*second revision*)
(Sec 10) : 2023	Determination of sand in set gypsum plaster (*second revision*)
(Sec 11) : 2023	Determination of wood fibre content in wood fibre gypsum plaster (*second revision*)
(Sec 12) : 2023	Determination of dry bulk density (*second revision*)
(Sec 13) : 2023	Determination of free water (*second revision*)
(Sec 14) : 2023	Determination of fineness (*second revision*)
(Part 2)	Gypsum products,
(Sec 1) : 1981	Measurement of dimensions (*first revision*)
(Sec 2) : 1981	Determination of mass (*first revision*)
(Sec 3) : 1981	Determination of mass and thickness of paper surfacing (*first revision*)
(Sec 4) : 1981	Transverse strength (*first revision*)
(Sec 5) : 1981	Compressive strength (*first revision*)
(Sec 6) : 1981	Gypsum products, Section 6 Water absorption (*first revision*)
(Sec 7) : 1981	Moisture content (*first revision*)
(Sec 8) : 1981	Nail retention of precast reinforced gypsum slabs (*first revision*)
IS 2547	Specification for gypsum building plaster:
(Part 1) : 1976	Excluding premixed lightweight plaster (*first revision*)
(Part 2) : 1976	Premixed lightweight plaster (*first revision*)
IS 2849 : 1983	Specification for non-load bearing gypsum partition blocks (solid and hollow types) (*first revision*)
IS 8272 : 1984	Specification for gypsum plaster for use in the manufacture of fibrous plasterboards (*first revision*)

IS No.	*Title*
IS 9498 : 1980	Specification for inorganic aggregates for use in gypsum plaster
IS 12679 : 2023	By-Product gypsum for construction — Specification (*second revision*)
IS 17400 : 2021	Glass fibre reinforced gypsum building panels – Specification
IS 18387 : 2023	Gypsum ceiling tiles — Specification

17 MORTAR (Including Sand for Mortar)

IS No.	*Title*
IS 2116 : 1980	Sand for masonry mortars — Specification (*first revision*)
IS 2250 : 1981	Code of practice for preparation and use of masonry mortars (*first revision*)
IS 3085 : 1965	Method of test for permeability of cement mortar and concrete
IS 4098 : 1983	Specification for lime-pozzolana mixture (*first revision*)
IS 4456	Methods of test for chemical resistant mortars:
(Part 1) : 1967	Silicate type and resin type
(Part 2) : 1967	Sulphur type
IS 4832	Chemical resistant mortars specification:
(Part 1) : 2023	Silicate type (*first revision*)
(Part 2) : 2023	Resin type (*first revision*)
(Part 3) : 2023	Sulphur type (*first revision*)
IS 13077 : 1991	Guide for preparation and use of mud mortar in masonry
IS 14959	Method of test determination of water soluble and acid soluble chlorides in mortar and concrete
(Part 1) : 2001	Fresh mortar and concrete
(Part 2) : 2001	Hardened mortar and concrete

18 PAINTS AND ALLIED PRODUCTS

a) Water Based Paints and Pigments

IS No.	*Title*
IS 427 : 2013	Distemper, dry, colour as required — Specification (*third revision*)
IS 428 : 2013	Washable distemper — Specification (*third revision*)
IS 5410 : 2013	Specification for cement paint (*second revision*)
IS 15489 : 2024	Paint, plastic emulsion — Specification (*second revision*)

b) Ready Mixed Paints, Enamels and Powder Coatings

IS No.	*Title*
IS 101	Methods of sampling and test for paints, varnishes and related products:
(Part 1)	Tests on liquid paints general and physical,
(Sec 1) : 2023	Sampling (*fourth revision*)
(Sec 2) : 2023/ ISO 1513 : 2010	Preliminary examination and preparation of samples for testing (*fourth revision*)
(Sec 3) : 1986	Preparation of panels (*third revision*)
(Sec 4) : 2024	Brushing test (*fourth revision*)
(Sec 5) : 2024	Consistency (*fourth revision*)
(Sec 5) : 2024	Consistency (*fourth revision*)
(Sec 6) : 1987	Flash point (*third revision*)
(Sec 7) : 2020/ ISO 2811-1	Mass per 10 litres determination of density pycnometer method (*fourth revision*)
(Sec 8) : 2022/ ISO 787-9 : 2019	Pigments and extenders determination of *p*H value of an aqueous suspension (*first revision*)
(Part 2)	Test on liquid paints chemical examination,
(Sec 1) : 2018	Water content (*fourth revision*)
(Sec 2) : 2025	Determination of non-volatile matter content (*fourth revision*)
(Sec 3) : 2015/ ISO 11890-1	Determination of volatile organic compound VOC content — Difference method
(Sec 4) : 2022/ ISO 11890-2 : 2020	Determination of volatile organic compound VOC and or semi volatile organic compounds SVOC content gas-chromatographic (*first revision*)
(Sec 5) : 2017/ ISO 17895 : 2005	Determination of volatile organic compound content of low-VOC emulsion paints (In-Can VOC)
(Part 3)	Tests on paint film formation,
(Sec 1) : 1986	Drying time (*third revision*)
(Sec 2) : 2025/ ISO 2808 : 2019	Determination of film thickness (*fourth revision*)
(Sec 4) : 1987	Finish (*third revision*)
(Sec 5) : 2022/ ISO 1524 : 2020	Determination of fineness of grind (*fifth revision*)
(Sec 6) : 2024/ ISO 19403-3 : 2017	Determination of the surface tension of liquid using the pendant drop method
(Part 4)	Optical test,

IS No.	*Title*
(Sec 1) : 1988	Opacity (*third revision*)
(Sec 2) : 2021/ ISO 3668 : 2017	Colour-visual comparison of colour of paints (*fourth revision*)
(Sec 3) : 1988	Light fastness test (*third revision*)
(Sec 4) : 2020/ ISO 2813 : 2014	Gloss determination of gloss value at 20°, 60° and 85° (*fourth revision*)
(Part 5)	Mechanical test on paint films,
(Sec 1) : 1988	Hardness tests (*third revision*)
(Sec 2) :1988	Flexibility and adhesion (*third revision*)
(Sec 3) : 2019/ ISO 6272-1 : 2011	Impact resistance — Falling-weight test large-area indenter (*fifth revision*)
(Sec 4) : 1988	Print free test (*third revision*)
(Sec 5) : 2019/ ISO 6272-2 : 2011	Impact resistance — Falling-weight test small-area indenter
(Sec 6) : 2024/ ISO 7784-1 : 2023	Determination of resistance to abrasion by abrasive-paper covered wheels and rotating test specimen
(Sec 7) : 2024/ ISO 7784-2 : 2023	Determination of resistance to abrasion by abrasive rubber wheels and rotating test specimen
(Part 6)	Durability tests,
(Sec 1) : 1988	Resistance to humidity under conditions of condensation (*third revision*)
(Sec 2) : 1989	Keeping properties (*third revision*)
(Sec 3) : 1990	Moisture vapour permeability (*third revision*)
(Sec 4) : 1991	Degradation of coatings (pictorial aids for evaluation)
(Sec 5) : 1997	Accelerated weathering test (*third revision*)
(Part 7)	Environmental tests on paint films,
(Sec 1) : 1989	Resistance to water (*third revision*)
(Sec 2) : 1990	Resistance to liquids (*third revision*)
(Sec 3) : 2020/ ISO 3248 : 2016	Determination of the effect of heat (*fourth revision*)
(Sec 4) : 1990	Resistance to bleeding of pigments (*third revision*)
(Part 8)	Tests for pigments and other solids,
(Sec 1) : 1989	Residue on sieve (*third revision*)
(Sec 2) : 1990	Pigments and non –volatile matter (*third revision*)

IS No.	*Title*
(Sec 3):1993	Ash content (*third revision*)
(Sec 4) : 2015	Phthalic anhydride (*fourth revision*)
(Sec 5) : 2022	Lead restriction test (*fourth revision*)
(Sec 6) : 1993	Volume solids
(Part 9)	Tests for lacquers and varnish,
(Sec 1) : 1993	Acid value (*third revision*)
(Sec 2) : 1993	Rosin test (*third revision*)
(Part 10)	Instrumental analysis,
(Sec 1) : 2022/ ISO 13320 : 2020	Particle size analysis — Laser diffraction methods (*first revision*)
(Sec 2) : 2018/ ISO 16773-1 : 2016	Electrochemical impedance spectroscopy EIS on coated and uncoated metallic specimens — Terms and definitions
(Sec 3) : 2018/ ISO 16773-2 : 2016	Electrochemical impedance spectroscopy EIS on coated and uncoated metallic specimens — Collection of data
(Sec 4) : 2018/ ISO 16773-3 : 2016	Electrochemical impedance spectroscopy EIS on coated and uncoated metallic specimens — Processing and analysis of data from dummy cells
(Sec 5) : 2018/ ISO 16773-4	Electrochemical impedance spectroscopy EIS on coated and uncoated metallic specimens — Examples of spectra of polymer — Coated and uncoated specimens
(Part 11)	Evaluation of degradation of coatings — Designation of quantity and size of defects and of intensity of uniform changes in appearance,
(Sec 2) : 2024/ ISO 4628-2 : 2016	Assessment of degree of blistering
(Sec 5) : 2024/ ISO 4628-5 : 2022	Assessment of degree of flaking
IS 104 : 2017	Specification for ready mixed paint brushing zinc chrome priming (*third revision*)
IS 109 : 2017	Specification for ready mixed paint finishing priming plaster to Indian Standard colour no 361 light stone and no 631 light grey white and off — white (*second revision*)
IS 137 : 2017	Ready mixed paint brushing matt or eggshell flat finishing interior to Indian standard colour as required — Specification (*second revision*)
IS 151 : 2017	Ready mixed paint, spraying, finishing, stoving, enamel for general purposes, colour as required — Specification (*second revision*)
IS 158 : 2015	Ready mixed paint brushing bituminous black acid alkali and heat resisting — Specification (*fourth revision*)
IS 159 : 2024	Ready mixed paint, brushing, acid resisting — Specification (*second revision*)
IS 164 : 2023	Ready mixed paint for road marking — Specification (*third revision*)

IS No.	*Title*
IS 168 : 2024	Ready mixed paint air drying for general purpose — Specification (*fifth revision*)
IS 341 : 2016	Black japan, types A, B and C — Specification (*second revision*)
IS 486 : 2023	Brushes, sash tool for paints and varnishes — Specification (*fifth revision*)
IS 2074 : 2023	Ready mixed paint air drying red oxide zinc chrome priming — Specification (*fourth revision*)
IS 2075 : 2017	Ready mixed paint stoving red oxide zinc chrome priming — Specification (*third revision*)
IS 2339 : 2013	Specification for aluminium paint for general purposes (*first revision*)
IS 2932 : 2025	Air drying enamel paint for architectural and industrial applications — Specification (*fifth revision*)
IS 3536 : 2016	Ready mixed paint, brushing, wood primer — Specification (*second revision*)
IS 3537 : 2017	Ready mixed paint, finishing, interior, for general purposes, to Indian Standard colours — Specification (*first revision*)
IS 3539 : 1966	Specification for ready mixed paint, undercoating, for use under oil finishes, to Indian Standard colours, as required
IS 3585 : 2018	Ready mixed paint, aluminium, brushing, priming, water resistant for woodwork — Specification (*first revision*)
IS 3678 : 2016	Ready mixed paint, thick white, for lettering — Specification (*first revision*)
IS 8687	Vitreous enamels and frits — Method of test:
(Part 1) : 2023	Sieve analysis (*first revision*)
(Part 2) : 2020	Fusion flow test (*first revision*)
IS 8709 : 2023	Colour retention of vitreous enamel coatings — Method of test (*first revision*)
IS 8767 : 2020	Calcium carbonate, precipitated, and activated, for paints —Specification (*first revision*)
IS 9862 : 2017	Specification for ready mixed paint brushing bituminous black acid alkali water and chlorine resisting (*first revision*)
IS 11883 : 2017	Ready mixed paint, brushing, red oxide, priming for metals – Specification (*first revision*)
IS 12744 (Part 1) : 2013	Ready mixed paint, air drying, red oxide — Zinc phosphate, priming – Specification: Part 1 For domestic and decorative applications (*fourth revision*)
IS 13183 : 1991	Specification for aluminium paints, heat resistant
IS 13213 : 2018	Polyurethane full gloss enamel (two pack) — Specification (*first revision*)
IS 13607 : 1992	Specification for ready mixed paint, finishing, general purposes, synthetic
IS 13871 : 2021	Powder coating — Specification (*first revision*)
IS 14506 : 1998	Epoxy redoxide zinc phosphate weldable primer, two component — Specification

IS No.	*Title*
IS 14589 : 1999	Zinc priming paint, epoxy based, two pack — Specification
IS 16719 : 2022	Solvent free polyurethane coatings for exterior of steel pipe and fittings — Specification (*first revision*)
IS 16942 : 2018	Silicone soya alkyd exterior paint — Specification
IS 17044 : 2018	Intumescent fire retardant paint (water based) — Specification
IS 17680 (Part 1) : 2021/ ISO 18314-1 : 2015	Analytical colorimetry: Part 1 Practical colour measurement
IS 18563 : 2024	Nanomodified paints and coatings — Code of practice
IS 19003 : 2022	Re-dispersible polymer powder — Specification

c) Thinners and Solvents

IS No.	*Title*
IS 82:1973	Methods of sampling and test for thinners and solvents for paints (*first revision*)
IS 384	Flat brushes for paints and varnishes — Specification:
(Part 1) : 2023	Heavy duty (*seventh revision*)
(Part 2) : 2023	Household purposes *(seventh revision)*
IS 430 : 1972	Specification for paint remover, solvent type, non-flammable (*second revision*)
IS 431 : 1972	Specification for Paint remover, solvent type, flammable (*second revision*)
IS 486 : 2023	Brushes, sash tool for paints and varnishes — Specification (*fifth revision*)
IS 487 : 2023	Brushes, paints and varnishes – Oval, ferrule bound; and round, ferrule bound (*sixth revision*)
IS 533:2007	Specification for gum spirit of turpentine (oil of turpentine) (*third revision*)
IS 644 : 2023	Dipentene for paints — Specification (*third revision*)
IS 5667 : 1970	Specification for thinner for cellulose nitrate based paints and lacquers
IS 14314 : 1995	Specification for thinner general purposes for synthetic paints and varnishes

d) Varnishes and Lacquers

IS 344 : 2023	Varnish stoving — Specification (*second revision*)
IS 347 : 2023	Varnish shellac for general purposes — Specification (*second revision*)
IS 348 : 1968	Specification for French polish (*first revision*)
IS 524 : 2024	Varnish for general purpose — Specification (*third revision*)
IS 642 : 2024	Varnish medium for aluminium paint — Specification *(second revision)*

IS 5691 : 2024	Lacquer, cellulose nitrate, pigmented, finishing, glossy — Specification (*first revision*)
IS 6127 : 2023	Varnish, spar and fungicidal — Specification (*first revision*)
IS 10018:1981	Specification for lacquer, cellulose, nitrate clear, finishing, glossy for wood

19 POLYMERS, PLASTICS AND GEOSYNTHETICS/GEOTEXTILES

IS No.	*Title*
IS 1998 : 1962	Methods of test for thermosetting synthetic resin bonded laminated sheets
IS 2036 : 1995	Specification for phenolic laminated sheets (*second revision*)
IS 2046 : 2025/ ISO 4586 : 2018	Decorative thermosetting synthetic resin bonded laminated sheets — Specification:
(Part 1) : 2025	Introduction and general information (*third revision*)
(Part 2) : 2025	Determination of properties (*third revision*)
(Part 3) : 2025	Classification and specifications for laminates less than 2 mm thick and intended for bonding to supporting substrates (*third revision*)
(Part 4) : 2025	Classification and specifications for compact laminates of thickness 2 mm and greater (*third revision*)
(Part 5) : 2025	Classification and specifications for flooring grade laminates less than 2 mm thick intended for bonding to supporting substrates (*third revision*)
(Part 6) : 2025	Classification and specifications for exterior-grade compact laminates of thickness 2 mm and greater (*third revision*)
(Part 7) : 2025	Classification and specifications for design laminates (*third revision*)
(Part 8) : 2025	Classification and specifications for alternative core laminates (*third revision*)
IS 2076 : 1981	Specification for unsupported polyvinyl chloride sheeting (*first revision*)
IS 2508 : 2024	Polyethylene films and sheets — Specification (*fourth revision*)
IS 6307 : 2023	Rigid PVC sheets — Specification (*second revision*)
IS 10889 : 2004	Specification for high density polyethylene films (*first revision*)
IS 12830:1989	Specification for rubber based adhesives for fixing PVC tiles to cement
IS 13162	Geotextiles — Methods of test:
(Part 2) : 2024	Determination of resistance to the exposure of ultraviolet light, moisture and heat (xenon-arc type apparatus) (*first revision*)
(Part 3) : 2021	Single layers (*first revision*)
(Part 4) : 2025	Dynamic perforation test (cone drop test) (*first revision*)
IS 13262 : 1992	Specification for pressure sensitive adhesive tapes with plastic base

IS No.	*Title*
IS 13325 : 1992	Method of test for the determination to tensile properties of extruded polymer geogrids using the wide strip
IS 13326 (Part 1) : 2025/ ISO 12957-1 : 2018	Geosynthetics — Determination of friction characteristics: Part 1 Direct shear test (*first revision*)
IS 14182 : 1994	Specification for solvent cement for use with unplasticized polyvinylchloride plastic pipe and fittings
IS 14293 : 2024	Geotextiles — Method for determination of trapezoid tearing strength (*first revision*)
IS 14294 : 2024	Geotextiles — Method for determination of apparent opening size by dry sieving technique (*first revision*)
IS 14324 : 2025/ ISO 11058 : 2019	Geotextiles and geotextile-related products — Determination of water permeability characteristics normal to the plane, without load (*first revision*)
IS 14443 : 1997	Specification for polycarbonate sheets
IS 14500 : 1998	Linear low-density polyethylene (LLDPE) films — Specification
IS 14643 : 1999	Specification for unsintered polytetrafluoroethylene (PTFE) Tape for thread sealing applications
IS 14706 : 2024/ ISO 9862 : 2023	Geosynthetics — Sampling and preparation of test specimens (*first revision*)
IS 14714 : 2024	Geotextiles — Determination of abrasion resistance (*first revision*)
IS 14715	Jute geotextiles:
(Part 1) : 2016	Strengthening of sub-grade in roads — Specification (*second revision*)
(Part 2) : 2016	Control of bank erosion in rivers and waterways — Specification (*second revision*)
IS 14716 : 2021	Geosynthetics — Test method for the determination of mass per unit area of geotextiles and geotextile-related products (*first revision*)
IS 14739 : 2026/ ISO 13431 : 1999	Geotextiles and geotextile-related products: Determination of tensile creep and creep rupture behaviour (*second revision*)
IS 14753 : 1999	Specification for poly(methyl) methacrylate (PMMA) (acrylic) sheets
IS 14986 : 2001	Guidelines for application of jute geotextile for rain water erosion control in road and railway embankments and hill slopes
IS 15060 : 2018/ ISO 10321 : 2008	Geosynthetics tensile test for joint seams by wide-width strip method (*first revision*)
IS 15351 : 2015	Agro textiles laminated high density polyethylene HDPE woven geomembrane for water proof lining — Specification (*second revision*)
IS 15869 : 2020	Textiles-Open weave coir Bhoovastra — Specification (*first revision*)
IS 15909 : 2020	PVC geomembranes for lining — Specification (*second revision*)

IS No.	*Title*
IS 16352 : 2020	Geosynthetics — High density polyethylene (HDPE) geomembranes for lining-specification (*first revision*)
IS 16362 : 2024	Geosynthetics — Geotextiles for subsurface drainage, subgrade separation, subgrade stabilization, filtration and erosion control (in hard armor systems) applications — Specification (*second revision*)
IS 16380 : 2020	Geosynthetics — Method of test for measuring pullout resistance of geosynthetics in soil (*first revision*)
IS 16483 : 2017	Geosynthetics — Method for microscopic evaluation of the dispersion of carbon black in polyolefin geosynthetics
IS 16493 : 2017	Geosynthetics — Method of test for determination of pyramid puncture resistance of unprotected and protected geomembranes
IS 16627 : 2017	Agro textiles — High density polyethylene (HDPE) laminated woven lay flat tube for use in mains and submains of drip irrigation system — Specification
IS 16635 : 2026	Geosynthetics — Wide-width tensile test (*first revision*)
IS 16653 : 2017	Geosynthetics — Needle punched nonwoven geobags for coastal and waterways protection — Specification
IS 16654 : 2017	Geosynthetics — Polypropylene multifilament woven geobags for coastal and waterways protection — Specification
IS 17179 : 2025/ ISO 12958 : 2020	Geotextiles and geotextile-related products — Determination of water flow capacity in their plane:
(Part 1)	Index text
(Part 2)	Performance test (*first revision*)
IS 17360 : 2020	Geosynthetics — Screening test method for determining the resistance of geotextiles and geotextile-related products to oxidation
IS 17363 : 2025	Geotextiles and geotextile-related products — Screening test method for determining the resistance to acid and alkaline liquids (*first revision*)
IS 17365 : 2025/ ISO/TS 20432 : 2022	Determination of the long-term strength of geosynthetics for soil reinforcement — Guidelines (*first revision*)
IS 17368 : 2020	Geosynthetics — Determination of damage to geosynthetic caused during installation
IS 17369	Geotextiles and geotextile-related products — Strength of internal structural junctions:
(Part 1) : 2020/ ISO 13426-1 : 2019	Geocells
(Part 2) : 2025/ ISO 13426-2 : 2005	Geocomposites (*first revision*)
IS 17371 : 2020	Geosynthetics — Geogrids for flexible pavements — Specification
IS 17372 : 2020	Geosynthetics — Polymeric strip/geostrip used as soil reinforcement in retaining structures — Specification

IS No.	*Title*
IS 17373 : 2020	Geosynthetics — Geogrids used in reinforced soil retaining structures — Specification
IS 17374 : 2020	Geosynthetics — Reinforced HDPE membrane for effluents and chemical resistance lining — Specification
IS 17420 : 2020	Geosynthetics — Index test procedure for the evaluation of mechanical damage under repeated loading-damage caused by granular material (laboratory test method)
IS 17483	Geosynthetics — Geocells — Specification:
(Part 1) : 2020	Load bearing application
(Part 2) : 2020	Slope erosion protection application
IS 17544 : 2022	Multilayer (PE-AL-PE) plastic piping system for indoor gas installations with a maximum operating pressure up to and including 500 KPA (5 Bar) — Specification
IS 17728 : 2021	Agro textiles — High density polyethylene (HDPE) laminated woven lay flat tube and fittings for use in rain irrigation system — Specification
IS 17880 : 2022	Geosynthetics — Synthetic polymer rope gabions for coastal and waterways protection — Specification
IS 18309 : 2023	Geosynthetics — Prefabricated vertical drains for quick consolidation of very soft plastic soil-Specification
IS 18998 : 2025/ ISO 24187 : 2023	Principles for the analysis of microplastics present in the environment
IS 19050 : 2025/ ISO 17541 : 2014	Plastics — Quantitative evaluation of scratch-induced damage and scratch visibility
IS 19169 : 2025/ ISO 21475 : 2019	Plastics — Methods of exposure to determine the wavelength dependent degradation using spectrally dispersed radiation
IS 19104 : 2025	Geosynthetics — Geotextile tubes for coastal and waterways protection — Specification
IS 19161 : 2025/ ISO 16869 : 2008	Plastics — Assessment of the effectiveness of fungistatic compounds in plastics formulations
IS 19162 : 2025/ ISO 15314 : 2018	Plastics — Methods for marine exposure
IS 19165 : 2025/ ISO 22196 : 2011	Measurement of antibacterial activity on plastics and other non-porous surfaces
IS 19166 : 2025/ ISO 10640 : 2011	Plastics — Methodology for assessing polymer photoageing by FTIR and UV/visible spectroscopy
IS 19167 : 2025/ ISO 21702 : 2019	Measurement of antiviral activity on plastics and other non-porous surfaces
IS 19168 : 2025/ ISO 29664 : 2010	Plastics — Artificial weathering including acidic deposition

IS No.	*Title*
IS 19218 : 2025	Textiles — Coir non-woven stitched composite geotextiles for erosion control applications — Specification

20 SANITARY APPLIANCES AND WATER FITTINGS

a) General

IS No.	*Title*
IS 804 : 1967	Specification for rectangular pressed steel tanks (*first revision*)
IS 906 : 2024	Portable and fixed type revolving branch for firefighting — Specification (*fourth revision*)
IS 1726 : 1991	Specification for cast iron manhole covers and frames (*third revision*)
IS 2963 : 2013	Copper alloy waste fittings and waste plug for wash-basins and sinks — Specification (*second revision*)
IS 5219 : 2013	Cast copper alloy traps — Specification (*first revision*)
IS 5455 : 1969	Specification for cast-iron steps for manholes
IS 5961 : 1970	Specification for cast iron gratings for drainage purposes
IS 9140 : 1996	Method of sampling of vitreous and fire clay sanitary appliances (*second revision*)
IS 9872 : 1981	Specification for precast concrete septic tanks
IS 12592 : 2002	Specification for precast concrete manhole covers and frames (*first revision*)
IS 12701 : 1996	Specification for rotational moulded polyethylene water storage tanks (*first revision*)
IS 13356 : 1992	Specification for precast ferrocement water tanks (250 to 10 000 litres capacity)
IS 14399	Hot press moulded thermosetting glass fibre reinforced (GRP) sectional water storage tanks:
(Part 1) : 1996	Specification for panels
(Part 2) : 1996	Guidelines for assembly, installation and testing
IS 17650	Water efficient plumbing products — Requirements:
(Part 1) : 2021	Sanitaryware
(Part 2) : 2021	Sanitary fittings
IS 18666 : 2024	Rotationally moulded polyethylene septic tanks — Specification
IS 18797 : 2024	Packaged sewage treatment plant — Specification
IS 19315 : 2025	Ball valves for water works purposes — Specification

b) Pipes and Fittings excluding valves

i) *Brass and Copper Pipes and Fittings*

IS No.	*Title*
IS 407 : 1981	Specification for brass tubes for general purposes (*third revision*)
IS 2501 : 1995	Specification for solid drawn copper tubes for general engineering purposes (*third revision*)

ii) *Cast Iron Pipes and Fittings*

IS No.	*Title*
IS 1536 : 2001	Specification for centrifugally cast (spun) iron pressure pipes for water, gas and sewage (*fourth revision*)
IS 1536 : 2023	Centrifugally cast spun iron pressure pipes for water gas and sewage specification (*fifth revision*)
IS 1537 : 1976	Specification for vertically cast iron pressure pipes for water, gas and sewage (*first revision*)
IS 1538 : 1993	Specification for cast iron fittings for pressure pipes for water, gas and sewage (*third revision*)
IS 1729 : 2023	Sand cast iron spigot and socket pipes, fittings and accessories — Specification (*third revision*)
IS 1729 : 2023	Sand cast iron spigot and socket pipes fittings and accessories — Specification (*third revision*)
IS 1879 : 2010	Malleable cast iron pipe fittings — Specification (*third revision*)
IS 3989 : 2024	Centrifugally cast (spun) iron spigot and socket pipes, fittings and accessories — Specification (*fourth revision*)
IS 5531 : 2014	Cast iron specials for asbestos cement pressure pipes for water and sewage — Specification (*third revision*)
IS 6418 : 1971	Specification for cast iron and malleable cast iron flanges for general engineering purposes
IS 7181 : 1986	Specification for horizontally cast iron double flanged pipes for water, gas and sewage (*first revision*)
IS 8329 : 2000	Specification for centrifugally cast (spun) ductile iron pressure pipes for water, gas and sewage (*third revision*)
IS 8794 : 1988	Specification for cast iron detachable joints for use with asbestos cement pressure pipes (*first revision*)
IS 9523 : 2000	Ductile iron fittings for pressure pipes for water gas and sewage — Specification (*first revision*)
IS 10292 : 1988	Dimensional requirements for rubber sealing rings for C.I.D. Joints in asbestos cement piping (*first revision*)

IS No.	*Title*
IS 10299 : 1982	Cast iron saddle pieces for service connection from asbestos cement pressure pipes
IS 11606 : 1986	Methods of sampling cast iron pipes & fittings
IS 12820 : 2004	Dimensional requirements of rubber gaskets for mechanical joints and push-on joints for use with cast iron pipes and fittings for carrying water gas and sewage (*first revision*)
IS 12987 : 1991	Cast iron detachable joints for use with asbestos cement pressure pipes (light duty) — Specification
IS 12988 : 1991	Rubber sealing rings for CID joints for light duty AC pipes — Dimensional requirements
IS 13382 : 2018	Cast iron specials for mechanical and push-on flexible joints for pressure pipes for water gas and sewage — Specification (*second revision*)
IS 15905 : 2024	Hubless centrifugally cast (spun) iron pipes, fittings and accessories — Spigot series — Specification (*first revision*)

iii) *Lead Pipes and Fittings*

IS No.	*Title*
IS 404 (Part 1) : 1993	Specification for lead pipes: Part 1 For other than chemical purpose (*third revision*)

iv) *Fibre Pipes and Fittings*

IS No.	*Title*
IS 11925 : 1986	Specification for pitch-impregnated fibre pipes and fittings for drainage purposes

v) *Plastic Pipes and Fittings*

IS No.	*Title*
IS 4984 : 2016	Polyethylene pipes for water supply — Specification (*fifth revision*)
IS 4985 : 2021	Unplasticized PVC pipes for potable water supplies — Specification (*fourth revision*)
IS 7834	Specification for injection moulded PVC socket fittings with solvent cement joints for water supplies:
(Part 1) : 1987	General requirements (*first revision*)
(Part 2) : 1987	Specific requirements for 45° elbows (*first revision*)
(Part 3) : 1987	Specific requirements for 90° elbows (*first revision*)
(Part 4) : 1987	Specific requirements for 90° tees (*first revision*)
(Part 5) : 1987	Specific requirements for 45° tees (*first revision*)

IS No.	*Title*
(Part 6) : 1987	Specific requirements for sockets (*first revision*)
(Part 7) : 1987	Specific requirements for unions (*first revision*)
(Part 8) : 1987	Specific requirements for caps (*first revision*)
IS 8008 : 2022	Injection moulded machined polyethylene fittings for water supply — Specification (*second revision*)
IS 8360 : 2022	Fabricated polyethylene fittings for water supply — Specification (*first revision*)
IS 10124	Specification for fabricated PVC fittings for potable water supplies:
(Part 1) : 2009	General requirements (*second revision*)
(Part 2) : 2009	Specific requirements for sockets (*second revision*)
(Part 3) : 2009	Specific requirements of straight reducers (*second revision*)
(Part 4) : 2009	Specific requirements for caps (*second revision*)
(Part 5) : 2009	Specific requirements for equal tees (*second revision*)
(Part 6) : 2009	Specific requirements for flanged tail piece with metallic flanges (*second revision*)
(Part 7) : 2009	Specific requirements for threaded adaptors (*second revision*)
(Part 8) : 2009	Specific requirements for 90° bends (*second revision*)
(Part 9) : 2009	Specific requirements for 60° bends (*second revision*)
(Part 10) : 2009	Specific requirements for 45° bends (*second revision*)
(Part 11) : 2009	Specific requirements for 30° bends (*second revision*)
(Part 12) : 2009	Specific requirements for 22½° bends (*second revision*)
(Part 13) : 2009	Specific requirements for 11¼° bends (*second revision*)
IS 12235	Methods of test for unplasticised PVC pipes for potable water supplies:
(Part 1) : 2004	Measurement of dimensions (*first revision*)
(Part 2) : 2004	Determination of Vicat softening temperature (*first revision*)
(Part 3) : 2004	Test for opacity (*first revision*)
(Part 4) : 2004	Determining the detrimental effect on the composition of water (*first revision*)
(Part 5)	Longitudinal reversion:
(Sec 1) : 2004	Determination methods (*first revision*)
(Sec 2) : 2004	Determination parameters (*first revision*)
(Part 6) : 2004	Stress relief test (*first revision*)
(Part 7) : 2004	Resistance to sulphuric acid (*first revision*)

IS No.	*Title*
(Part 8)	Resistance to internal hydrostatic pressure,
(Sec 1) : 2004	Resistance to internal hydrostatic pressure at constant internal water pressure (*first revision*)
(Sec 2) : 2004	Leak-tightness of elastomeric sealing ring type socket joints under positive internal pressure and with angular deflection (*first revision*)
(Sec 3) : 2004	Leak-tightness of elastomeric sealing ring type socket joints under negative internal pressure and with angular deflection (*first revision*)
(Sec 4) : 2004	Leak-tightness of elastomeric sealing ring type socket joints under positive internal pressure without angular deflection (*first revision*)
(Part 9) : 2004	Resistance to external blows (impact resistance) at 0 °C (Round-the-clock method)
(Part 10) : 2004	Determination of organotin as tin aqueous solution (*first revision*)
(Part 11) : 2004	Resistance to dichloromethane at specified temperature (*first revision*)
(Part 12) : 2004	Determination of titanium dioxide content
(Part 13) : 2004	Determination of tensile strength and elongation
(Part 14) : 2004	Determination of density/relative density (specific gravity)
(Part 15) : 2004	Determination of vinyl chloride monomer content
(Part 16) : 2004	High temperature test
(Part 17) : 2004	Determination of ash content and sulphated ash content
(Part 18) : 2004	Determination of ring stiffness
(Part 19) : 2004	Flattening test
IS 12709 : 1994	Specification for glass-fibre reinforced plastic (GRP) pipes joints and fittings for use for potable water supply (*first revision*)
IS 12818 : 2010	Specification for unplasticized PVC screen and casing pipes for bore/tubewell (*second revision*)
IS 13592:2013	Unplasticized polyvinyl chloride (PVC-U) pipes for soil and waste discharge systemfor inside and outside buildings including ventilation and rainwater system — Specification (*first revision*)
IS 14333 : 2022	Polyethylene pipes for sewerage and industrial chemicals and effluent — Specification (*first revision*)
IS 14402 : 1996	Specification for GRP pipes, joints and fittings for use for sewerage, industrial waste and water (other than potable)
IS14735 : 1999	Specification for unplasticized polyvinyl chloride (UPVC) injection moulded fittings for soil and waste discharge system for inside buildings including ventilation and rain water system

IS No.	*Title*
IS 14885 : 2022	Polyethylene pipes for the supply of gaseous fuels — Specification (*first revision*)
IS 15328:2003	Specification for unplasticized non-pressure polyvinyl chloride (PVC-U) pipes for use in underground drainage and sewerage system
IS 15450 : 2022	Polyethylene-aluminium-polyethylene composite pressure pipes for hot and cold water supplies — Specification (*first revision*)
IS 15778 : 2007	Chlorinated polyvinyl chloride (CPVC) pipes for potable hot and cold water distribution supplies — Specification
IS 15801 : 2008	Polypropylene-random copolymer pipes for hot and cold water supplies — Specification
IS 15927	Specification for polyethylene fittings for use with polyethylene pipes for the supply of gaseous fuels:
(Part 1) : 2012	Fittings for sockets using heated tools
(Part 2) : 2012	Spigot fittings for butt fusion jointing or socket fusion using heated tools, spigot fittings for use with electro-fusion fittings
(Part 3) : 2011	Electro-fusion fittings
IS 16098	Structured — wall plastics piping systems for non-pressure drainage and sewerage — Specification
(Part 1) : 2013	Pipes and fittings with smooth external surface, Type A
(Part 2) : 2013	Pipes and fittings with non-smooth external surface, Type B
IS 16534 : 2017	Chlorinated polyvinyl chloride (CPCV) Pipe fittings for automatic sprinkler fire extinguishing system — Specification
IS 16647 : 2017	Oriented unplasticized polyvinyl chloride (PVC-O) pipes for water supply — Specification
IS 17546 : 2021	Chlorinated polyvinyl chloride (CPVC) fittings for potable hot and cold water distribution supplies — Specification

vi) *Steel Tubes, Pipes and Fittings*

IS No.	*Title*
IS 1239	Steel tubes tubulars and other wrought steel fittings — Specification:
(Part 1) : 2004	Steel tubes (*sixth revision*)
(Part 2) : 2011	Steel pipe fittings (*fifth revision*)
IS 3589 : 2001	Steel pipes for water and sewage 1 683 mm to 2 540 mm outside diameter — Specification (*third revision*)
IS 4270 : 2001	Steel tubes used for water wells — Specification (*third revision*)
IS 5504 : 2025	Spiral welded pipes — Specification (*second revision*)

IS 6286 : 1971	Specification for seamless and welded steel pipe for sub-zero temperature service
IS 6392 : 2020	Steel pipes flanges — Specification (*first revision*)

vii) *Stoneware Pipes and Fittings*

IS No.	*Title*
IS 651 : 2007	Glazed stoneware pipes and fittings — Specification (*sixth revision*)
IS 3006 : 1979	Specification for chemically resistant glazed stoneware pipes and fittings (*first revision*)

viii) *Asbestos Cement Pipes*

[*See* 9 (a) (ii) under the category ‘Composite Matrix Products’]

ix) *Concrete Pipes and Pipes lined/coated with Concrete or Mortar*

[*See* 9 (a) (iv) under the category ‘Composite Matrix Products’]

c) Kitchen and Sanitary Appliances

IS No.	*Title*
IS 774 : 2021	Ceramic vitreous china flushing cisterns for water closets and urinals — Specification (*sixth revision*)
IS 2548	Specification for plastic seats and covers for water-closets:
(Part 1) : 1996	Thermoset seats and covers (*fifth revision*)
(Part 2) : 1996	Thermoplastic seats and covers (*fifth revision*)
IS 2556	Vitreous china sanitary appliances — Specification:
(Part 1) : 2021	General requirements (*fourth revision*)
(Part 2) : 2024	Specific requirements of washdown water closets (*sixth revision*)
(Part 3) : 2024	Specific requirements of squatting pans (*sixth revision*)
(Part 4) : 2004	Specific requirements of wash basins (*fourth revision*)
(Part 5) : 1994	Specific requirements of laboratory sinks (*third revision*)
(Part 6) : 2021	Specific requirements of urinal and partition plates (*fifth revision*)
(Part 7) : 1995	Specific requirements of accessories for sanitary appliances (*third revision*)
(Part 8) : 2021	Specific requirements of close coupled and one-piece pedestal washdown and syphonic water closets (*sixth revision*)
(Part 9) : 2004	Specific requirements of pedestal type bidets (*fifth revision*)
(Part 14) : 2024	Specific requirements of integrated squatting pans (*second revision*)
(Part 15) : 2024	Specific requirements of universal water closets (*third revision*)

IS No.	*Title*
(Part 16) : 2024	Specific requirements of washdown wall mounted water closets (*first revision*)
(Part 17) : 2001	Specific requirements of wall mounted bidets
IS 6411 : 1985	Specification for gel-coated glass fibre reinforced polyester resin bath tubs (*first revision*)
IS 7231 : 2021	Plastic flushing cisterns for water closets and urinals — Specification (*third revision*)
IS 11246 : 1992	Specification for glass fibre reinforced polyester resins (GRP) squatting pans (*first revision*)
IS 13983 : 1994	Specification for stainless steel sinks for domestic purposes

d) Valves and Water Fittings (Including Ferrules)

IS No.	*Title*
IS 778 : 1984	Specification for copper alloy gate, globe, and check valves for water works purposes (*fourth revision*)
IS 781 : 1984	Specification for cast copper alloy screw-down bib taps and stop valves for water services (*third revision*)
IS 1701 : 1960	Specification for mixing valves for ablutionary and domestic purposes
IS 1703 : 2000	Water fittings — Copper alloy float valves (horizontal plunger type) — Specification (*fourth revision*)
IS 1711 : 1984	Specification for self-closing taps for water supply purposes (*second revision*)
IS 1795 : 1982	Specification for pillar taps for water supply purposes (*second revision*)
IS 2692 : 1989	Specification for ferrules for water services (*second revision*)
IS 3004 : 1979	Specification for plug cocks for water supply purposes (*first revision*)
IS 3042 : 1965	Specification for single faced sluice gates (200 mm to1 200 mm size)
IS 3950 : 1979	Specification for surface boxes for sluice valves (*first revision*)
IS 4038 : 1986	Specification for foot valves for water works purposes (*second revision*)
IS 4346 : 1982	Specification for washers for use with fittings for water services (*first revision*)
IS 5312	Specification for swing check type reflux (non-return) valves:
(Part 1) : 2004	Single door pattern (*second revision*)
(Part 2) : 2013	Multi-door pattern (*first revision*)
IS 8931 : 2021	Copper alloy single taps combination tap assemblies stop valves and single lever mixers for water services — Specification (*second revision*)
IS 9338 : 2013	Cast iron/S.G. iron, cast steel screw-down stop valves for water works purposes — Specification (*second revision*)

IS No.	*Title*
IS 9739 : 1981	Specification for pressure reducing valves for domestic water supply systems
IS 9758 : 1981	Specification for flush valves and fittings for water-closets and urinals
IS 9762 : 1994	Specification for polyethylene floats (spherical) for float valves (*first revision*)
IS 9763 : 2000	Plastic bib taps, pillar taps, angle valves, hot and cold water services — Specification (*second revision*)
IS 12234 : 2021	Plastic equilibrium float valves for cold water services — Specification *(first revision*)
IS 13049 : 1991	Specification for diaphragm type (plastic body) float operated valves for cold water services
IS 13114 : 1991	Specification for forged brass gate, globe and check valves for water works purposes
IS 13349 : 1992	Specification for single faced cast iron thimble mounted sluice gates
IS 14845 : 2000	Resilient seated cast iron air relief valves for water works purposes — Specification
IS 14846 : 2000	Sluice valves for water works purposes (50 mm to 1 200 mm) — Specification
IS 17585 : 2021	Beta (Outflow) valves for gravity type flushing cisterns — Specification

e) Water Meters

IS No.	*Title*
IS 779 : 1994	Specification for water meters (domestic type) (*sixth revision*)
IS 2373 : 1981	Specification for water meters (bulk type) (*third revision*)
IS 6784 : 1996	Method for performance testing of water meters (domestic type) (*second revision*)

21 STEEL AND ITS ALLOYS (*See* 23 FOR STRUCTURAL SECTIONS)

a) General

IS No.	*Title*
IS 1030 : 1998	Carbon steel castings for general engineering purposes (*fifth revision*)
IS 1136 : 2008	Preferred sizes for wrought metal products (*third revision*)
IS 1762 (Part 1) : 1974	Code for designation of steels: Part 1 Based on letter symbols (*first revision*)
IS 2049 : 1978	Colour code for the identification of wrought steel for general engineering purposes (*first revision*)
IS 2644 : 1994	High strength steel castings for general engineering and structural purposes — Specification (*fourth revision*)
IS 2708 : 1993	1.5 percent manganese steel castings for general engineering purposes — Specification (*third revision*)

IS No.	*Title*
IS 7598 : 1990	Classification of steels (*first revision*)
IS 10461	Resistance to inter-granular corrosion of austenitic stainless steels — Method for determination:
(Part 1) : 2025	Corrosion test in nitric acid medium by measurement of loss in mass (Huey Test) (*second revision*)
(Part 2) : 1994	Corrosion test in a sulphuric acid/copper sulphate medium in the presence of copper turnings (Monypenny strauss test) (*first revision*)
IS/ISO 11951 : 2016	Cold-reduced tinmill products — Blackplate *(first revision)*
IS 12591 : 2018	Cold-reduced tinmill products — Electrolytic chromium/chromium oxide — Coated steel (*second revision*)
IS 14126 : 2019	Metallic coatings — Measurement of coating thickness — Coulometric method by anodic dissolution (*first revision*)
IS 16733 : 2018	Ferritic-pearlitic engineering steels for precipitation hardening from hot-working temperatures
IS 16854 : 2018	Single pack zinc rich coating for cold application — Specification
IS 17111 : 2025/ ISO 683-17 : 2023	Heat-Treatable steels, alloy steels and free-cutting steels — Ball and roller bearing steels (*first revision*)
IS 18435 (Part 11) : 2023	Corrosion of metals and alloys — Stress corrosion testing: Part 11 Testing the resistance of metals and alloys to hydrogen embrittlement and hydrogen-assisted cracking — Guidelines
IS 18436 : 2023	Metallic and other inorganic coatings — Post-coating treatments of iron or steel to reduce the risk of hydrogen embrittlement
IS 18437 : 2023/ ISO 15324 : 2000	Corrosion of metals and alloys — Evaluation of stress cracking by the drop evaporation test
IS 18438 : 2023/ ISO 18069 : 2015	Corrosion of metals and alloys — Method for determination of the uniform corrosion rate of stainless steels and nickel based alloys in liquids
IS 18463 : 2023/ ISO 9587 : 2007	Metallic and other inorganic coatings — Pretreatment of iron or steel to reduce the risk of hydrogen embrittlement

b) Structural Steel

IS No.	*Title*
IS 1161 : 2014	Steel tubes for structural purposes — Specification (*fifth revision*)
IS 2062	Structural steel
(Part 1) : 2025	Hot rolled medium and high tensile steel (*eight revision*)
(Part 2) : 2025	Hot rolled quenched and tempered steel plates, sheets, strips and wide flats
IS 2830 : 2012	Specification for carbon steel cast billet ingots, billets, blooms and slabs for re-rolling into steel for general structural purposes (*third revision*)

IS No.	*Title*
IS 2831 : 2012	Specification for carbon steel billets ingots, blooms and slabs for re-rolling into structural steel (ordinary quality) (*fourth revision*)
IS 4923 : 2017	Hollow steel sections for structural use — Specification (*third revision*)
IS 8052 : 2006	Specification for steel ingots, billets and blooms for the production of springs, rivets and screws for general engineering applications (*second revision*)
IS 8952 : 1995	Steel ingots, blooms and billets for production of mild steel wire rods for general engineering purposes (*first revision*)
IS 11587 : 1986	Specification for structural weather resistant steels
IS 15103 : 2002	Fire resistant steel — Specification
IS 15911 : 2010	Structural steel (Ordinary quality) — Specification
IS 15962 : 2012	Structural steels for buildings and structures with improved seismic resistance
IS 16732 : 2019	Galvanized structural steel — Specification

c) Sheet and Strip

IS No.	*Title*
IS 277 : 2018	Galvanized steel strips and sheets plain and corrugated — Specification (*seventh revision*)
IS 412 : 1975	Specification for expanded metal steel sheets for general purposes (*second revision*)
IS 513	Cold reduced carbon steel sheet and strip:
(Part 1) : 2016	Cold forming and drawing purpose (*sixth revision*)
(Part 2) : 2016	High tensile and multi-phase steel (*sixth revision*)
IS 1079 : 2017	Hot rolled carbon steel sheet plate and strip — Specification (*seventh revision*)
IS 6911 : 2026	Stainless steel plate sheet and strip — Specification (*third revision*)
IS 7226 : 1974	Specification for cold rolled medium, high carbon and low alloy steel strip for general engineering purposes
IS 14246 : 2024	Continuously pre-painted galvanized steel sheets and strips — Specification (*second revision*)
IS 15961 : 2025	Hot-dip alumnium zinc alloy metallic coated steel strip and sheet — Specification (*first revision*)
IS 15965 : 2012	Pre-painted aluminium zinc alloy metallic coated steel strip & sheet (plain)
IS 18513 : 2023	Hot-dip zinc-aluminium-magnesium alloy coated steel sheets plates and strips — Specification
IS 18733 : 2024/ ISO 11531 : 2022	Metallic materials — Sheet and strip — Earing test

IS No.	*Title*
IS 19210 : 2025	Pre-Painted Zinc-aluminium-magnesium alloy coated steel strip and sheet
IS 19474 : 2026	Hot-dip aluminium and aluminium-silicon coated steel sheet and strip — Specification
IS 19608 : 2026	Hot-rolled carbon and alloy steel plates, sheets and strips — Specification
IS 19626 : 2026	Electrolytic Zinc-nickel alloy coated steel sheet and strip — Specification

d) Bars, Rods, Wire and Wire Rods

IS No.	*Title*
IS 280 : 2006	Mild steel wire for general engineering purposes — Specification (*fourth revision*)
IS 1148 : 2009	Steel rivet bars medium and high tensile — For structural purposes — For structural purposes (*fourth revision*)
IS 1673 : 1984	Specification for mild steel wire cold heading quality (*second revision*)
IS 1812 : 1982	Specification for carbon steel wire for the manufacture of wood screw (*second revision*)
IS 1835 : 1976	Specification for round steel wire for ropes (*third revision*)
IS 1875 : 2025	Steel ingots, billets, blooms, slabs, and bars for forging — Specification (*sixth revision*)
IS 1921 : 2025	Solder wire — Solid and flux cored — Specification (*third revision*)
IS 2591 : 1982	Dimensions for hot rolled bars for threaded components (*second revision*)
IS 3150 : 1982	Specification for hexagonal wire netting for general purposes
IS 4826 : 2023	Hot-dip galvanized coatings on round steel wires requirements (*second revision*)
IS 6528 : 2024	Stainless steel wire — Specification (*second revision*)
IS 6603 : 2024	Stainless steel semi-finished products, bars, wire rods and bright bars — Specification (*second revision*)
IS 7887:1992	Specification for mild steel wire rods for general engineering purposes (*first revision*)
IS 7904 : 2018	High carbon steel wire rods — Specification (*second revision*)
IS 10631 : 1983	Stainless steel for welding electrode core wire
IS/ISO 16124 : 2015/ ISO 16124 : 2015	Steel wire rod — Dimensions and tolerances (*first revision*)

e) Plates and Studs

IS No.	*Title*
IS 1862 : 1975	Specification for studs (*second revision*)
IS 3502 : 2009	Specification for steel chequered plates (*third revision*)

f) Tubes and Tubulars

IS No.	*Title*
IS 1161 : 2014	Specification for steel tubes for structural purposes (*fifth revision*)
IS 4923 : 2017	Hollow steel sections for structural use — Specification (*third revision*)
IS 17875 : 2022	Stainless steel seamless pipes and tubes for general services — Specification
IS 17876 : 2022	Stainless steel welded pipes and tubes for general services — Specification

g) Slotted Sections

IS No.	*Title*
IS 8081 : 1976	Specification for slotted sections

22 STONES

IS No.	*Title*
IS 1121	Methods of test for determination of strength properties of natural building stones:
(Part 1) : 2023	Compressive strength (*third revision*)
(Part 2) : 2023	Transverse strength (*third revision*)
(Part 3) : 2023	Indirect tensile strength (*third revision*)
(Part 4) : 2013	Shear strength (*second revision*)
(Part 5) : 2023	Flexural modulus of elasticity
IS 1122 : 2023	Determination of true specific gravity of natural building stones — Method of test (*second revision*)
IS 1123 : 1975	Method of identification of natural building stones (*first revision*)
IS 1124 : 1974	Method of test for determination of water absorption, apparent specific gravity and porosity of natural building stones (*first revision*)
IS 1125 : 2013	Method of test for determination of weathering of natural building stones (*second revision*)
IS 1126 : 2013	Method of test for determination of durability of natural building stones (*second revision*)
IS 1127 : 1970	Recommendations for dimensions and workmanship of natural building stones for masonry work (*first revision*)
IS 1128 : 1974	Specification for limestone (slab and tiles) (*first revision*)
IS 1129 : 1972	Recommendation for dressing of natural building stones (*first revision*)
IS 1130 : 1969	Specification for marble (blocks, slabs and tiles)

IS No.	*Title*
IS 1706 : 2024	Determination of resistance to wear by abrasion of natural building stones — Method of test (*second revision*)
IS 3316 : 1974	Specification for structural granite (*first revision*)
IS 3620 : 1979	Specification for laterite stone block for masonry (*first revision*)
IS 3622 : 1977	Specification for sand stone (slabs and tiles) (*first revision*)
IS 4121 : 1967	Method of test for determination of water transmission rate by capillary action through natural building stones
IS 4122 : 1967	Method of test for surface softening of natural building stones by exposure to acidic atmospheres
IS 4348 : 2024	Determination of permeability of natural building stones — Methods of test (*second revision*)
IS 5218 : 1969	Method of test for toughness of natural building stones
IS 5640 : 1970	Method of test for determining the aggregate impact value of soft coarse aggregates
IS 6241 : 2024	Determination of stripping value of road aggregates — Method of test (*first revision*)
IS 6250 : 1981	Specification for roofing slate tiles (*first revision*)
IS 6579 : 1981	Specification for coarse aggregate for water bound macadam (*first revision*)
IS 7779	Schedule for properties and availability of stones for construction purposes:
(Part 1)	Gujarat State,
(Sec 1) : 1975	Availability of stones
(Sec 2) : 1975	Engineering properties of building stones
(Sec 3) : 1975	Engineering properties of stone aggregates
(Part 2)	Maharashtra state,
(Sec 1) : 1979	Availability of stones
(Sec 2) : 1979	Engineering properties of building stones
(Sec 3) : 1979	Engineering properties of stone aggregates
(Part 3)	Tamil Nadu state,
(Sec 2) : 1980	Engineering properties of building stones
(Sec 3) : 1980	Engineering properties of stone aggregates
(Part 4/Sec 1 to 3) : 1996	Karnataka state, Sections (1 to 3)
(Part 5)	Andhra Pradesh,
(Sec 1) : 1997	Availability of stones

IS No.	*Title*
(Sec 2) : 1997	Engineering properties of building stones
(Sec 3):1997	Engineering properties of stone aggregates
IS 8759 : 2024	Maintenance and preservation of stone in buildings — Code of practice (*first revision*)
IS 9394 : 2024	Stone lintels — Specification (*first revision*)
IS 14223	Polished building stones specification:
(Part 1) : 2023	Granite and similar stones (*first revision*)
(Part 2) : 2025	Marble and similar stones

23 STRUCTURAL SECTIONS

a) Structural Shapes

IS No.	*Title*
IS 811 : 1987	Specification for cold formed light gauge structural steel sections (*second revision*)
IS 1173 : 2025	Hot rolled and slit steel tee bars — Dimensions and properties (*third revision*)
IS 1863 : 1979/ ISO 657-19	Rolled steel bulb flats (*first revision*)
IS 2314	Steel sheet piling section specification:
(Part 1) : 2023	Hot rolled sheet pile (*second revision*)
(Part 2) : 2023	Cold formed sheet pile (*second revision*)
IS 3443 : 1980	Specification for crane rail sections (*first revision*)
IS 3908 : 2025	Aluminium beam, channel and angle sections — Dimensions and properties (*second revision*)
IS 3964 : 1980	Specification for light rails (*first revision*)
IS 6445 : 1985	Specification for aluminium tee sections (*first revision*)

b) Dimensional Standards

IS No.	*Title*
IS 808 : 2021	Hot rolled steel beam column channel and angle sections — Dimensions and properties (*fourth revision*)
IS 1730 : 1989	Dimensions for steel plates, sheets strips and flats for general engineering purposes (*second revision*)
IS 1732 : 1989	Dimensions for round and square steel bars for structural and general engineering purposes (*second revision*)
IS 1852 : 1985	Rolling and cutting tolerances for hot rolled steel products (*fourth revision*)

IS No.	*Title*
IS 2525 : 1982	Dimensions for wrought aluminium and aluminium alloy wire (*first revision*)
IS 2591 : 1982	Dimensions for hot rolled steel bars for threaded components (*second revision*)
IS 2673 : 2002	Dimensions for wrought aluminium and aluminium alloys, extruded round tube (*second revision*)
IS 2676 : 1981	Dimensions for wrought aluminium and aluminium alloys, sheet and strip (*first revision*)
IS 2677 : 1979	Dimensions for wrought aluminium and aluminium alloys, plates and hot rolled sheets (*first revision*)
IS 2678 : 1987	Dimensions and tolerances for wrought aluminium and aluminium alloys, drawn round tubes (*second revision*)
IS 3577 : 1992	Dimensions and tolerances for wrought aluminium and aluminium alloys rivet, bolt and screw stock (*first revision*)
IS 3954 : 1991	Hot rolled steel channel sections for general engineering purposes — Dimensions (*first revision*)
IS 3965 : 1981	Dimensions for wrought aluminium and aluminium alloys, bar, rod and section (*first revision*)
IS 6477 : 1983	Dimensions for wrought aluminium and aluminium alloys, extruded hollow sections (*first revision*)
IS 12779 : 1989	Rolling and cutting tolerances for hot rolled parallel flange beam and column sections
IS/ISO 16124 : 2015	Steel wire rod — Dimensions and tolerances (*first revision*)
IS/ISO 16160 : 2012	Hot-rolled steel sheet products dimensional and shape tolerances (*first revision*)
IS/ISO 16162 : 2012	Cold-rolled steel sheet products — Dimensional and shape tolerances (*first revision*)
IS/ISO 16163 : 2012	Continuously hot-dipped coated steel sheet products — Dimensional and shape tolerances (*first revision*)
IS 16998 : 2018	Hot-rolled steel plates — Tolerances on dimensions and shape

24 THERMAL INSULATION MATERIALS

IS No.	*Title*
IS 3144 : 2024	Mineral wool thermal insulation materials — Methods of test (*third revision*)
IS 3346 : 1980	Methods for the determination of thermal conductivity of thermal insulation materials (two slab, guarded hot-plate method (*first revision*)

IS No.	*Title*
IS 3677 : 2026	Unbonded rock and slag wool for thermal insulation — Specification (*third revision*)
IS 4671 : 2018	Expanded polystyrene for thermal insulation purposes (*second revision*)
IS 5688 : 2018	Methods of test for preformed block-type and pipe-covering type thermal insulation (*second revision*)
IS 5724 : 2018	Thermal insulating cements — Methods of test (*first revision*)
IS 6598 : 2018	Cellular concrete for thermal insulation — Specification (*first revision*)
IS 7509 : 2024	Thermal insulating cements — Specification (*second revision*)
IS 8154 : 2024	Preformed calcium silicate insulation for temperatures up to 650 °C — Specification (*second revision*)
IS 8183 : 2024	Bonded mineral wool — Specification (*second revision*)
IS 9403 : 2018	Method of test for thermal conductance and transmittance of built-up Section by means of guarded hot box (*first revision*)
IS 9489 : 2018	Method of test for thermal conductivity of thermal insulation materials by means of heat flow meter (*first revision*)
IS 9490 : 2018	Method for determination of thermal conductivity of thermal insulation materials water calorimeter method (*first revision*)
IS 9742 : 2024	Sprayed mineral wool thermal insulation — Specification (*second revision*)
IS 9743 : 2020	Thermal insulation finishing cement — Specification (*second revision*)
IS 9842 : 2024	Preformed fibrous pipe insulation – Specification (*second revision*)
IS 11128 : 2018	Spray applied hydrated calcium silicate thermal insulation (*first revision*)
IS 11129 : 2018	Method of test for tumbling friability of preformed block-type thermal insulation (*first revision*)
IS 11239	Methods of test for rigid cellular thermal insulation materials:
(Part 1) : 2009/ ISO 1923 : 1981	Dimensions (*first revision*)
(Part 2) : 2019/ ISO 845 : 2006	Apparent density (*second revision*)
(Part 3) : 2009/ ISO 2796 : 1986	Dimensional stability (*first revision*)
(Part 4) : 2025/ ISO 1663 : 2023	Water vapour transmission rate (*second revision*)
(Part 5) : 2019/ ISO 4590 : 2016	Volume percent of open and closed cells (*second revision*)
(Part 6) : 1985	Heat distortion temperature
(Part 7) : 1985	Coefficient of linear thermal expansion at low temperatures

IS No.	*Title*
(Part 8) : 2024	Flame height, time of burning and loss of mass (*first revision*)
(Part 9) : 1988	Water absorption
(Part 10) : 1985	Flexural strength
(Part 11) : 2024	Compressive strength (*first revision*)
(Part 12) : 1988	Horizontal burning characteristics
(Part 14) : 1992	Determination of flammability by oxygen index
IS 11307 : 2025	Specification for cellular glass block and pipe thermal insulating (*first revision*)
IS 11308 :2024	Hydraulic setting thermal insulating castables for temperatures up to 1 250 °C — Specification (*first revision*)
IS 12436 : 1988	Specification for preformed rigid polyurethane (PUR) and polyisocyanurate (PIR) foams for thermal insulation
IS 13204 : 2024	Specification for rigid phenolic foams for thermal insulation (*first revision*)
IS 13286 : 2025	Methods of test for surface spread of flame for thermal insulation materials (*first revision*)
IS 14656 : 2026	Ceramic fibre products — Methods of test (*first revision*)

25 THREADED FASTENERS, RIVETS AND NAILS

IS No.	*Title*
IS 207 : 1964	Specification for gate and shutter hooks and eyes (*revised*)
IS 451 : 1999	Specification for technical supply conditions for wood screws (*third revision*)
IS 554 : 1999	Specification for pipe threads where pressure-tide joints are made on the threads — Dimensions, tolerances and designation (*fourth revision*)
IS 723 : 2023	Steel countersunk head wire nails — Specification (*second revision*)
IS 724 : 2023	Mild steel and brass cup, ruler and square hooks and screw eyes — Specification (*second revision*)
IS 725 : 1961	Specification for copper wire nails (*revised*)
IS 730 : 2021	Specification for hook bolts for corrugated sheet roofing (*third revision*)
IS 1120 : 1975	Specification for coach screws (*first revision*)
IS 1363	Hexagon head bolts, screws and nuts of product grade C:
(Part 1) : 2023/ ISO 4016 : 2022	Hexagon head bolts (size range M5 to M64) (*sixth revision*)
(Part 2) : 2023/ ISO 4018 : 2022	Hexagon head screws (size range M5 to M64) (*sixth revision*)

IS No.	*Title*
(Part 3) : 2018/ ISO 4034 : 2012	Style 1 Hexagon nuts (size range M5 to M64) (*fifth revision*)
IS 1364	Hexagon head bolts, screws and nuts of property grades A and B:
(Part 1) : 2023/ ISO 4014 : 2022	Hexagon head bolts (size range M1.6 to M64) (*sixth revision*)
(Part 2) : 2023/ ISO 4017 : 2022	Hexagon head screws (size range M1.6 to M64) (*sixth revision*)
(Part 3) : 2026/ ISO 4032 : 2023	Hexagon nuts, style 1 (size range M5 to M39) (*sixth revision*)
(Part 4) : 2025/ ISO 4035 : 2023	Hexagon nuts, style 0 (size range M1.6 to M64) (*fifth revision*)
(Part 5) : 2002/ ISO 4036 : 1999	Hexagon thin nuts — Product grade B (unchamfered) (size range M 1.6 to M10) (*fourth revision*)
(Part 6) : 2025/ ISO 4033 : 2023	Hexagon nuts, style 2 (Size Range M5 to M39) (*second revision*)
IS 1365 : 2022/ ISO 2009 : 2011	Slotted countersunk flat head screws — Product grade A (*fifth revision*)
IS 1366 : 2022/ ISO 1207 : 2011	Slotted cheese head screws — Product grade A (*fourth revision*)
IS 1367	Technical supply conditions for threaded steel fasteners:
(Part 1) : 2014/ ISO 8992 : 2005	General requirements for bolts, screws, studs and nuts (*fourth revision*)
(Part 2) : 2002/ ISO 4759-1 : 2000	Tolerances for fasteners — Bolts, screws, studs and nuts — Product grades a b and c (*third revision*)
(Part 3) : 2017/ ISO 898-1 : 2013	Mechanical properties of fasteners made of carbon steel and bolts, screws and studs (*fifth revision*)
(Part 5) : 2018 ISO 898-5 : 2012	Mechanical properties of fasteners made of carbon steel and alloy steel — Set screws and similar threaded fasteners with specified hardness classes-Coarse thread and fine pitch thread (*fourth revision*)
(Part 6) : 2025/ ISO 898-2:2022	Mechanical properties of fasteners made of carbon steel and alloy steel — Nuts with specified property classes (*fifth revision*)
(Part 7) : 1980	Mechanical properties and test methods for nuts without specified proof loads (*second revision*)
(Part 8) : 2020/ ISO 2320 : 2015	Prevailing torque type steel nuts functional properties (*fifth revision*)
(Part 9)	Surface discontinuities,
(Sec 1) : 1993/ ISO 6157-1 : 1988	Bolts screws and studs for general applications (*third revision*)

IS No.	*Title*
(Sec 2) : 1993/ ISO 6167-3 : 1988	Bolts screws and studs for special applications (*third revision*)
(Part 10) : 2002/ ISO 6157-2 : 1995	Surface discontinuities — Nuts (*third revision*)
(Part 11) : 2024/ ISO 4042 : 2022	Electroplated coating systems (*fifth revision*)
(Part 12) : 1981	Phosphate coatings on threaded fasteners (*second Revision*)
(Part 13) : 2020/ ISO 10684 : 2004	Hot dip galvanized coatings on threaded fasteners (*third Revision*)
(Part 14)	Mechanical properties of corrosion-resistant stainless steel fasteners,
(Sec 1) : 2023/ ISO 3506-1 : 2020	Bolts screws and studs with specified grades and property classes (*fifth revision*)
(Sec 2) : 2023/ ISO 3506-2 : 2020	Nuts with specified grades and property classes (*fifth revision*)
(Sec 3) : 2018/ ISO 3506-3 : 2009	Set screws and similar fasteners not under tensile stress (*fourth revision*)
(Sec 4) : 2023/ ISO 3506-4 : 2009	Tapping screws
(Part 16) : 2002/ ISO 8991 : 1986	Designation system for fasteners (*third revision*)
(Part 17) : 2023/ ISO 3269 : 2019	Inspections, sampling and acceptance procedure (*fifth revision*)
IS 1367	Industrial fasteners — Threaded steel fasteners — Technical supply conditions:
(Part 18) : 1996	Packaging (*third revision*)
(Part 19) : 1997/ ISO 3800 : 1993	Axial load fatigue testing of bolts screws and studs
(Part 20) : 1996/ ISO 896-7 : 1992	Torsional test and minimum torques for bolts and screws with nominal diameters 1 mm to 10 mm
IS 1929 : 1982	Specification for hot forged steel rivets for hot closing (12 mm to 36 mm diameter) (*first revision*)
IS 2016 : 1967	Specification for plain washers (*first revision*)
IS 2155 : 1982	Specification for cold forged solid steel rivets for hot closing (6 mm to 16 mm diameter) (*first revision*)
IS 2269 : 2006	Hexagon socket head cap screws (*fifth revision*)
IS 2585 : 2006	Square head bolts, screws and square nuts of product Grade C — Specification (*second revision*)

IS No.	*Title*
IS 2609 : 1972	Specification for coach bolts (*first revision*)
IS 2643 : 2005	Pipe threads where pressure-tight joints are not made on the threads — Dimensions, tolerances and designation (*third revision*)
IS 2687 : 1991	Specification for cap nuts (*second revision*)
IS 2769 : 1969	Sizes for squares and square holes for general engineering purposes (*first revision*)
IS 2907 : 1998	Specification for non-ferrous rivets (*first revision*)
IS 2998 : 1982	Specification for cold forged steel rivets for cold closing (1 mm to 16 mm diameter) (*first revision*)
IS 3063 : 1994	Specification for fasteners single coil rectangular section spring lock washers (*second revision*)
IS 3121 : 2023	Rigging screws and stretching screws — Specification (*second revision*)
IS 3468:1991	Specification for pipe nuts (*second revision*)
IS 3640 : 1982	Specification for hexagon fit bolts (*first revision*)
IS 3757 : 1985	Specification for high strength structural bolts (*second revision*)
IS 4206 : 2018/ ISO 888 : 2012	Dimensions for nominal lengths and thread lengths for bolts screws and studs *(second revision)*
IS 4762 : 2002	Fasteners — Worm drive hose clamps for general purposes — Specification (*second revision*)
IS 5370 : 1969	Specification for plain washers with outside diameter ≈ 3 × inside diameter
IS 5372 : 1975	Specification for taper washer for channels (ISMC) (*first revision*)
IS 5373 : 1969	Specification for square washers for wood fastenings
IS 5374 : 1975	Specification for taper washers for l-beam (ISMB) (*first revision*)
IS 5624 : 2021	Foundation bolts – Specification (*second revision*)
IS 6101 : 2018	Slotted pan head screws — Product Grade A (*third revision)*
IS 6113 : 1970	Specification for aluminium fasteners for building purposes
IS 6610 : 1972	Specification for heavy washers for steel structures
IS 6623 : 2004	High strength structural nuts — Specification (*second revision*)
IS 6639 : 1972	Specification for hexagon bolts for steel structures
IS 6649 : 1985	Specification for hardened and tempered washers for high strength structural bolts and nuts (*first revision*)
IS 6733 : 1972	Specification for wall and roofing nails
IS 6736 : 1972	Specification for slotted raised countersunk head wood screws

IS No.	*Title*
IS 6739 : 1972	Specification for slotted round head wood screws
IS 6760 : 1972	Specification for slotted countersunk head wood screws
IS 6761 : 2023	Fasteners — Hexagon socket countersunk head screws with reduced loadability (*third revision*)
IS 7002 : 2018	Prevailing torque type hexagon regular nuts (with non-metallic insert) — Property classes 5,8 and 10 (*third revision*)
IS 7178 : 2018	Heat-Treated steel tapping screws — Mechanical properties (*fourth revision*)
IS 7483 : 2018/ ISO 7045 : 2011	Pan head screws with type H or type Z cross recess — Product grade A (*third revision*)
IS 7485	Countersunk flat head screws (common head style) with Type H or Type Z cross recess — Product grade A:
(Part 1) : 2018/ ISO 7046-1 : 2011	Steel screws of property class 4.8 (*third revision*)
(Part 2) : 2018/ ISO 7046-2 : 2011	Steel screws of property class 8.8, stainless steel screws and non- ferrous metal screws (*third revision*)
IS 7486 : 2018/ ISO 7047 : 2011	Raised countersunk head screws (common head style) with type H or type Z cross recess — Product grade A (*third revision*)
IS 8033 : 1976	Specification for washers with square hole for wood fastenings
IS 8412 : 1977	Specification for slotted countersunk head bolts for steel structures
IS 8536 : 2021/ ISO 225 : 2010	Fasteners — Bolts, screws, studs and nuts — Symbols and descriptions of dimensions (*second revision*)
IS 8822 : 1978	Specification for slotted mushroom head roofing bolts
IS 8869 : 1978	Specification for washers for corrugated sheet roofing
IS 8911 : 2018/ ISO 2010 : 2011	Slotted raised countersunk head screws — Product grade A (*second revision*)
IS 10102 : 1982	Specification for technical supply conditions for rivets
IS 10238 : 2001	Fasteners — Threaded steel fasteners — Step bolts for steel structures — Specification (*first revision*)
IS/ISO 10683 : 2018	Fasteners — Non electrolytically applied zinc flake coating systems
IS 12427 : 2001	Threaded steel fasteners — hexagon head transmission tower bolts — Specification (*first revision*)
IS 13722 : 2025/ ISO 8673 : 2023	Hexagon regular nuts (Style 1) with metric fine pitch thread — Product grades A and B — Specification (*third revision*)
IS 13723 : 2025/ ISO 8674 : 2023	Hexagon high nuts (Style 2) with metric fine pitch thread — Product grades A and B — Specification (*third revision*)
IS 13724 : 2025/ ISO 8675 : 2023	Hexagon thin nuts (Style 0) with metric fine pitch thread — Product grades A and B — Specification (*third revision*)

IS No.	*Title*
IS 13725 : 2023/ ISO 8676 : 2022	Hexagon head screws with metric fine pitch thread –Product grades A and B (*third revision*)
IS 13726 : 2023/ ISO 8765 : 2022	Hexagon head bolts with metric fine pitch thread — Product grades A and B (*third revision*)
IS 14894 : 2023/ ISO 4015 : 2022	Fasteners-Hexagon head bolts of product grade B — Reduced shank (Shank diameter ≈ Pitch diameter) — Specification (*first revision*)
IS 15274 : 2021/ ISO 4759-3 : 2016	Tolerances for fasteners – Washers for bolts, screws and nuts — Product grades A, C and F (*first revision*)
IS 15581 : 2018	Hexagon nuts with flange, style 2 — Coarse thread (*first revision*)
IS 15582 : 2018	Hexagon bolts with flange – Small series — Product grade A with driving feature of product grade B (*first revision*)
IS 15628 : 2022/ ISO 4766 : 2011	Slotted set screws with flat point — Specification (*first revision*)
IS 17445 : 2020/ ISO 15330 : 1999	Fasteners — Preloading test for the detection of hydrogen embrittlement — Parallel bearing surface method
IS 17894 : 2022/ ISO 22081 : 2021	Geometrical product specifications (GPS) –Geometrical tolerancing — General geometrical specifications and general size specifications
IS 18471 : 2025	Fasteners — Drilling screws with tapping screw thread — Specification (*first revision*)
IS 18476 : 2023	Fasteners — Hexagon washer head drilling screws with tapping screw thread
IS 18480 : 2025	Self-tapping screws — Specification (*first revision*)
IS 18507 : 2026	Drywall screws — Specification (*first revision*)
IS 18508 : 2026	Chipboard screws — Specification (*first revision*)
IS 18509 : 2024	Cross recessed countersunk head wood screws — Specification
IS 18741 : 2024	Concrete nails — Specification
IS 19078 : 2025/ ISO 10666 : 1999	Drilling screws with tapping screw thread — Mechanical and functional properties
IS 19406 : 2026/ ISO 10587 : 2000	Metallic and other inorganic coatings — Test for residual embrittlement in both metallic coated and uncoated externally threaded articles and rods — Inclined wedge method

26 TIMBER, BAMBOO AND OTHER LIGNOCELLULOSIC BUILDING MATERIALS

a) Timber and Bamboo

i) *Timber Classification*

IS No.	*Title*
IS 287 : 1993	Permissible moisture content for timber used for different purposes — Recommendations (*third revision*)
IS 399 : 1963	Classification of commercial timbers and their zonal distribution (*revised*)
IS 1150 : 2000	Trade names and abbreviated symbols *for timber species* (*third revision*)
IS 4970 : 1973	Key for identification of commercial timber (*first revision*)

ii) *Timber Conversion and Grading*

IS No.	*Title*
IS 190 : 1991	Specification for coniferous sawn timber (baulks and scantlings) (*fourth revision*)
IS 1326 : 2023	Non-Coniferous sawn timber baulks and scantling — Specification (*third revision*)
IS 1331 : 1971	Specification for cut sizes of timber (*second revision*)
IS 2377 : 1967	Tables for volumes of cut sizes of timber (*first revision*)
IS 3337 : 1978	Specification for ballies for general purposes (*first revision*)
IS 3386 : 1979	Specification for wooden fence posts (*first revision*)
IS 5966 : 2023	Non-coniferous timber in converted form for general purposes — Specification (*second revision*)
IS 14960 : 2001	Specification for preservative treated and seasoned sawn timber from rubberwood (*Hevea brasiliensis*)

iii) *Timber Testing*

IS No.	*Title*
IS 1708	Methods of testing small clear specimens of timber:
(Part 1) : 1986	Determination of moisture content (*second revision*)
(Part 2) : 1986	Determination of specific gravity (*second revision*)
(Part 3) : 1986	Determination of volumetric shrinkage (*second revision*)
(Part 4) : 1986	Determination of radial and tangential shrinkage and fibre saturation point (*second revision*)
(Part 5) : 1986	Determination of static bending strength (*second revision*)
(Part 6) : 1986	Determination of static bending strength under two point loading (*second revision*)

IS No.	*Title*
(Part 7) : 1986	Determination of impact bending strength (*second revision*)
(Part 8) : 1986	Determination of compressive strength parallel to grain (*second revision*)
(Part 9) : 1986	Determination of compressive strength perpendicular to grain (*second revision*)
(Part 10) : 1986	Determination of hardness under static indentation (*second revision*)
(Part 11) : 1986	Determination of shear strength parallel to grain (*second revision*)
(Part 12) : 1986	Determination of tensile strength parallel to grain (*second revision*)
(Part 13) : 1986	Determination of tensile strength perpendicular to grain (*second revision*)
(Part 14) : 1986	Determination of cleavage strength parallel to grain (*second revision*)
(Part 15) : 1986	Determination of nail and screw holding power (*second revision*)
(Part 16) : 1986	Determination of brittleness by izod impact (*second revision*)
(Part 17) : 1986	Determination of brittleness by charpy impact (*second revision*)
(Part 18) : 1986	Determination of torsional strength (*second revision*)
IS 2408 : 1963	Methods of static tests of timbers in structural sizes
IS 2455 : 1990	Method of sampling of model trees and logs for timber testing and their conversion (*second revision*)
IS 2753	Methods for estimation of preservatives in treated timber and treating solutions:
(Part 1) : 1991	Determination of copper, arsenic, chromium, zinc, boron, creosote and fuel oil (*first revision*)
(Part 2) : 2014	Determination of copper in copper organic preservative salt (*second revision*)
IS 4907 : 2004	Method of testing timber connector joints (*first revision*)
IS 8292 : 1992	Methods for evaluation of working quality of timber under different wood operations — Method of test (*first revision*)
IS 8720 : 1978	Methods of sampling of timber scantlings from depots and their conversion for testing
IS 8745 : 1994	Methods of presentation of data of physical and mechanical properties of timber (*first revision*)
IS 10420 : 1982	Method of determination of sound absorption coefficient of timber by standing wave method
IS 10754 : 1983	Method of determination of thermal conductivity of timber
IS 11215 : 1991	Methods for determination of moisture content of timber and timber products (*first revision*)
IS 13621 : 1993	Method of test for determination of dielectric constant of wood under microwave frequencies

iv) *Structural Timber and Test*

IS No.	*Title*
IS 2372 : 2021	Timber for cooling towers — Specification (*third revision*)
IS 3629 : 1986	Specification for structural timber in building (*first revision*)
IS 4891 : 1988	Specification for preferred cut sizes of structural timber (*first revision*)
IS 4924	Method of test for nail jointed timber trusses:
(Part 1) : 1968	Destructive test
(Part 2) : 1968	Proof test

v) *Logs*

IS No.	*Title*
IS 656 : 2023	Logs for plywood — Specification (*fourth revision*)
IS 3364	Method of measurement and evaluation of defects in timber:
(Part 1) : 1976	Logs (*first revision*)
(Part 2) : 1976	Converted timber (*first revision*)
IS 4895:1985	Specification for teak logs (*first revision*)
IS 5246:2000	Specification for coniferous logs (*first revision*)
IS 7308:1999	Specification for non-coniferous logs (*first revision*)

vi) *Bamboo*

IS No.	*Title*
IS 6874 : 2008	Method of tests for bamboos (*first revision*)
IS 8242 : 1976	Methods of tests for split bamboos
IS 17571 : 2021	Flattened bamboo board — Specification
IS 17572 : 2022	BWP grade bamboo mat-veneer composite board — Specification
IS 17573 : 2021	BWP grade bamboo mat board – Specification

(b) Reconstituted Products

i) *Plywood*

IS No.	*Title*
IS 303 : 2024	Plywood for general purposes — Specification (*fourth revision*)
IS 710 : 2024	Marine plywood — Specification (*third revision*)
IS 1328 : 2025	Veneered decorative plywood — Specification (*fourth revision*)

IS No.	*Title*
IS 1734	Methods of test for plywood:
(Part 1) : 1983	Determination of density and moisture content (*second revision*)
(Part 2) : 1983	Determination of resistance of dry heat (*second revision*)
(Part 3) : 1983	Determination of fire resistance (*second revision*)
(Part 4) : 1983	Determination of glue shear strength (*second revision*)
(Part 5) : 1983	Test for adhesion of plies (*second revision*)
(Part 6) : 1983	Determination of water resistance (*second revision*)
(Part 7) : 1983	Mycological test (*second revision*)
(Part 8) : 1983	Determination of *p*H value (*second revision*)
(Part 9) : 1983	Determination of tensile strength (*second revision*)
(Part 10) : 1983	Determination of compressive strength (*second revision*)
(Part 11) : 1983	Determination of static bending strength (*second revision*)
(Part 12) : 1983	Determination of scarf joint strength (*second revision*)
(Part 13) : 1983	Determination of panel shear strength (*second revision*)
(Part 14) : 1983	Determination of plate shear strength (*second revision*)
(Part 15) : 1983	Central loading of plate test (*second revision*)
(Part 16) : 1983	Vibration of plywood plate test (*second revision*)
(Part 17) : 1983	Long time loading test of plywood strips (*second revision*)
(Part 18) : 1983	Impact resistance test on the surface of plywood (*second revision*)
(Part 19) : 1983	Part 19 Determination of nail and screw holding power (*second revision*)
(Part 20) : 1983	Part 20 Acidity and alkalinity resistance test (*second revision*)
IS 4990 : 2024	Plywood for concrete shuttering works — Specification *(fourth revision)*
IS 5509 : 2021	Fire retardant plywood – Specification *(third revision)*
IS 5539:1969	Specification for preservative treated plywood
IS 7316:1974	Specification for decorative plywood using plurality of veneers for decorative faces
IS 10701:2012	Structural plywood — Specification (*first revision*)
IS 13957:1994	Specification for metal faced plywood
IS 15791:2007	Museum plywood — Specification

ii) *Blockboards, Particle Boards and Fibre Boards*

IS No.	*Title*
IS 1658 : 2006	Fibre hardboards — Specification (*third revision*)
IS 1659 : 2004	Block boards — Specification *(fourth revision)*
IS 2380	Methods of test for wood particle boards and boards from other lignocellulosic materials:
(Part 1) : 1977	Preparation and conditioning of test specimens (*first revision*)
(Part 2) : 1977	Accuracy of dimensions of boards (*first revision*)
(Part 3) : 1977	Determination of moisture content and density (*first revision*)
(Part 4) : 1977	Determination of static bending strength (*first revision*)
(Part 5) : 1977	Determination of tensile strength perpendicular to surface (*first revision*)
(Part 6) : 1977	Determination of tensile strength parallel to surface (*first revision*)
(Part 7) : 1977	Determination of compression-perpendicular to plane of the board (*first revision*)
(Part 8) : 1977	Compression parallel to surface test (*first revision*)
(Part 9) : 1977	Determination of resistance to shear in plane of the board (*first revision*)
(Part 10) : 1977	Falling hammer impact test (*first revision*)
(Part 11) : 1977	Surface hardness (*first revision*)
(Part 12) : 1977	Central loading of plate test (*first revision*)
(Part 13) : 1977	Long time loading bending test (*first revision*)
(Part 14) : 1977	Screw and nail withdrawal test (*first revision*)
(Part 15) : 1977	Lateral nail resistance (*first revision*)
(Part 16) : 1977	Determination of water absorption (*first revision*)
(Part 17) : 1977	Determination of swelling in water (*first revision*)
(Part 18) : 1977	Determination of mass and dimensional changes caused by moisture changes (*first revision*)
(Part 19) : 1977	Durability cyclic test for interior use (*first revision*)
(Part 20) : 1977	Accelerated weathering cyclic test for exterior use (*first revision*)
(Part 21) : 1977	Planeness test under uniform moisture content (*first revision*)
(Part 22) : 1981	Determination of surface glueability test
(Part 23) : 1981	Vibration test for particle boards
IS 3087 : 2025	Medium density particle boards of wood and other lignocellulosic materials for general purpose — Specification (*third revision*)

IS No.	*Title*
IS 3097 : 2025	Veneered medium density particle boards from wood and other lignocellulosic material — Specification (*third revision*)
IS 3129 : 1985	Specification for low density particle boards (*first revision*)
IS 3308 : 1981	Specification for wood wool building slabs (*first revision*)
IS 3348 : 1965	Specification for fibre insulation boards
IS 3478 : 1966	Specification for high density wood particle boards
IS 12406 : 2025	Medium density fibre boards of wood and other lignocellulosic materials for general purpose — Specification (*third revision*)
IS 12823 : 2025	Prelaminated medium density particle boards from wood and other lignocellulosic material — Specification (*second revision*)
IS 13745 : 2020	Method for determination of formaldehyde content in wood-based panels by extraction method called perforator method (*first revision*)
IS 14276 : 2016	Cement bonded particle boards — Specification (*first revision*)
IS 14587 : 2025	Prelaminated medium density fibre boards of wood and other lignocellulosic materials — Specification (*second revision*)
IS 15786 : 2008	Prelaminated cement bonded particle boards — Specification
IS 19267 : 2025	Oriented strand boards — Specification

iii) *Wood-Based Laminates and Lumber*

IS No.	*Title*
IS 3513	Specification for resin treated compressed wood laminates (compregs):
(Part 3) : 1989	For General Purposes (*first revision*)
(Part 4) : 1966	Sampling and tests
IS 7638 : 1999	Methods of sampling for wood/lignocellulosic based panel products
IS 9307	Methods of tests for wood-based structural sandwich construction:
(Part 1) : 1979	Flexure test
(Part 2) : 1979	Edgewise compression test
(Part 3) : 1979	Flatwise compression test
(Part 4) : 1979	Shear test
(Part 5) : 1979	Flatwise tension test
(Part 6) : 1979	Flexure creep test
(Part 7) : 1979	Cantilever vibration test
(Part 8) : 1979	Weathering test

IS No.	*Title*
IS 14315 : 1995	Specification for commercial veneers
IS 14616 : 1999	Specification for laminated veneer lumber
IS 16171 : 2014	Veneer laminated lumber – Specification

iv) *Bamboo and Coir Board Products*

IS No.	*Title*
IS 13958 : 1994	Specification for bamboo mat board for general purposes
IS 14588 : 1999	Specification for bamboo mat veneer composite for general purposes
IS 14842 : 2000	Specification for coir veneer board for general purposes
IS 15476 : 2004	Specification for bamboo mat corrugated sheets
IS 15491 : 2004	Specification for medium density coir boards for general purposes
IS 15877 : 2010	Coir faced block boards — Specification
IS 15878 : 2010	Coir hardboard for general purposes — Specification
IS 15972 : 2012	Bamboo-jute corrugated and semi-corrugated sheets — Specification

v) *Adhesives*

IS No.	*Title*
IS 848 : 2025	Synthetic resin adhesives for plywood (phenolic, aminoplastic and bio-materials based) — Specification (*third revision*)
IS 851 : 1978	Specification for synthetic resin adhesives for construction work (non-structural) in wood (*first revision*)
IS 852 : 1994	Animal glue for general wood-working purposes Specification (*second revision*)
IS 1508 : 1972	Specification for extenders for use in synthetic resin adhesives (urea-formaldehyde) for plywood (*first revision*)
IS 4835 : 1979	Specification for polyvinyl acetate dispersion-based adhesives for wood (*first revision*)
IS 9188 : 1979	Performance requirements for adhesive for structural laminated wood products for use under exterior exposure condition

27 UNIT WEIGHTS OF BUILDING MATERIALS

IS No.	*Title*
IS 875 (Part 1) : 1987	Code of practice for design loads (other than earthquake) for buildings and structures: Part 1 Dead loads — Unit weights of building material and stored materials (*second revision*)

28 WATERPROOFING AND DAMP-PROOFING MATERIALS

IS No.	*Title*
IS 1322 : 1993	Specification for bitumen felts for waterproofing and damp-proofing (*fourth revision*)

FOREWORD

This NBCS (Part C/Section 1) covers the various loads, forces and effects which are to be taken into account for structural design of buildings. The various loads that are covered under this Section are dead load, imposed load, wind load, seismic force, snow load, special loads and load combinations.

This Section was first published in 1970 and subsequently revised in 1983, 2005 and 2016 as a chapter of the National Building Code of India. The first revision of this Section was modified in 1987 through Amendment No. 2 to the 1983 version to bring this Section in line with the latest revised loading code. Thereafter, in view of the revision of an important Indian Standard related to earthquake resistant design of structures, that is IS 1893, a need arose to revise this part of NBC. Therefore, the second revision of 2005 was formulated to consider the revised standard, IS 1893 (Part 1) : 2002 ‘Criteria for earthquake resistant design of structures: Part 1 General provisions and buildings (*fifth revision*)’ and to incorporate latest information on additional loads, forces and effects and the details regarding multi-hazard risk in various districts of India.

The significant changes incorporated in the second revision of 2005 included: the revision of the seismic zone map providing only four zones, instead of five, with erstwhile Zone I being merged into Zone II; changing of the values of seismic zone factors to reflect more realistic values of effective peak ground acceleration considering maximum considered earthquake (MCE) and service life of structure in each seismic zone; specifying of response spectra for three types of founding strata, namely rock and hard soil, medium soil and soft soil; the revision of empirical expression for estimating the fundamental natural period T_a of multi-storeyed buildings with regular moment resisting frames; adoption of the procedure of first calculating the actual force that may be experienced by the structure during the probable maximum earthquake, if it were to remain elastic, also bringing in the concept of response reduction due to ductile deformation and associated energy dissipation by introducing the ‘response reduction factor’ in place of the earlier performance factor; specifying a lower bound for the design base shear of buildings, based on empirical estimate of the fundamental natural period T_a; deletion of the soil-foundation system factor and instead, introduction of a clause to restrict the use of foundations vulnerable to differential settlements in severe seismic zones; revision of torsional eccentricity values upwards in view of serious damages observed in buildings with irregular plans; revision of modal combination rule in dynamic analysis of buildings; inclusion of a new clause on multi-hazard risk in various districts of India and a list of districts identified as multi-hazard prone districts; incorporation of latest amendments issued to IS 875 introduction of a clause on vibration in buildings for general guidance; and inclusion of reference to the Indian Standards on landslide control and design of retaining walls which were formulated after the first revision of the Section.

The significant changes incorporated in the third revision of 2016 included: enhanced provisions for parapets and balustrades, incorporating concentrated horizontal loads and adjustments in horizontal load per unit length; new areas of application, such as appurtenances fixed to structures; aerodynamic roughness heights for different terrain categories were explicitly addressed, aiding in the determination of turbulence intensity and wind speed profiles; a new modification factor k_4 was introduced for cyclonic regions; simplified empirical expressions for variations in hourly mean wind speed and turbulence intensity across different terrains were suggested, along with provisions for directionality, area averaging and correlation of pressures for design wind pressure; wind-induced interference for both tall and low-rise buildings was accounted for, with recommendations for wind tunnel or CFD studies for final designs of critical structures; updates to the wind speed map of India were included; and new provisions for design loads for helipads, emergency vehicles and collisions with structural elements in parking areas. For earthquake effects, the design spectra was defined for natural periods up to 6 s, applicable to all buildings regardless of construction material; temporary structures and buildings with flat slabs were brought under the scope of the standard (though with some conditions), with guidelines for addressing structural irregularities and estimating the in-plane stiffness of masonry infill walls; additional revisions including simplified torsional provisions, methods for computing natural periods in various structures, new provisions for evaluating liquefaction potential and blast loads; and inputs were also derived from the Heliport Manual, 1995 of the International Civil Aviation Organization for the design of roof top helipad, etc.

In the current revision, this publication has been renamed as National Building Construction Standards (NBCS).

In this revision of this Part C/Section 1, load provisions have been updated in alignment with the existing IS 875 series and IS 4991. The IS 875 framework continues and the changes may be seen as its evolution. The present deterministic approach with safety margins will gradually be replaced by a unified approach of load classification and quantification. Loads will be grouped as natural or man-made and further as force-based or displacement-based. For natural hazards, return period–based probabilistic treatment will apply, while man-made loads will be based on statistical measures such as mean and standard deviation. This philosophy may, in due course, be reflected in future revisions of various Indian Standards on loading, following which their safety factors may also be recalibrated.

Further, considering the recent developments and R&D efforts nationally and internationally, the following significant modifications and inclusions have been made:

1) The provision relating to structural design basis report (SDBR) is introduced.

Dead Loads:

2) Unit weights of construction materials and stored materials have been included in Annex A.
3) Provisions relating to dead load for gardening and landscaping have been introduced.

Imposed Loads:

4) Imposed loads for dwelling units planned and executed in accordance with IS 8888 : 2020 'Requirements of low income housing for Urban areas guide (*second revision*)' have been brought at par with other residential buildings.
5) Imposed loads for datacenters have been included.
6) Imposed loads for roof top solar panels (with or without frames and with anchor blocks) and roof top HVAC equipment, have been included.
7) Imposed load for garage floors with and without stack parking have been updated.
8) Imposed load for refuge area and disaster shelter have been provided.

Wind Loads:

9) Provision relating to testing of building fabrics against wind borne debris has been included.
10) Table of basic wind speed for various cities of India has been updated.

Snow Loads:

11) A new term 'characteristic ground snow load' has been introduced and defined.
12) Characteristic ground snow load maps for union territory of Jammu and Kashmir, union territory of Ladakh and states of Himachal Pradesh, Uttarakhand and Sikkim have been introduced, resulting from studies conducted by Defence Geoinformatics Research Establishment (DRDO), Chandigarh.
13) Equation for calculation of characteristic ground snow load has been suggested in Annex H.
14) Clause relating to partial loading due to melting, sliding, snow redistribution and snow removal has been included.
15) Clause relating to ponding instability has been included.

Earthquake loads:

16) The Indian Standard IS 1893, on which the clause of earthquake load is largely based, is under revision at the time of publication of this NBCS. Major changes have been envisaged in the revision of IS 1893 which include apart from others, the introduction of probabilistic seismic hazard map of India having updated seismic zones. In the absence of availability of finalized version of revised IS 1893 at the time of revision of this Section, in this revision of the NBCS, the provisions of design as per existing IS 1893 (Part 1) : 2016 'Criteria for earthquake resistant design of structures: Part 1 General provisions and buildings' have been continued through app ropriate reference to the same.

Blast Loads:

17) Detailed provisions relating to design for blast loads have been included in Annex L. This annex provides prescriptive requirements for estimation of blast loads and simplified methods for structural analysis.
18) General requirements for blast-protection and categorization of structures have been provided.
19) Threat assessment requirements for determination of design explosive charge mass and scaled distance have been given.
20) Blast load estimation methods due to above-ground explosion of high-explosive under three different detonation scenarios: surface burst, free-air burst and air burst have been specified.
21) Evaluation of blast loads effects on structures of regular geometry and shape has been specified.
22) Prescriptive simplified single degree of freedom (SDOF) analysis procedure for peak response evaluation of structural elements based on flexural mode has been provided.
23) Guidelines for the application of multi-degree of freedom (MDOF) and detailed finite element analysis have been provided.

The provisions outlined in this Chapter are intended to assist structural designers in making informed engineering decisions when dealing with diverse loading scenarios, including special loads and unique load combinations that may arise in practical applications. It is expected that this Chapter will enable designers to adopt a rational and scientific approach in assessing structural loads and their combinations, thereby enhancing the resilience of structures against various external forces and ensuring their long-term performance. The Chapter serves as a fundamental reference for structural engineers, ensuring that the design approach aligns with safety requirements, reliability principles and advancements in engineering practices. It integrates knowledge from past experiences, research developments and international best practices while considering the specific conditions prevalent in India.

Structures are subjected to various loads, environmental effects and material degradation over time, which can impact their performance and safety. Hence, monitoring of structures has been gaining attention. Monitoring of structures is seen now along three directions, namely health monitoring, performance monitoring and safety monitoring. Structural health monitoring (SHM) involves monitoring of the condition of the materials of the structure, structural performance monitoring (SPM) involves monitoring of the response of the structure (without any damage induced in it) to daily loads the structure, such as vibrations of the structure under wind loads and structural safety monitoring involves monitoring the response of the structure when subjected to loads that damage the structure, such as, strong ground shaking of the structure during an earthquake, or air pressure induced under blast. In all cases, the engineer needs to assess the structure to identify actions needed towards repairing, correcting, protecting or retrofitting the structure, as the case be.

Monitoring of structures is a crucial process that enables the continuous or periodic assessment of structural integrity, ensuring early detection of potential damage and preventing catastrophic failures. It provides real-time insights into the behaviour of buildings and infrastructure under different conditions by utilizing advanced sensors, data acquisition systems and analytical models. The need for monitoring the structures arises from the increasing complexity of modern structures, aging infrastructure and the demand for enhanced safety and serviceability. It helps in identifying structural anomalies, degradation patterns and potential failure modes before they become critical. The system of monitoring of structures should be adopted to validate analytical models and evaluate techniques to ensure accurate assessment and decision-making. Implementing monitoring systems in buildings and structures where necessary enhances durability, reduces maintenance costs and supports proactive intervention strategies, ultimately improving structural resilience and public safety.

There has been a growing awareness among the consultants, academicians, researchers and practice engineers for design and construction of wind sensitive structures. In order to augment the available limited good quality meteorological wind data and structural response data, it is necessary to conduct full scale measurements in the field. Thus, as emphasized in the previous revision, all individuals and organizations responsible for putting-up of tall structures are encouraged to provide instrumentation in their existing and new structures at different elevations (at least at two levels) to continuously measure and monitor wind data. The instruments are required to collect data on wind direction, wind speed and structural response of the structure due to wind (with the help of accelerometer, strain gauges, etc). Such instrumentation in tall structures shall not in any way affect or alter the functional behaviour of such structures. The data so collected shall be very valuable in evolving more accurate wind loading of structures.

The information contained in this Section is largely based on the following Indian Standards:

IS 875	Code of practice for design loads (other than earthquake) for buildings and structures:
Part 1 : 2026	Dead loads-unit weights of building material and stored materials (*third revision*) (*under preparation*)
Part 2 : 1987	Imposed loads (*second revision*)
Part 3 : 2015	Wind loads (*third revision*)
Part 4 : 2021	Snow loads (*third revision*)
Part 5 : 1987	Special loads and load combinations (*second revision*)
IS 4991 (Part 1) : 2024	Criteria for blast resistant design of structures: Part 1 Above-ground explosions (*first revision*)

This Section shall be read together with Sections 2 to 8 of Part C ‘Structural Design’ of this NBCS.

A special publication, SP 64 (S&T) : 2001 ‘Explanatory Handbook on Indian Standard Code of Practice for Design Loads (Other than Earthquake) for Buildings and Structures IS 875 (Part 3) : 1987’ is also available. This publication gives detailed background information on the provisions for wind loads and the use of these provisions for arriving at the wind loads on buildings and structures while evaluating their structural safety. But, in view of revision of IS 875 (Part 3) in 2015, applicability of this revised standard and this Section of the NBCS shall be taken as final in case of conflict of provisions with SP 64.

Reference may also be made to the Vulnerability Atlas of India, 2011 and Landslide Hazard Zonation Map of India, 2003, published by Building Materials and Technology Promotion Council, Ministry of Urban Development and Poverty Alleviation, Government of India. The Vulnerability Atlas contains information pertaining to each State and Union Territory of India, on (a) seismic hazard map, (b) cyclone and wind map, (c) flood prone area map and (d) housing stock vulnerability table for each district indicating for each house type the level of risk to which it could be subjected. The Atlas can be used to identify areas in each district of the country which are prone to high risk from more than one hazard. The information will be useful in establishing the need of developing housing designs to resist the combination of such hazards.

All standards, whether given herein above or cross-referred to in the main text of this Section, are subject to revision. The parties to agreement based on this Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

As the regulation of land development and buildings is a State subject and is dealt by the States and local bodies such as urban local bodies within their jurisdiction through building regulatory documents like building regulations, building byelaws and fire regulations, this document is voluntary in nature and is non-binding. The implementation depends on adoption by concerned parties or stipulations in a contract or by appropriate adoption by the concerned authorities.

For the purpose of deciding whether a particular requirement of this section is complied with, the final value observed or calculated, expressing the result of a test or analysis, shall be rounded off in accordance with IS 2 : 2022 ‘Rules for rounding of numerical values (*second revision*)’. The number of significant places retained in the rounded off value should be the same as that of the specified value in this section.

This Page has been Intentionally left blank

Important Explanatory Note for Users of the NBCS

In any Part/Section of this NBCS, where reference is made to **'good practice'** in relation to design, constructional procedures or other related information and where reference is made to **"accepted standard"** in relation to material specification, testing, or other related information, the Indian Standards listed at the end of the Part/Section shall be used as a guide to the interpretation.

At the time of publication, the editions indicated in the standards were valid. All standards are subject to revision and parties to agreements based on any Part/ Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

In the list of standards given at the end of a Part/Section, the number appearing within parentheses in the first column indicates the number of the reference of the standard in the Part/Section. For example:

a) Good practices [C-1(1)] refers to the Indian Standard(s) give at serial number (1) of the list of standards given at the end of this Part/Section 1, that is, 8888 : 2020 'Requirements of low income housing for urban areas — Guide (second revision)'

NATIONAL BUILDING CONSTRUCTION STANDARDS

PART C STRUCTURAL DESIGN

SECTION 1 LOADS AND LOAD EFFECTS

1 SCOPE

This NBCS (Part C/Section 1) covers basic design loads to be assumed in the design of buildings. The loads specified in this section are minimum loads to be considered for design purposes in the design of buildings.

2 DEAD LOAD

2.1 Assessment of Dead Load

The dead load in a building shall comprise the weight of all walls, partitions, floors and roofs and shall include the weights of all other permanent constructions (including built-in partitions, finishes, cladding and other similarly incorporated architectural and structural items, weight of fixed service equipment) in the building.

2.2 The list of dead loads of various construction materials and stored materials are given in Annex A.

2.3 Gardening and Landscaping

Elements on roof gardening or landscaping, including soil, plants and drainage layers, along with other features like walkways, fences and walls, are fixed in place and thus classified as dead loads. While the weight of walkways, fences and walls remains constant. The weight of soil and drainage layers, which support plant growth, can vary significantly due to their ability to absorb and retain water. For load calculations, when the weight adds to other structural loads, the dead load should be based on fully saturated soil and drainage layers to account for maximum weight. If the weight is used to counteract uplift forces, calculations should assume the dry weight of soil and drainage layers. Vegetative or landscaped roof areas may retain even more water than fully saturated soil, either from rainfall or irrigation. This additional water retention should be included in the design to accurately assess load variations.

In the design calculation of overturning, uplifting and sliding effects, the beneficial effects of soil shall not be considered. When the soil is used as dead weight and locked permanently, the same may be considered.

3 IMPOSED LOAD

3.1 This clause covers imposed loads to be assumed in the design of buildings. The imposed loads specified herein are minimum loads which should be taken into consideration for the purpose of structural safety of buildings.

NOTE — This Section does not cover detailed provisions for loads incidental to construction and special cases of vibration, such as moving machinery, heavy acceleration from cranes, hoists and the like. Such loads shall be dealt with individually in each case.

3.2 Terminology

3.2.1 For the purpose of imposed loads specified herein, the following definitions shall apply:

3.2.1.1 *Assembly buildings* — These shall include any building or part of a building where groups of people congregate or gather for amusement, recreation, social, religious, patriotic, civil, travel and similar purposes; for example, theatres, motion picture houses, assembly halls, conference/meeting halls, city halls, marriage halls, town halls, auditoria, exhibition halls, museums, skating rinks, gymnasiums, restaurants (also used as assembly halls), place of worship, dance halls, club rooms, passenger stations and terminals of air, surface and other public transportation services, recreation piers and stadia, etc.

3.2.1.2 *Business buildings* — These shall include any building or part of a building, which is used for transaction of business (other than that covered by mercantile buildings); for keeping of accounts and records for similar purposes; offices, banks, professional establishments, court houses and libraries shall be classified in this group so far as principal function of these is transaction of public business and the keeping of books and records.

NOTE — The office buildings are the buildings primarily to be used as an office or for office purposes; 'office purposes' include the purpose of administration, clerical work, handling money, telephone and telegraph operating and operating computers, calculating machines, 'clerical work' includes writing, book-keeping, sorting papers, typing, filing, duplicating, drawing of matter for publication and the editorial preparation of matter for publication, etc.

3.2.1.3 *Dwellings* — These shall include any building or part occupied by members of single/multi-family units with independent cooking facilities. These shall also include apartment houses (flats).

3.2.1.4 *Educational buildings* — These shall include any building used for school, college or day-care purposes involving assembly for instruction, education or recreation and which is not covered by assembly buildings.

3.2.1.5 *Imposed load* — The load assumed to be produced by the intended use or occupancy of a building including the weight of movable partitions, distributed and concentrated loads, loads due to impact and vibration and dust loads but excluding wind, seismic, snow and other loads due to temperature changes, creep, shrinkage, differential settlement, etc.

3.2.1.6 *Industrial buildings* — These shall include any building or a part of a building or structure, in which products or materials of various kinds and properties are fabricated, assembled, manufactured or processed, for example, assembly plants, industrial laboratories, dry cleaning plants, power plants, generating units, pumping stations, fumigation chambers, laundries, buildings or structures in gas plants, refineries, dairies and saw-mills, etc.

3.2.1.7 *Institutional buildings* — These shall include any building or a part thereof, which is used for purposes such as medical or other treatment in case of persons suffering from physical and mental illness, disease or infirmity; care of infants, convalescents or aged persons and for penal or correctional detention in which the liberty of the inmates is restricted. Institutional buildings ordinarily provide sleeping accommodation for the occupants. It includes hospitals, sanatoria, custodial institutions or penal institutions like jails, prisons and reformatories.

3.2.1.8 *Occupancy or use group* — The principal occupancy for which a building or part of a building is used or intended to be used; for the purpose of classification of a building according to occupancy, an occupancy shall be deemed to include subsidiary occupancies which are contingent upon it.

3.2.1.9 *Mercantile buildings* — These shall include any building or a part of a building which is used as shops, stores, market for display and sale of merchandize either wholesale or retail. Office, storage and service and facilities incidental to the sale of merchandize and located in the same building shall be included under this group.

3.2.1.10 *Residential buildings* — These shall include any building in which sleeping accommodation is provided for normal residential purposes with or without cooking or dining or both facilities (except buildings under institutional buildings). It includes lodging or rooming houses, one or two-family private dwellings, dormitories, apartment houses (flats) and hotels.

3.2.1.11 *Storage buildings* — These shall include any building or part of a building used primarily for the storage or sheltering of goods, wares or merchandize, like warehouses, cold storages, freight depots, transit sheds, store houses, garages, hangers, truck terminals, grain elevators, barns and stables.

3.3 Imposed Loads on Floors Due to Use and Occupancy

3.3.1 *Imposed Loads*

The imposed loads to be assumed in the design of buildings shall be the greatest loads that probably will be produced by the intended use or occupancy, but shall not be less than the equivalent minimum loads specified in Table 1 subject to any reductions permitted in **3.3.2**.

Floors shall be investigated for both the uniformly distributed load (UDL) and the corresponding concentrated load specified in Table 1 and designed for the most adverse effects but they shall not be considered to act simultaneously. The concentrated loads specified in Table 1 may be assumed to act over an area of 0.3 m × 0.3 m. However, the concentrated loads need not be considered where the floors are capable of effective lateral distribution of this load.

All other structural elements shall be investigated for the effects of uniformly distributed loads on the floors specified in Table 1.

NOTES

1 Where, in Table 1, no values are given for concentrated load, it may be assumed that the tabulated distributed load is adequate for design purposes.

2 The loads specified in Table 1 are equivalent uniformly distributed loads on the plan area and provide for normal effects of impact and acceleration. They do not take into consideration special concentrated loads and other loads.

3 Where the use of an area or floor is not provided in Table 1, the imposed load due to the use and occupancy of such an area shall be determined from the analysis of loads resulting from:

a) weight of the probable assembly of persons;

b) weight of the probable accumulation of equipment and furnishing;

c) weight of the probable storage materials; and

d) impact factor, if any.

4 While selecting a particular loading, the possible change in use or occupancy of the building should be kept in view. Designers should not necessarily select in every case the lower loading appropriate to the first occupancy. In doing this they might introduce considerable restrictions in the use of the building at a later date and thereby reduce its utility.

5 The loads specified herein, which are based on estimations, may be considered as the characteristic loads for the purpose of limit state method of design till such time statistical data are established based on load surveys to be conducted in the country.

6 When an existing building is altered by an extension in height or area, all existing structural parts affected by the addition shall be strengthened where necessary and all new structural parts shall be designed to meet the requirements for building hereafter erected.

7 The loads specified in the Section does not include loads incidental to construction. Therefore, close supervision during construction is essential to ensure that overloading of the building due to loads by way of stacking of building materials or use of equipment (for example, cranes and trucks) during construction or loads which may be induced by floor to floor propping in multi-storeyed construction, does not occur. However, if construction loads were of short duration, permissible increase in stresses in the case of working stress method or permissible decrease in load factors in limit state method, as applicable to relevant design codes, may be allowed for.

8 The loads in Table 1 are grouped together as applicable to buildings having separate principal occupancy or use. For a building with multiple occupancies, the loads appropriate to the occupancy with comparable use shall be chosen from other occupancies.

9 Regarding loading on lift machine rooms including storage space used for repairing lift machines, designers should go by the recommendations of lift manufacturers for the present. Regarding loading due to false ceiling, the same should be considered as imposed loads on the roof/floor to which it is fixed.

---

[1] Where unrestricted assembly of persons is anticipated, the value of UDL should be increased to 4.0 kN/m^2.

[2] With fixed seats implies that the removal of the seating and the use of the space for other purposes is improbable. The maximum likely load in this case is, therefore, closely controlled.

[3] The loading in industrial buildings (workshops and factories) varies considerably and so three loadings under the terms 'light', 'medium' and 'heavy' are introduced in order to allow for more economical designs but the terms have no special meaning in themselves other than the imposed load for which the relevant floor is designed. It is, however important particularly in the case of heavy weight loads, to assess the actual loads to ensure that they are not in excess of 10 kN/m^2; in case where they are in excess, the design shall be based on the actual loadings.

[4] For various mechanical handling equipment which are used to transport goods, as in warehouses, workshops, store rooms, etc, the actual load coming from the use of such equipment shall be ascertained and design should cater to such loads.

3.3.1.1 *Load application*

The uniformly distributed loads specified in Table 1 shall be applied as static loads over the entire floor area under consideration or a portion of the floor area, whichever arrangement produces critical effects on the structural elements as provided in respective design codes.

In the design of floors, the concentrated loads are considered to be applied in the positions which produce the maximum stresses and where deflection is the main criterion in the positions which produce the maximum deflections. Concentrated load, when used for the calculation of bending and shear, are assumed to act at a point. When used for the calculation of local effects such as crushing or punching, they are assumed to act over an actual area of application of 0.3 m × 0.3 m.

3.3.1.2 *Loads due to light partitions*

In office and other buildings, where actual loads due to light partitions cannot be assessed at the time of planning the floors and the supporting structural members shall be designed to carry, in addition to other loads, uniformly distributed loads per square metre of not less than 33.33 percent of weight per metre run of finished partitions, subject to a minimum of 1 kN/m^2, provided total weight of partition walls per m^2 of the wall area does not exceed 1.5 kN/m^2 and the total weight per metre length is not greater than 4.0 kN.

3.3.2 *Reduction in Imposed Loads on Floors*

3.3.2.1 *For members supporting floors*

Except as provided for in 3.3.2.1(a), the following reductions in assumed total imposed loads on the floors may be made in designing columns, load bearing walls, piers, their supports and foundations:

a) No reduction shall be made for any plant or machinery which is specifically allowed for, or for buildings for storage purposes, warehouses and garages. But, for other buildings, where the floor is designed for an imposed floor load of 5.0 kN/m^2 or more, the reductions shown in **3.3.2.1** may be taken provided that the loading assumed is not less than it would have been, if all the floors had been designed for 5.0 kN/m^2 with no reductions; and

NOTE — In case, if the reduced load in the lower floor is lesser than the reduced load in the upper floor, then the reduced load of the upper floor will be adopted.

b) An example is given in Annex B illustrating the reduction of imposed loads in a multi-storeyed building in the design of column members.

Number of Floors (Including the Roof) to be Carried by Member Under Consideration	*Reduction in Total Distributed Imposed Load on All Floors to be Carried by the Member Under Consideration* Percent
1	0
2	10
3	20
4	30
5 to 10	40
Over 10	50

3.3.2.2 *For beams in each floor level*

Where a single span of beam, girder or truss supports not less than 50 m^2 of floor at one general level, the imposed floor load may be reduced in the design of the beams, girders or trusses by 5 percent for each 50 m^2 area supported subject to a maximum reduction of 25 percent. But, no reduction shall be made in any of the following types of loads:

a) Any superimposed moving load;

b) Any actual load due to machinery or similar concentrated loads;

c) The additional load in respect of partition walls; and

d) Any impact or vibration.

NOTE — The above reduction does not apply to beams, girders or trusses supporting roof loads.

3.3.3 *Posting of Floor Capacities*

Where a floor or part of a floor of a building has been designed to sustain a uniformly distributed load exceeding 3.0 kN/m^2 and in assembly, business, mercantile, industrial or storage buildings, a permanent notice in the form shown below indicating the actual uniformly distributed and/or concentrated loadings for which the floor has been structurally designed shall be posted in a conspicuous place in a position adjacent to such floor or on such part of a floor.

NOTES

1 The lettering of such notice shall be embossed or cast suitably on a tablet whose least dimension shall not be less than 0.25 m and located not less than 1.5 m above floor level with lettering of a minimum size of 25 mm.

2 If a concentrated load or a bulk load has to occupy a definite position on the floor, the same could also be indicated in the table.

DESIGNED IMPOSED FLOOR LOADING

Distributed……………..kN/m^2

Concentrated…………kN

Label Indicating Designed Imposed Floor Loading

3.4 Imposed Loads on Roofs

3.4.1 *Imposed Loads on Various Types of Roofs*

On flat roofs, sloping roofs and curved roofs, the imposed loads due to use and occupancy of the buildings and the geometry of the types of roofs shall be as given in Table 2.

Table 2 Imposed Loads on Various Types of Roofs

(*Clauses* 3.4.1 *and* 3.4.3)

Sl No. (1)	Type of Roof (2)	Imposed Load Measured on Plan Area (3)	Minimum Imposed Load Measured on Plan (4)
i)	Flat, sloping or curved roof with slopes up to and including 10 degrees		
	a) Access provided	1.5 kN/m^2	3.75 kN uniformly distributed over any span of one metre width of the roof slab and 9 kN uniformly distributed over the span of any beam or truss or wall
	b) Access not provided except for maintenance	0.75 kN/m^2	1.9 kN uniformly distributed over any span of one metre width of the roof slab and 4.5 kN uniformly distributed over the span of any beam or truss or wall
ii)	Sloping roof with slope greater than 10 degrees	For roof membrane sheets or purlins – 0.75 kN/m^2 less 0.02 kN/m^2 for every degree increase in slope over 10 degrees	Subject to a minimum of 0.4 kN/m^2
iii)	Curved roof with slope of line obtained by joining springing point to the crown with the horizontal, greater than 10 degrees	$(0.75 - 0.52\alpha^2)$ kN/m^2 where $\alpha = h/l$	Subject to a minimum of 0.4 kN/m^2

Table 2 (*Concluded*)

Sl No.	Type of Roof	Imposed Load Measured on Plan Area	Minimum Imposed Load Measured on Plan
(1)	(2)	(3)	(4)
		h = height of the highest point of the structure measured from its springing; and l = chord width of the roof if singly curved and shorter of the two sides if doubly curved. Alternatively, where structural analysis can be carried out for curved roofs of all slopes in a simple manner applying the laws of statistics, the curved roofs shall be divided into minimum 6 equal segments and for each segment imposed load shall be calculated appropriate to the slope of the chord of each segment as given in (i) and (ii).	

NOTES

1 The loads given above do not include loads due to snow, rain, dust collection, etc. The roof shall be designed for imposed loads given above or for snow/rain load, whichever is greater.

2 For special types of roofs with highly permeable and absorbent material, the contingency of roof material increasing in weight due to absorption of moisture shall be provided for.

Roofs of buildings used for promenade or incidental to assembly purposes shall be designed for the appropriate imposed floor loads given in Table 1 for the occupancy.

3.4.2 *Concentrated Load on Roof Coverings*

To provide for loads incidental to maintenance, unless otherwise specified by the Engineer-in-Charge, all roof coverings (other than glass or transparent sheets made of fibre glass) shall be capable of carrying an incidental load of 0.90 kN concentrated on an area of 1 250 mm^2 so placed as to produce maximum stresses in the covering. The intensity of the concentrated load may be reduced with the approval of the Engineer-in-Charge, where it is ensured that the roof coverings would not be traversed without suitable aids. In any case, the roof coverings shall be capable of carrying the loads in accordance with **3.4.1**, **3.4.3** and **3.4.4** and wind load.

3.4.3 *Loads Due to Rain*

On surfaces whose positioning, shape and drainage system are such as to make accumulation of rain water possible, loads due to such accumulation of water and the imposed loads for the roof as given in Table 2 shall be considered separately and the more critical of the two shall be adopted in the design.

3.4.4 *Dust Loads*

In areas prone to settlement of dust on roofs (example, steel plants, cement plants), provision for dust load equivalent to probable thickness of accumulation of dust may be made.

3.4.5 *Loads on Members Supporting Roof Coverings*

Every member of the supporting structure which is directly supporting the roof covering(s) shall be designed to carry the more severe of the following loads except as provided in **3.4.5.1**:

a) The load transmitted to the members from the roof covering(s) in accordance with **3.4.1**, **3.4.3** and **3.4.4**; and

b) An incidental concentrated load of 0.90 kN concentrated over a length of 125 mm placed at the most critical positions on the member.

NOTE — Where it is ensured that the roofs would be traversed only with the aid of planks and ladders capable of distributing the loads on them to two or more supporting members, the intensity of concentrated load indicated in **3.4.5**(**b**) may be reduced to 0.5 kN with the approval of the Engineer-in-Charge.

3.4.5.1 In case of sloping roofs with slope greater than 10º, members supporting the roof purlins, such as trusses, beams, girders, etc, may be designed for two-thirds of the imposed load on purlin or roofing sheets.

3.5 Imposed Horizontal Loads on Parapets, Balustrades and Other Appurtenances Fixed to Structure and on Grandstands

3.5.1 *Parapets, Parapet Walls, Balustrades and other Appurtenances Fixed to the Structure such as Grab Bars, Fixed Ladders and Guardrails in Stilt Parking*

Parapets, parapet walls, balustrades and other appurtenances fixed to the structure such as grab bars, fixed ladders and guardrails in stilt parking, together with the members which give them structural support, shall be designed for the minimum loads given in Table 3. These are expressed as horizontal forces acting at handrail or coping level. These loads shall be considered to act vertically also but not simultaneously with the horizontal forces. The values given in Table 3 are minimum values and where values for actual loadings are available, they shall be used instead.

Table 3 Horizontal Loads on Parapets, Parapet Walls and Balustrades

(*Clause* 3.5.1)

Sl No. (1)	**Usage Area** (2)	**Intensity of Horizontal Load** kN/m Run (3)	**Concentrated Load (For each 3 m Length)** kN (4)
i)	Light access stairs, gangways and like, not more than 600 mm wide	0.25	—
ii)	Light access stairs, gangways and like, more than 600 mm wide; stairways, landings, balconies and parapet walls (private and part of dwellings)	0.35	—
iii)	a) All other stairways, landings and balconies and all parapets and handrails to roofs [except those subject to overcrowding covered under (iv)]	0.75	0.89
	b) Panel fillers	0.20	0.22

Table 3 (*Concluded*)

Sl No. (1)	Usage Area (2)	**Intensity of Horizontal Load** kN/m Run (3)	**Concentrated Load (For each 3 m Length)** kN (4)
iv)	Parapets and balustrades:		
	a) In places of assembly, such as restaurants and bars, retail and public areas, not likely to be overcrowded	1.5	1.5
	b) In places of assembly, such as retail areas, theatres, cinemas, bars, auditoria, shopping malls, discothèques, places of worship, likely to be overcrowded	3.0	1.5
v)	Grab bars	—	1.11
vi)	Fixed ladders	—	1.33
vii)	Guardrail systems and handrail assemblies	0.73	0.89

NOTE — In the case of guard parapets on a floor of multi-storeyed car park or crash barriers provided in certain buildings for fire escape, the value of imposed horizontal load (together with impact load) may be determined. For (vii), this load need not be considered for (a) one- and two- family dwellings and (b) factory, industrial and storage occupancies, in areas that serve occupant load not greater than 22 kN.

3.5.2 *Grandstands and the Like*

Grandstands, stadia, assembly platforms, reviewing stands and the like shall be designed to resist a horizontal force applied to seats of 0.35 kN per linear metre along the line of seats and 0.15 kN per linear metre perpendicular to the line of the seats. These loadings need not be applied simultaneously. Platforms without seats shall be designed to resist a minimum horizontal force of 0.25 kN/m^2 of plan area.

3.6 Loading Effects Due to Impact and Vibration

The crane loads to be considered under imposed loads shall include the vertical loads, eccentricity effects induced by vertical loads, impact factors, lateral and longitudinal braking forces acting across and along the crane rails, respectively.

3.6.1 *Impact Allowance for Lifts, Hoists and Machinery*

The imposed loads specified in 3.3.1 shall be assumed to include adequate allowance for ordinary impact conditions. However, for structures carrying loads which induce impact or vibration, as far as possible, calculations shall be made for increase in the imposed load due to impact or vibration. In the absence of sufficient data for such calculation, the increase in the imposed loads shall be as follows:

	Structures	*Impact Allowance* Percent *Min*
a)	For frames supporting lifts and hoists	100
b)	For foundations, footings and piers supporting lifts and hoisting apparatus	40
c)	For supporting structures and foundations for light machinery, shaft or motor units	20
d)	For supporting structures and foundations for reciprocating machinery or power units	50

3.6.2 *Concentrated Imposed Loads with Impact and Vibration*

3.6.2.1 Concentrated imposed loads with impact and vibration which may be due to installed machinery shall be considered and provided for in the design. The impact factor shall not be less than 20 percent which is the amount allowable for light machinery.

3.6.2.2 Provision shall also be made for carrying any concentrated equipment loads while the equipment is being installed or moved for servicing and repairing.

3.6.3 *Impact Allowance for Crane Girders*

For crane gantry girders and supporting columns, the impact allowances (given below) shall be deemed to cover all forces set up by vibration, shock from slipping of slings, kinetic action of acceleration and retardation and impact of wheel loads.

	Type of Load	*Additional Load*
a)	Vertical loads for electric overhead cranes	25 percent of maximum static loads for crane girders for all class of cranes 25 percent for columns supporting Class III and Class IV cranes 10 percent for columns supporting Class I and Class II cranes No additional load for design of foundations
b)	Vertical loads for hand operated cranes	10 percent of maximum wheel loads for crane girders only
c)	Horizontal forces transverse to rails:	
	1) For electric overhead cranes with trolley having rigid mast for suspension of lifted weight (such as soaker crane, stripper crane, etc)	10 percent of weight of crab and the weight lifted by the cranes, acting on any one crane track rail, acting in either direction and equally distributed amongst all the wheels on one side of rail track For frame analysis, this force, calculated as above, shall be applied on one side of the frame at a time in either direction
	2) For all other electric overhead cranes and hand operated cranes	5 percent of weight of crab and the weight lifted by the cranes, acting on any one crane track rail, acting in either direction and equally distributed amongst the wheels on one side of rail track For the frame analysis, the force, calculated as above, shall be applied on one side of the frame at a time in either direction

	Type of Load	*Additional Load*
d)	Horizontal traction forces along the rails for overhead cranes, either electrically operated or hand operated	5 percent of all static wheel loads

Forces specified in (c) and (d) shall be considered as acting at the rail level and being appropriately transmitted to the supporting system. Gantry girders and their vertical supports shall be designed on the assumption that either of the horizontal forces in (c) and (d) may act at the same time as the vertical load.

NOTE — *See* as per good practice [C-1(2)] for classification (Class I to Class IV) of cranes.

3.6.3.1 *Overloading factors in crane supporting structures*

For all ladle cranes and charging cranes where there is possibility of overloading from production considerations, an overloading factor of 10 percent of the maximum wheel loading shall be taken.

3.6.4 *Crane Load Combinations*

In the absence of any specific indications, the load combinations shall be as indicated below.

3.6.4.1 *Vertical loads*

In an aisle, where more than one crane is in operation or has provision for more than one crane in future, the following load combinations shall be taken for vertical loading:

a) two adjacent cranes working in tandem with full load and with overloading according to **3.6.3.1**; and

b) for long span gantries, where more than one crane can come in the span, the girder shall be designed for one crane fully loaded with overloading according to **3.6.3.1** plus as many loaded cranes as can be accommodated on the span but without taking into account overloading according to **3.6.3**(**a**) to give the maximum effect.

3.6.4.2 *Lateral surge*

For design of columns and foundations, supporting crane girders, the following crane combinations shall be considered:

a) *For single bay frames* — Effect of one crane in the bay giving the worst effect shall be considered for calculation of surge force; and

b) *For multi-bay frames* — Effect of two cranes working, one each in any of two bays in the cross section to give the worst effect shall be considered for calculation of surge force.

3.6.4.3 *Tractive force*

3.6.4.3.1 Where one crane is in operation with no provision for future crane, tractive force from only one crane shall be taken.

3.6.4.3.2 Where more than one crane is in operation or there is provision for future crane, tractive force from two cranes giving maximum effect shall be considered.

NOTE — Lateral surge force and longitudinal tractive force acting across and along the crane rail respectively shall not be assumed to act simultaneously. However, if there is only one crane in the bay, the lateral and longitudinal forces may act together simultaneously with vertical loads.

3.7 Rooftop Helipad

Elevated helipad structures shall be designed as per the latest guidelines of Directorate General of Civil Aviation and International Civil Aviation Organization’s Heliport Manual.

3.7.1 *Structural Design*

Elevated helipads may be designed for a specific helicopter type though greater operational flexibility will be obtained from a classification system of design. The final approach and take-off area (FATO) should be designed for the largest or heaviest type of helicopter that is anticipated to use the helipad and account taken of other types of loading such as personnel, freight, snow, refueling equipment, etc. For the purpose of design, it is to be assumed that the helicopter will land on two main wheels, irrespective of the actual number of wheels in the undercarriage, or on two skids, if they are fitted. The loads imposed on the structure should be taken as point loads at the wheel centres as shown below:

Sl No.	*Helicopter Category*	*Maximum Take-off Mass*		*Point Load for Each Wheel*	*Under-Carriage Wheel Centres*	*Super-imposed Load* S_{Ha}	*Super-imposed Load* S_{Hb}
		kg	kN	kN	M	kN/m^2	kN/m^2
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
i)	1	Up to 2300	Up to 22.6	12.0	1.75	0.5	1.5
ii)	2	2 301 to 5000	22.6 to 49.2	25.0	2.0	0.5	2.0
iii)	3	5001 to 9000	49.2 to 88.5	45.0	2.5	0.5	2.5
iv)	4	9001 to 13500	88.5 to 133.0	67.0	3.0	0.5	3.0
v)	5	13501 to 19500	133.0 to 192.0	96.0	3.5	0.5	3.0
vi)	6	19501 to 27000	192.0 to 266.0	133.0	4.5	0.5	3.0

3.7.2 The FATO should be designed for the worse condition derived from consideration of the following two cases.

3.7.3 *Case A — Helicopter on Landing*

When designing a FATO on an elevated helipad and in order to cover the bending and shear stresses that result from a helicopter touching down, the following should be taken into account:

a) *Dynamic load due to impact on touchdown* — This should cover the normal touchdown, with a rate of descent of 1.8 m/s, which equates to the serviceability limit state. The impact load is then equal to 1.55 times the maximum take-off mass of the helicopter;

   The emergency touchdown should also be covered at a rate of descent of 3.6m/s (12 ft/s), which equates to the ultimate limit state. The partial safety factor in this case should be taken as 1.66. Therefore,
   Ultimate design load = 1.66 × service load

   = (1.66 × 1.5) maximum take-off mass

   = 2.5 maximum take-off mass

   The sympathetic response factor discussed at 3.7.3(b) below should be applied.

b) *Sympathetic response on the FATO* — The dynamic load should be increased by a structural response factor dependent upon the natural frequency of the platform slab when considering the design of supporting beams and columns. This increase in loading will usually apply only to slabs with one or more freely supported edges. It is recommended that the average structural response factor (R) of 1.3 should be used in determining the ultimate design load;

c) *Over-all superimposed load on the FATO* (S_{Ha}) — To allow for snow load, personnel, freight and equipment loads, etc, in addition to wheel loads, an allowance of 0.5 KN/m^2 should be included in the design;

d) *Lateral load on the platform supports* — The supports of the platform should be designed to resist a horizontal point load equivalent to 0.5 maximum take-off mass of the helicopter, together with the wind loading [*see* (*f*)], applied in the direction which will provide the greater bending moments;

e) *Dead load of structural members* — The partial safety factor to be used for the dead load should be taken as 1.4;

f) *Wind loading* — Shall be as per 4; and

g) *Punching shear* — Check for the punching shear of an undercarriage wheel or skid using the ultimate design load with a contact area of 64.5×10^3 mm^2.

3.7.4 *Case B — Helicopter at Rest*

When designing a FATO on an elevated helipad and in order to cover the bending and shear stresses from a helicopter at rest, the following should be taken into account:

a) *Dead load of the helicopter* — Each structural element must be designed to carry the point load, in accordance with the table under 3.7.1, from the two main wheels or skids applied simultaneously in any position on the FATO so as to produce the worst effect from both bending and shear;

b) *Over-all superimposed load* (S_{Hb}) — In addition to wheel loads, an allowance for over-all superimposed load given in the table under 3.7.1, over the area of the FATO, should be included in the design; and

c) *Dead load on structural members and wind loading* — The same factors should be included in the design for these items as given for Case A.

NOTE — The above design loads for helicopters at rest are summarized below:

Design Load for Helicopter on Landing — Case A

i) *Superimposed loads*	
a) Helicopter	2.5 L_H distributed as two point loads at the wheel centres for the helicopter category given in the informal table under 3.7.1. Average value for R = 1.3.
b) Lateral load	$1.6\ \frac{L_H}{2}$ applied horizontally in any direction.
c) Over-all superimposed load	Load at platform level together with the maximum wind loading. 1.4 S_{Ha} over the whole area of the platform (S_{Ha} given in the informal table under 3.7.1).
ii) Dead load	$1.4G$
iii) Wind loading	$1.4W$
iv) Punching shear check	2.5 $L_H R$ load over tyre skid contact area of 64.5×10^3 mm^2.

Design Load For Helicopter at Rest — Case B

i) *Superimposed loads*	
a) Helicopter	1.6 L_H distributed as two point loads at the wheel centres for the helicopter category given in the informal table under **3.7.1**.
b) Over-all superimposed load (Personnel, freight, etc)	1.6 S_{Hb} over the whole area of the platform. S_{Hb} given in the informal table under **3.7.1**.
ii) Shear check	Check as appropriate

Symbol	*Meaning*
L_H	Maximum take-off mass of helicopter
G	Dead load of structure
W	Wind loading
R	Structural response factor
S_{Ha}	Superimposed load — Case A
S_{Hb}	Superimposed load — Case B

Load Type	*Partial Load Factors*
Dynamic load (ultimate design load)	2.5
Imposed load	1.6
Dead load	1.4
Wind loading	1.4

3.7.5 Normally, the upper load limit of the selected helicopter category should be used for design purposes; however, to avoid over-design, the upper limit in any band may be exceeded by up to 10 percent if the maximum take-off mass of a helicopter falls just into the next higher category.

3.8 Fire Tenders and Emergency Vehicles

Where a structure or portions of a structure are accessed and loaded by fire department access vehicles and other similar emergency vehicles, the structure shall be designed for the greater of the following loads:

a) the actual operational loads, including outrigger reactions and contact areas of the vehicles as stipulated and provided by the building official;

b) the contact area of wheel dimensions to be used considering 45° distribution at the reinforcement of slab considering the bear coat on the slab and any soil filling.

or

in absence of any data, the bare slab loading may be considered as 15 kN/m^2 to 20 kN/m^2.

c) when the fire tender load is combined with gravity loads and the same can be considered as accidental load with the partial load factor of 1.05; and

d) fire tender load need not be combined with lateral loads.

4 WIND LOAD

4.1 General

4.1.1 This clause gives wind forces and their effects (static and dynamic) that should be taken into account when designing buildings, structures and components thereof.

4.1.2 Wind speeds vary randomly both in time and space and hence assessment of wind loads and response predictions are very important in the design of several buildings and structures. A large majority of structures met with in practice do not however, suffer wind induced oscillations and generally do not require to be examined for the dynamic effects of wind. For such normal, short and heavy structures, estimation of loads using static wind analysis has proved to be satisfactory. The details of this method involving important wind characteristics such as the basic wind speeds, terrain categories, modification factors, wind pressure and force coefficients, etc, are given in **4.4** and **4.5**.

4.1.3 Nevertheless, there are various types of structures or their components such as some tall buildings which require investigation of wind induced oscillations. The influence of dynamic velocity fluctuations on the along wind loads (drag loads) for these structures shall be determined using Gust Factor Method, included in **4.8**. A method for calculation of across wind response of tall buildings is included in **4.8.3**.

4.1.4 This Section also applies to buildings or other structures during erection/construction and the same shall be considered carefully during various stages of erection/construction. In locations where the strongest winds and icing may occur simultaneously, loads on structural members, cables and ropes shall be calculated by assuming an ice covering based on climatic and local experience.

4.1.5 Wind is air in motion relative to the surface of the earth. The primary cause of wind is traced to earth's rotation and differences in terrestrial radiation. The radiation effects are primarily responsible for convection either upwards or downwards. The wind generally blows horizontal to the ground at high wind speeds. Since vertical components of atmospheric motion are relatively small, the term ‘wind’ denotes almost exclusively the horizontal wind; vertical winds are always identified as such. The wind speeds are assessed with the aid of anemometers or anemographs which are installed at meteorological observatories at heights generally varying from 10 m to 30 m above ground.

4.1.6 Very strong winds (more than 80 km/h) are generally associated with cyclonic storms, thunderstorms, dust storms or vigorous monsoons. A feature of the cyclonic storms over the Indian area is that they rapidly weaken after crossing the coasts and move as depressions/lows inland. The influence of a severe storm after striking the coast does not; in general exceed about 60 km, though sometimes, it may extend even up to 120 km. Very short duration hurricanes of very high wind speeds called Kal Baisaki or Norwesters occur fairly frequently during summer months over North East India.

4.1.7 The wind speeds recorded at any locality are extremely variable and in addition to steady wind at any time, there are effects of gusts which may last for a few seconds. These gusts cause increase in air pressure but their effect on stability of the building may not be so important; often, gusts affect only part of the building and the increased local pressures may be more than balanced by a momentary reduction in the pressure elsewhere. Because of the inertia of the building, short period gusts may not cause any appreciable increase in stress in main components of the building although the walls, roof sheeting and individual cladding units (glass panels) and their supporting members such as purlins, sheeting rails and glazing bars may be more seriously affected. Gusts can also be extremely important for design of structures with high slenderness ratios.

4.1.8 The liability of a building to high wind pressures depends not only upon the geographical location and proximity of other obstructions to air flow but also upon the characteristics of the structure itself.

4.1.9 The effect of wind on the structure as a whole is determined by the combined action of external and internal pressures acting upon it. In all cases, the calculated wind loads act normal to the surface to which they apply.

4.1.10 The stability calculations as a whole shall be done considering the combined effect, as well as separate effects of imposed loads and wind loads on vertical surfaces, roofs and other part of the building above general roof level.

4.1.11 Buildings shall also be designed with due attention to the effects of wind on the comfort of people inside and outside the buildings.

4.1.12 Wind borne debris present in cyclone or high speed wind has been causing a significant amount of damage to building envelopes. The actual in-service performance of fenestration assemblies and impact protective systems in areas prone to severe high speed wind depends on many factors. The main factors that affect the actual loading on building surfaces during a severe windstorm include varying wind direction, duration of the wind event, height above ground, building shape, terrain and surrounding structures. The resistance of fenestration or protective systems assemblies to wind loading after impact depends upon the product design, installation, load magnitude, duration and repetition. The method for determination of performance relating to safety of external building envelope like glazed curtain walls, exterior doors, exterior windows, impact protective systems (shutters, screens), skylight, wall cladding system, etc, impacted by wind borne debris, for buildings and other structures located in geographic regions that are prone to cyclone or extreme wind events shall be in accordance with [C-1(3)].

NOTES

1 This Section does not apply to buildings or structures with unconventional shapes, unusual locations and abnormal environmental conditions that have not been covered in this NBCS. Special investigations are necessary in such cases to establish wind loads and their effects. Wind tunnel studies may also be required in such situations.

2 In the case of tall structures with unsymmetrical geometry, the designs may have to be checked for torsional effects due to wind pressure.

3 The provisions given in good practice [C-1(4)] may be suitably referred by the design engineer/planner for reference.

4.2 Notations

The notations to be followed unless otherwise specified in relevant clauses under wind loads are given in **C-1**.

4.3 Terminology

4.3.1 For the purpose of wind loads, the following definitions shall apply.

4.3.1.1 *Angle of attack* — An angle between the direction of wind and a reference axis of the structure.

4.3.1.2 *Breadth* — It means horizontal dimension of the building measured normal to the direction of wind.

4.3.1.3 *Depth* — It means the horizontal dimension of the building measured in the direction of the wind.

NOTE — Breadth and depth are dimensions measured in relation to the direction of wind, whereas length and width are dimensions related to the plan.

4.3.1.4 *Developed height* — It is the height of upward penetration of the velocity profile in a new terrain. At large fetch lengths, such penetration reaches the gradient height, above which the wind speed may be taken to be constant. At lesser fetch lengths, a velocity profile of a smaller height but similar to that of the fully developed profile of that terrain category has to be taken, with the additional provision that the velocity at the top of this shorter profile equal to that of the un-penetrated earlier velocity profile at that height.

4.3.1.5 *Effective frontal area* — The projected area of the structure normal to the direction of wind.

4.3.1.6 *Element of surface area* — The area of surface over which the pressure coefficient is taken to be constant.

4.3.1.7 *Force coefficient* — A non-dimensional coefficient such that the total wind force on a body is the product of the force coefficient, the dynamic pressure of the incident design wind speed and the reference area over which the force is required.

NOTE — When the force is in the direction of the incident wind, the non-dimensional coefficient will be called as 'drag coefficient'. When the force is perpendicular to the direction of incident wind, the non-dimensional coefficient will be called as 'lift coefficient'.

4.3.1.8 *Ground roughness* — The nature of the earth's surface as influenced by small scale obstructions such as trees and buildings (as distinct from topography) is called ground roughness.

4.3.1.9 *Gust* — A positive or negative departure of wind speed from its mean value, lasting for not more than, say, 2 min over a specified interval of time.

4.3.1.10 *Peak gust* — A peak gust or peak gust speed is the wind speed associated with the maximum amplitude.

4.3.1.11 *Fetch length* — It is the distance measured along the wind from a boundary at which a change in the type of terrain occurs. When the changes in terrain types are encountered (such as, the boundary of a town or city, forest, etc), the wind profile changes in character but such changes are gradual and start at ground level, spreading or penetrating upwards with increasing fetch length.

4.3.1.12 *Gradient height* — It is the height above the mean ground level at which the gradient wind blows as a result of balance among pressure gradient force, Coriolis force and centrifugal force. For the purpose of this Section, the gradient height is taken as the height above the mean ground level, above which the variation of wind speed with height need not be considered.

4.3.1.13 *Tall building* — A building with a height more than or equal to 50 m or having a height to smaller lateral dimension more than 6.

4.3.1.14 *Low rise building* — A building having its height less than 20 m.

4.3.1.15 *Mean ground level* — The mean ground level is the average horizontal plane of the area enclosed by the boundaries of the structure.

4.3.1.16 *Pressure coefficient* — It is the ratio of the difference between the pressure acting at a point on the surface and the static pressure of the incident wind to the design wind pressure, where the static and design wind pressures are determined at the height of the point considered after taking into account the geographical location, terrain conditions and shielding effect. The pressure coefficient is also equal to $[1 - (V_p/V_z)^2]$, where V_p is the actual wind speed at any point on the structure at a height corresponding to that of V_z.

NOTE — Positive sign of the pressure coefficient indicates pressure acting towards the surface and negative sign indicates pressure acting away from the surface.

4.3.1.17 *Return period* — It is the number of years, reciprocal of which gives the probability of extreme wind exceeding a given wind speed in anyone year.

4.3.1.18 *Shielding effect* — Shielding effect or shielding refers to the condition where wind has to pass along some structure(s) or structural element(s) located on the upstream wind side, before meeting the structure or structural element under consideration. A factor called ‘shielding factor’ is used to account for such effects in estimating the force on the shielded structures.

4.3.1.19 *Suction* — It means pressure less than the atmospheric (static) pressure and is taken to act away from the surface.

4.3.1.20 *Solidity ratio* — It is equal to the effective area (projected area of all the individual elements) of a frame normal to the wind direction divided by the area enclosed by the boundary of the frame normal to the wind direction.

NOTE — Solidity ratio is to be calculated for individual frames.

4.3.1.21 *Terrain category* — It means the characteristics of the surface irregularities of an area which arise from natural or constructed features. The categories are numbered in increasing order of roughness.

4.3.1.22 *Topography* — The nature of the earth's surface as influenced by the hill and valley configurations.

4.3.1.23 *Velocity profile* — The variation of the horizontal component of the atmospheric wind speed at different heights above the mean ground level is termed as velocity profile.

4.4 Wind Speed

4.4.1 *Nature of Wind in Atmosphere*

In general, wind speed in the atmospheric boundary layer increases with height from zero at ground level to maximum at a height called the gradient height. There is usually a slight change in direction (Ekman effect) but this is ignored in this Section. The variation with height depends primarily on the terrain conditions. However, the wind speed at any height never remains constant and it has been found convenient to resolve its instantaneous magnitude into an average or mean value and a fluctuating component around this average value. The average value depends on the average time employed in analyzing the meteorological data and this averaging time varies from few seconds to several minutes. The magnitude of fluctuating component of the wind speed, which is called gust, depends on the averaging time. In general, smaller the averaging interval more is the magnitude of the gust speed.

4.4.2 *Basic Wind Speed*

Figure 1 gives basic wind speed map of India, as applicable to 10 m height above mean ground level for different zones of the country. Basic wind speed is based on peak gust velocity averaged over a short time interval of about 3 s and corresponds to mean heights above ground level in an open terrain (Category 2). Basic wind speeds presented in Fig. 1 have been worked out for a 50 year return period. Basic wind speed for some important cities/towns is also given in Annex D.

4.4.3 *Design Wind Speed* (V_z)

The basic wind speed (V_b) for any site shall be obtained from Fig. 1 and shall be modified to include the following effects to get design wind speed, V_z at any height z, for the chosen structure:

a) Risk level;

b) Terrain roughness and height of structure;

c) Local topography; and

d) Importance factor for the cyclonic region.

It can be mathematically expressed as follows:

$$V_z = V_b\, k_1\, k_2\, k_3\, k_4$$

where

V_z = design, in m/s, wind speed at height z;

k_1 = probability factor (risk coefficient) (*see* **4.4.3.1**);

k_2 = terrain roughness and height factor (*see* **4.4.3.2**);

k_3 = topography factor (*see* **4.4.3.3**); and

k_4 = importance factor for the cyclonic region (*see* **4.4.3.4**).

NOTE — Wind speed may be taken as constant up to a height of 10 m. However, pressures for buildings less than 10 m high may be reduced by 20 percent for evaluating stability and design of the framing.

4.4.3.1 *Risk coefficient* (k_1 factor)

Figure 1 gives basic wind speeds for terrain Category 2 as applicable at 10 m above ground level based on 50 years mean return period. The suggested life period to be assumed in design and the corresponding k_1 factors for different class of structures for the purpose of design are given in Table 4. In the design of buildings and structures, a regional basic wind speed having a mean return period of 50 years shall be used except as specified in the Note of Table 4.

4.4.3.2 *Terrain, height factor* (k_2 factor)

4.4.3.2.1 *Terrain*

Selection of terrain categories shall be made with due regard to the effect of obstructions which constitute the ground surface roughness. The terrain category used in the design of a structure may vary depending on the direction of wind under consideration. Wherever sufficient meteorological information is available about the nature of wind direction, the orientation of any building or structure may be suitably planned.

Terrain in which a specific structure stands shall be assessed as being one of the following terrain categories:

a) *Category* 1 — Exposed open terrain with few or no obstructions and in which the average height of any

The territorial waters of India extend into the sea to a distance of twelve nautical miles measured from the appropriate baseline.

The interstate boundaries between Arunachal Pradesh, Assam and Meghalaya shown on this map are as interpreted from the North-Eastern Areas (Reorganization) Act, 1971, but have yet to be verified.

The external boundaries and coastlines of India agree with the Record/Master Copy certified by Survey of India.

The responsibility for the correctness of internal details rest with the publisher.

NOTES

1 The occurrence of a tornado is possible in virtually any part of India. They are particularly more severe in the northern parts of India. The recorded number of these tornados is too small to assign any frequency. The devastation caused by a tornado is due to exceptionally high winds about its periphery, and the sudden reduction in atmospheric pressure at its centre, resulting in an explosive outward pressure on the elements of the structure. the regional basic wind speeds do not include any specific allowance for tornados. It is not the usual practice to allow for the effect of tornados unless special requirements are called for as in the case of important structures such as, nuclear power reactors and satellite communication towers.

2 The total number of cyclonic storms that have struck different sections of east and west coasts are included in Fig. 1, based on available records for the period from 1877 to 1982. The figures above the lines (between the stations) indicate the total number of severe cyclonic storms with or without a core of hurricane winds (speeds above 87 km/h) and the figures in the brackets below the lines indicate the total number of cyclonic storms. Their effect on land is already reflected in the basic wind speeds specified in Fig. 1. These have been included only as additional information.

FIG. 1 BASIC WIND SPEED IN m/s (BASED ON 50-YEARS RETURN PERIOD)

object surrounding the structure is less than 1.5 m. The equivalent aerodynamic roughness height, ($z_{0,1}$) for this terrain is 0.002 m. Typically this category represents open sea-coasts and flat plains without trees;

b) *Category* 2 — Open terrain with well scattered obstructions having heights generally between 1.5 m and 10 m. The equivalent aerodynamic roughness height, ($z_{0,2}$) for this terrain is 0.02 m. This is the criterion for measurement of regional basic wind speeds and represents airfields, open park lands and undeveloped sparsely built-up outskirts of towns and suburbs. Open land adjacent to sea coast may also be classified as Category 2 due to roughness of large sea waves at high winds;

c) *Category* 3 — Terrain with numerous closely spaced obstructions having the size of buildings/structures up to 10 m in height with or without a few isolated tall structures. The equivalent aerodynamic roughness height, ($z_{0,3}$) for this terrain is 0.2 m. This category represents well wooded areas and shrubs, towns and industrial areas full or partially developed. It is likely that the, next higher category than this will not exist in most design situations and that selection of a more severe category will be deliberate; and

d) *Category* 4 — Terrain with numerous large high closely spaced obstructions. The equivalent aerodynamic roughness height, ($z_{0,4}$) for this terrain is 2.0 m. This category represents large city centres, generally with obstructions above 25 m and well developed industrial complexes.

Table 4 Risk Coefficients for Different Classes of Structures in Different Wind Speed Zones

(*Clause* 4.4.3.1)

Sl No.	**Class of Structure**	**Mean Probable Design Life of Structure in Years**	**k_1 Factor for Basic Wind Speed** (in m/s) **of**					
			33	39	44	47	50	55
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)
i)	All general buildings and structures and ground based free standing tower up to 50 m	50	1.0	1.0	1.0	1.0	1.0	1.0
ii)	Temporary sheds, structures such as those used during construction operations (for example forL-work and false work), structures during construction stages and boundary walls	5	0.82	0.76	0.73	0.71	0.70	0.67
iii)	Buildings and structures presenting a low degree of hazard to life and property in the event of failure, such as isolated towers in wooded areas, farm buildings other than residential buildings	25	0.94	0.92	0.91	0.90	0.90	0.89
iv)	Important buildings and structures, such as hospitals, communication buildings/towers and power plant structures	100	1.05	1.06	1.07	1.07	1.08	1.08

NOTE — The factor k_1 is based on statistical concepts which take into account the degree of reliability required and period of time in years during which there will be exposure to wind, that is, life of the structure. Whatever wind speed is adopted for design purposes, there is always a probability (however small) that it may be exceeded in a storm of exceptional violence; more the period of years over which there is exposure to the wind, more is the probability. Larger return periods ranging from 100 to 1 000 years (implying lower risk level) in association with larger periods of exposure may have to be selected for exceptionally important structures, such as, nuclear power reactors and satellite communication towers. Equation given below may be used in such cases to estimate k_1 factors for different periods of exposure and chosen probability of exceedance (risk level). The probability level of 0.63 is normally considered sufficient for design of buildings and structures against wind effects and the values of k_1 corresponding to this risk level are given above.

Table 4 (*Concluded*)

$$k_1 = \frac{X_{\mathrm{N,P}}}{X_{50,0.63}} = \frac{A - B\left[l_n\left\{-\frac{1}{N}l_n\left(1-P_N\right)\right\}\right]}{A+4B}$$

where

N = mean probable design life of structure in years;

P_{N} = risk level in N consecutive years (probability that the design wind speed is exceeded;

$X_{\mathrm{N,P}}$ = at least once in N successive years), nominal value = 0.63; and

$X_{50,0.63}$ = extreme wind speed for given values of N and P_{N}; .

A and *B* have the following values for different basic wind speed zones:

Zone m/s	***A**** m/s	***B**** m/s
33	23.1 (83.2)	2.6 (9.2)
39	23.3 (84.0)	3.9 (14.0)
44	24.4 (88.0)	5.0 (18.0)
47	24.4 (88.0)	5.7 (20.5)
50	24.7 (88.8)	6.3 (22.8)
55	25.2 (90.8)	7.6 (27.3)

* Values of *A* and *B* in ‘km/h’ are given within bracket

4.4.3.2.2 *Variation of wind speed with height in different terrains* (k_2)

Table 5 gives multiplying factors (k_2) by which the basic wind speed given in Fig. 1 shall be multiplied to obtain the wind speed at different heights, in each terrain category.

Table 5 Factors to Obtain Design Wind Speed Variation with Height in Different Terrains

(*Clause* 4.4.3.2.2)

xiv)	500	1.35	1.35	1.35	1.34

NOTE — For intermediate values of height *z* in a given terrain category, use linear interpolation.

4.4.3.2.3 *Terrain categories in relation to the direction of wind*

The terrain category used in the design of a structure may vary depending on the direction of wind under consideration. Where sufficient meteorological information is available, the basic wind speed may be varied for specific wind direction.

4.4.3.2.4 *Changes in terrain categories*

The velocity profile for a given terrain category does not develop to full height immediately with the commencement of that terrain category but develop gradually to height (h_x) which increases with the fetch or upwind distance (x).

a) *Fetch and developed height relationship* — The relation between the developed height (h_x) and the fetch (x) for wind-flow over each of the four terrain categories may be taken as given in Table 6; and

b) For structures of heights more than the developed height (h_x) in Table 6, the velocity profile may be determined in accordance with the following:

   1) The less or least rough terrain; or

   2) The method described in Annex E.

Table 6 Fetch and Developed Height Relationship

viii)	50	180	300	400	500

4.4.3.3 *Topography* (k_3 *factor*)

The basic wind speed V_b given in Fig. 1 takes into account the general level of site above sea level. This does not allow for local topographic features such as hills, valleys, cliffs, escarpments, or ridges which can significantly affect wind speed in their vicinity. The effect of topography is to accelerate wind near the summits of hills or crests of cliffs, escarpments or ridges and decelerate the wind in valleys or near the foot of cliffs, steep escarpments, or ridges.

The effect of topography shall be significant at a site when the upwind slope (θ) is more than about 3° and below that, the value of k_3 may be taken to be equal to 1.0. The value of k_3 is confined in the range of 1.0 to 1.36 for slopes more than 3°. A method of evaluating the value of k_3 for values more than 1.0 is given in Annex F. It may be noted that the value of k_3 varies with height above ground level, with a maximum near the ground and reducing to 1.0 at higher levels.

4.4.3.4 *Importance factor for cyclonic region* (k_4 *factor*)

The east coast of India is relatively more vulnerable for occurrences of severe cyclones. On the west coast, Gujarat is vulnerable for severe cyclones. Studies of wind speed and damage to buildings and structures point to the fact that the speeds given in the basic wind speed map are often exceeded during the cyclones. The effect of cyclonic storms is largely felt in a belt of approximately 60 km width at the coast. In order to ensure better safety of structures in this region (60 km wide on the east coast as well as on the Gujarat coast), the values of k_4 are stipulated as applicable according to the importance of the structure:

	k_4
Structures of post-cyclone importance for emergency services (such as cyclone shelters, hospitals, schools, communication towers, etc)	1.30
Industrial structures	1.15
All other structures	1.00

NOTE — For guidelines related to estimation of cyclonic factor (k4) as given in good practice [C-1(5)] may be referred.

4.4.4 *Hourly Mean Wind Speed*

The hourly mean wind speed at height z, for different terrains can be obtained as:

$$\overline{V}_{z,H} = \overline{k}_{2,i} V_b$$

where

$\overline{k}_{2,i}$ = hourly mean wind speed factor for terrain category 'i'.

$$= 0.1423\left[\ln\left(\frac{z}{z_{0,\mathrm{i}}}\right)\right]\left(z_{0,\mathrm{i}}\right)^{0.0706}$$

The design hourly mean wind speed at height z can be obtained as:

$$\overline{V}_{\mathrm{z,d}} = \overline{V}_{\mathrm{z,H}} k_1 k_3 k_4 \quad = V_{\mathrm{b}} k_1 \overline{k}_{2,\mathrm{i}} k_3 k_4$$

4.4.5 *Turbulence Intensity*

The turbulence intensity variations with height for different terrains can be obtained using the relations given below:

a) *Terrain category* 1

$$I_{\mathrm{z},1} = 0.3507 - 0.0535 \log_{10}\left(\frac{z}{z_{0,1}}\right)$$

b) *Terrain category* 2

$$I_{\mathrm{z},2} = I_{\mathrm{z},1} + \frac{1}{7}\left(I_{\mathrm{z},4} - I_{\mathrm{z},1}\right)$$

c) *Terrain category* 3

$$I_{\mathrm{z},3} = I_{\mathrm{z},1} + \frac{3}{7}\left(I_{\mathrm{z},4} - I_{\mathrm{z},1}\right)$$

d) *Terrain category* 4

$$I_{z,4} = 0.466 - 0.1358 \log_{10}\left(\frac{z}{z_{0,4}}\right)$$

4.4.6 *Off-shore Wind Velocity*

Cyclonic storms form far away from the sea coast and gradually reduce in speed as they approach the sea coast. Cyclonic storms generally extend up to about 60 km inland after striking the coast. Their effect on land is already reflected in basic wind speeds specified in Fig. 1. The influence of wind speed off the coast up to a distance of about 200 km may be taken as 1.15 times the value on the nearest coast in the absence of any definite wind data. The factor 1.15 shall be used in addition to k_4.

4.5 Wind Pressures and Forces on Buildings/Structures

4.5.1 *General*

The wind load on a building/structure shall be calculated for:

a) the building/structure as a whole;

b) individual structural elements as roofs and walls; and

c) individual cladding units including glazing and their fixings.

4.5.2 *Design Wind Pressure*

The wind pressure at any height above mean ground level shall be obtained by the following relationship between wind pressure and wind speed:

$$p_z = 0.6 V_{\mathrm{z}}^{2}$$

where

p_z = wind pressure at height z, in N/m^2; and

V_z = design wind speed at height z, in m/s.

The design wind pressure p_d can be obtained as:

$$p_d = K_d\,K_a\,K_c\,p_z$$

where

K_d = wind directionality factor;

K_a = area averaging factor; and

K_c = combination factor [*see* **4.5.3.3.13**].

The value of p_d, however shall not be taken as less than 0.70 p_z.

NOTES

1 The coefficient 0.6 (in SI units) in the above formula depends on a number of factors and mainly on the atmospheric pressure and air temperature. The value chosen corresponds to the average Indian atmospheric conditions.

2 K_d should be taken as 1.0 when considering local pressure coefficients.

4.5.2.1 *Wind directionality factor, K_d*

Considering the randomness in the directionality of wind and recognizing the fact that pressure or force coefficients are determined for specific wind directions, it is specified that for buildings, solid signs, open signs, lattice frameworks and trussed towers (triangular, square, rectangular) a factor of 0.90 may be used on the design wind pressure. For circular or near-circular forms this factor may be taken as 1.0.

For the cyclone affected regions also the factor K_d shall be taken as 1.0.

4.5.2.2 *Area averaging factor, K_a*

Pressure coefficients given in **4.5.3** are a result of averaging the measured pressure values over a given area. As the area becomes larger, the correlation of measured values decrease and *vice-versa*. The decrease in pressures due to larger areas may be taken into account as given in Table 7.

Table 7 Area Averaging Factor (K_a)

(*Clause* 4.5.2.2)

Sl No. (1)	**Tributary Area (A)** m^2 (2)	**Area Averaging Factor (K_a)**[1] (3)
i)	≤ 10	1.0
ii)	25	0.9
iii)	≥ 100	0.8

[1] Linear interpolation for intermediate values of tributary area, A is permitted.

4.5.2.2.1 *Tributary area*

a) *Overall structure* — For evaluating loads on frames the tributary area shall be taken as the centre to centre distances between frames multiplied by the individual panel dimension in the other direction together with overall pressure coefficients;

b) *Individual elements* — For beam type elements, purlins, etc, the tributary area shall be taken as effective span multiplied by spacing. The effective span is the actual span for mid span and cantilever load effects; and half the sum of adjacent spans for support moments and reactions;

c) For plate type elements, the area of individual plates between supports is taken as the tributary area; and

d) For glass cladding, individual pane area of glass is the tributary area.

4.5.3 *Pressure Coefficients*

The pressure coefficients are always given for a particular surface or part of the surface of a building/structure. The wind load acting normal to a surface is obtained by multiplying the area of that surface or its appropriate portion by the pressure coefficient (C_p) and the design wind pressure at the height of the surface from the ground. The average values of these pressure coefficients for some building shapes are given in **4.5.3.2** and **4.5.3.3**.

Average values of pressure coefficients are given for critical wind directions in one or more quadrants. In order to determine the maximum wind load on the building/structure, the total load should be calculated for each of the critical directions shown from all quadrants. Where considerable variation of pressure occurs over a surface, it has been sub-divided and mean pressure coefficients given for each of its several parts.

In addition, areas of high local suction (negative pressure concentration) frequently occurring near the edges of walls and roofs are separately shown. Coefficients for the local effects should only be used for calculation of forces on these local areas affecting roof sheeting, glass panels and individual cladding units including their fixtures. They should not be used for calculating force on entire structural elements such as roof, walls or structure as a whole.

NOTES

1 The pressure coefficients given in different tables have been obtained mainly from measurements on models in wind tunnels and the great majority of data available has been obtained in conditions of relatively smooth flow. Where sufficient field data exists as in the case of rectangular buildings, values have been obtained to allow for turbulent flow.

2 In recent years, wall glazing and cladding design has been a source of major concern. Although of less consequence than the collapse of main structures, damage to glass can be hazardous and cause considerable financial losses.

3 For pressure coefficients for structures not covered herein, reference may be made to specialist literature on the subject or advice may be sought from specialists in the subject.

4.5.3.1 *Wind load on individual members*

When calculating the wind load on individual structural elements such as roofs and walls and individual cladding units and their fittings, it is essential to take account of the pressure difference between opposite faces of such elements or units. For clad structures, it is, therefore, necessary to know the internal pressure as well as the external pressure. Then the wind load, F (in N), acting in a direction normal to the individual structural element or cladding unit is:

$$F = (C_{pe} - C_{pi})\,A\,p_d$$

where

C_{pe} = external pressure coefficient;

C_{pi} = internal pressure coefficient;

A = surface area of structural element or cladding unit, in m^2; and

p_d = design wind pressure, in N/m^2.

NOTES

1 If the surface design pressure varies with height, the surface areas of the structural element may be sub-divided so that the specified pressures are taken over appropriate areas.

2 Positive wind load indicates the force acting towards the structural element and negative away from it.

4.5.3.2 *Internal pressure coefficients*

Internal air pressure in a building depends upon the degree of permeability of cladding to the flow of air. The internal air pressure may be positive or negative depending on the direction of flow of air in relation to openings in the buildings.

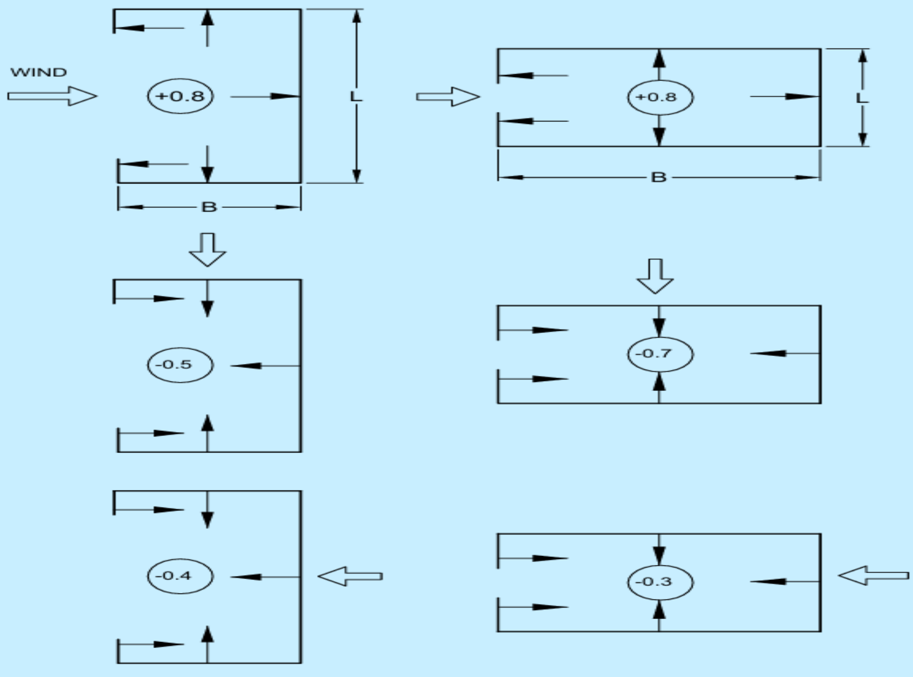
a) In the case of buildings where the claddings permit the flow of air with openings not more than about 5 percent of the wall area but where there are no large openings, it is necessary to consider the possibility of the internal pressure being positive or negative. Two design conditions shall be examined, one with an internal pressure coefficient of + 0.2 and another with an internal pressure coefficient of - 0.2.

   The internal pressure coefficient is algebraically added to the external pressure coefficient and the analysis which indicates greater distress of the member shall be adopted. In most situations a simple inspection of the sign of external pressure will at once indicate the proper sign of the internal pressure coefficient to be taken for design.

   NOTE — The term normal permeability relates to the flow of air commonly afforded by claddings not only through open windows and doors, but also through the slits round the closed windows and doors and through chimneys, ventilators and through the joints between roof coverings, the total open area being less than 5 percent of area of the walls having the openings.

b) *Buildings/structures with medium and large openings* — Buildings/structures with medium and large openings may also exhibit either positive or negative internal pressure depending upon the direction of wind. Buildings/structures with medium openings between about 5 percent to 20 percent of wall area shall be examined for an internal pressure coefficient of + 0.5 and later with an internal pressure coefficient of - 0.5 and the analysis which produces greater distress of the member shall be adopted. Buildings/structures with large openings, that is, openings larger than 20 percent of the wall area shall be examined once with an internal pressure coefficient of + 0.7 and again with an internal pressure coefficient of - 0.7 and the analysis which produces greater distress of the member shall be adopted.

Buildings/structures with one open side or opening exceeding 20 percent of wall area may be assumed to be subjected to internal positive pressure or suction similar to those of buildings with large openings. A few examples of buildings with one side openings are shown in Fig. 2 indicating values of internal pressure coefficients with respect to the direction of wind.



(a) FOR $\frac{B}{L} < 1$ (b) FOR $\frac{B}{L} > 1$

(c) FOR $\frac{B}{L} = 1$, USE AVERAGE VALUES
(ARROWS INDICATE DIRECTION OF WIND FLOW)

FIG. 2 VALUES OF INTERNAL PRESSURE COEFFICIENTS WITH RESPECT TO THE DIRECTION OF WIND FOR BUILDINGS WITH ONE SIDE OPENINGS

4.5.3.3 *External pressure coefficients*

4.5.3.3.1 *Walls*

The average external pressure coefficient for the walls of clad buildings of rectangular plan shall be as given in Table 8. In addition, local pressure concentration coefficients are also given.

4.5.3.3.2 *Pitched, hipped and monoslope roofs of clad buildings*

The average external pressure coefficients and pressure concentration coefficients for pitched roofs of rectangular clad building shall be as given in Table 9. Where no pressure concentration coefficients are given, the average coefficients shall apply. The pressure coefficients on the underside of any overhanging roof shall be taken in accordance with **4.5.3.3.5**.

NOTES

1 The pressure concentration shall be assumed to act outward (suction pressure) at the ridges, eaves, cornices and 90° corners of roofs.

2 The pressure concentration shall not be included with the net external pressure when computing overall loads.

3 For hipped roofs, pressure coefficients (including local values) may be taken on all the four slopes, as appropriate from Table 9 and be reduced by 20 percent for the hip slope.

For mono slope roofs of rectangular clad buildings, the average pressure coefficient and pressure concentration coefficient for mono slope (lean-to) roofs of rectangular clad buildings shall be as given in Table 10.

4.5.3.3.3 *Canopy roofs with* ($1/4 < h/w < 1$ *and* $1 < L/w < 3$)

The pressure coefficients are given in Table 11 and Table 12 separately for mono pitch and double pitch canopy roofs such as open-air parking garages, shelter areas, outdoor areas, railway platforms, stadiums and theatres. The coefficients take into account of the combined effect of the wind exerted on and under the roof for all wind directions; the resultant is to be taken normal to the canopy. Where the local coefficients overlap, the greater of the two given values should be taken. However, the effect of partial closures of one side and or both sides, such as those due to trains, buses and stored materials shall be foreseen and taken into account.

The solidity ratio, ϕ, is equal to the area of obstructions under the canopy divided by the gross area under the canopy, both areas normal to the wind direction. $\phi = 0$ represents a canopy with no obstructions underneath. $\phi = 1$ represents the canopy fully blocked with contents to the downwind eaves. Values of C_p for intermediate solidities may be linearly interpolated between these two extremes and apply upwind of the position of maximum blockage only. For downwind of the position of maximum blockage, the coefficients for $\phi = 0$ may be used.

In addition to the forces due to the pressures normal to the canopy, there will be horizontal loads on the canopy due to the wind pressure on any fascia and to friction over the surface of the canopy. For any wind direction, only the greater of these two forces need to be taken into account. Fascia loads should be calculated on the area of the surface facing the wind, using a force coefficient of 1.3. Frictional drag should be calculated using the coefficients given in **4.5.4.1**.

NOTE — Table 13 to Table 18 may be used to get internal and external pressure coefficients for pitches and troughed free roofs for some specific cases for which aspect ratios and roof slopes have been specified. However, while using Table 13 to Table 18 any significant departure from it should be investigated carefully. No increase shall be made for local effects except as indicated.

4.5.3.3.4 *Pitched and saw-tooth roofs of multi-span buildings*

For pitched and saw-tooth roofs of multi-span buildings, the external average pressure coefficients shall be as given in Table 19 and Table 20, respectively provided that all the spans shall be equal and the height to the eaves shall not exceed the span.

KEY PLAN

y = *h* or 0.15 *w*

Whichever is the lesser.

NOTE - 1 *h* is the height to eaves or parapet and *w* is the lesser horizontal dimension of a building.

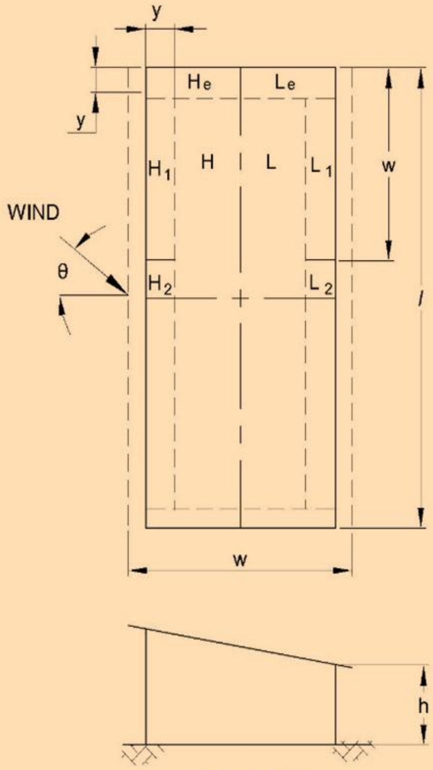
NOTE - 2 Where no local coefficients are given, the overall coefficient apply.

NOTE - 3 For hipped roofs the local coefficient for the hip ridge may be conservatively taken as the the appropriate ridge value.

NOTE - 4 *w* and *l* are dimensions between the walls excluding overhangs.

Table 10 External Pressure Coefficients (C_{pe}) for Monoslope Roofs for Rectangular Clad Buildings $\frac{h}{w}<2$

(*Clause* 4.5.3.3.2)



y = *h* or 0.15 *w*

Whichever is the lesser.

NOTE :- Area *H* and area *L* refer to the whole quadrant.

Each slope of a duopitch canopy should be able to withstand forces using both the maximum and the minimum coefficients, and the whole canopy should be able to support forces using one slope at the maximum coefficient with the other slope at the minimum coefficient. For duoptich canopies the centre of pressure should be taken to act at the centre of each slope.

Note :- W and L are overall width and length including overhangs

Frictional drag : When wing angle θ = 0°, horizontal forces due to frictional drag are allowed for in the above values, and

When wind angle θ = 90˚, allow for frictional drag in accordance with **4.5.4.1**

NOTE — Evidence on these buildings is fragmentary and any departure from the cases given should be investigated separately.

4.5.3.3.5 *Pressure coefficients on overhangs from roofs*

The pressure coefficients on the top overhanging portion of the roofs shall be taken to be the same as that of the nearest top portion of the non-overhanging portion of the roofs. The pressure coefficients for the underside surface of the overhanging portions shall be taken as follows and shall be taken as positive, if the overhanging portion is on the windward side:

a) 1.25, if the overhanging slopes downwards;

b) 1.00, if the overhanging is horizontal; and

c) 0.75, if the overhanging slopes upwards.

For overhanging portions on sides other than windward side, the average pressure coefficients on adjoining walls may be used.

4.5.3.3.6 *Curved roofs*

For curved roofs the external pressure coefficients shall be as given in Table 21. Allowance for local effects shall be made in accordance with Table 9. Two values of C_2 have been given for elevated curved roofs. Both the load cases have to be analysed and critical load effects are to be considered in design.

4.5.3.3.7 *Cylindrical structures*

For the purpose of calculating the wind pressure distribution around a cylindrical structure of circular cross section, the value of external pressure coefficients given in Table 22 may be used, provided that the Reynolds number is more than 10 000. They may be used for wind blowing normal to the axis of cylinders having axis normal to the ground plane and cylinders having their axis parallel to the ground plane. 'h' is height of a vertical cylinder or length of a horizontal cylinder. Where there is a free flow of air around both ends, h is to be taken as half the length when calculating h/D ratio.

In the calculation of resultant load on the periphery of the cylinder, the value of C_{pi} shall be taken into account. For open ended cylinders, C_{pi} shall be taken as follows:

a) - 0.8, where h/D is more than or equal to 0.3; and

b) - 0.5, where h/D is less than 0.3.

4.5.3.3.8 *Roofs and bottoms of cylindrical elevated structures*

The external pressure coefficients for roofs and bottoms of cylindrical elevated structures shall be as given in Table 23. Alternately, the pressure distribution given in Fig. 3 can be used together with the force coefficients given in Table 28 for the cylindrical portion.

4.5.3.3.9 *Combined roofs*

The average external pressure coefficients for combined roofs are shown in Table 24.

4.5.3.3.10 *Roofs with skylight*

The average external pressure coefficients for roofs with skylight are shown in Table 25.

4.5.3.3.11 *Grandstands*

The pressure coefficients on the roof (top and bottom) and rear wall of a typical grandstand roof which is open on three sides are given in Table 26. The pressure coefficients are valid for a particular ratio of dimensions as specified in Table 24 but may be used for deviations up to 20 percent. In general, the maximum wind load occurs when the wind is blowing into the open front of the stand, causing positive pressure under the roof and negative pressure on the roof.

4.5.3.3.12 *Spheres*

The external pressure coefficients for spheres shall be as given in Table 27.

4.5.3.3.13 *Frames*

When taking wind loads on frames of clad buildings it is reasonable to assume that the pressures or suctions inside and outside the structure shall not be fully correlated. Therefore, when taking the combined effect of wind loads on the frame, a reduction factor of $K_c = 0.90$ may be used over the building envelope when roof is subjected to pressure and internal pressure is suction, or *vice-versa*.

4.5.4 *Force Coefficients*

The value of force coefficients (C_f) apply to a building or structure as a whole and when multiplied by the effective frontal area (A_e) of the building or structure and design wind pressure, p_d gives the total wind load (F) on that particular building or structure, expressed as:

$$F = C_f A_e p_d$$

where

F = force acting in a direction specified in the respective tables; and

C_f = force coefficient for the building.

NOTES

1 The value of the force coefficient differs for the wind acting on different faces of a building or structure. In order to determine the critical load, the total wind load should be calculated for each wind direction.

2 If surface design pressure varies with height, the surface area of the building/structure may be sub-divided so that specified pressures are taken over appropriate areas.

3 In tapered buildings/structures, the force coefficients shall be applied after sub-dividing the building/structure into suitable number of strips and the load on each strip calculated individually, taking the area of each strip as A_e.

4 For force coefficients for structures not covered herein, reference may be made to specialist literature on the subject or advice may be sought from specialist in the subject.

4.5.4.1 *Frictional drag*

In certain buildings of special shape, a force due to frictional drag shall be taken into account in addition to those loads specified in **4.5.3**. For rectangular clad buildings, this addition is necessary only where the ratio d/h or d/b is more than 4. The frictional drag force, F', in the direction of the wind is given by the following formulae:

a) If $h \leq b$, $F' = C_f'(d - 4h)\, b\, p_d + C'_f(d - 4h)\, 2h\, p_d$; and

b) If $h > b$, $F' = C_f'(d - 4b)\, b\, p_d + C'_f(d - 4b)\, 2h\, p_d$.

The first term in each case gives the drag on the roof and the second on the walls. The C_f' has the following values:

a) 0.01 for smooth surfaces without corrugations or ribs across the wind direction;

b) 0.02 for surfaces with corrugations across the wind direction; and

c) 0.04 for surfaces with ribs across the wind direction.

For other buildings, the frictional drag has been indicated, where necessary, in the tables of pressure coefficients and force coefficients.

4.5.4.2 *Force coefficients for clad buildings*

4.5.4.2.1 *Clad buildings of uniform section*

The overall force coefficients for rectangular clad buildings of uniform section with flat roofs in uniform flow shall be as given in Fig. 4 and for other clad buildings of uniform section (without projections, except where otherwise shown) shall be as given in Table 28.

NOTE — Structures that are in the supercritical flow regime, because of their size and design wind velocity, may need further calculation to ensure that the greatest loads do not occur at some wind speed below the maximum, when the flow will be sub-critical.

The coefficients are for buildings without projections, except where otherwise shown.

In Table 28, $\overline{V}_d b$ is used as an indication of the airflow regime.

4.5.4.2.2 *Buildings of circular shapes*

Force coefficients for buildings of circular cross section shapes shall be as given in Table 28. However, more precise estimation of force coefficients for circular shapes of infinite length can be obtained from Fig. 5 taking into account the average height of surface roughness ε. When the length is finite the values obtained from Fig. 5 shall be reduced by the multiplication factor K (*See also* Table 31 and Annex G).

4.5.4.2.3 *Free standing walls and hoardings*

Force coefficients for free standing walls and hoardings shall be as given in Table 29.

To allow for oblique winds, the design shall also be checked for net pressure normal to the surface varying linearly from a maximum of 1.7 C_f at the windward edge to 0.44 C_f at the leeward edge.

The wind load on appurtenances and supports for hoardings shall be accounted for separately by using the appropriate net pressure coefficients. Allowance shall be made for shielding effects of one element on another.

	HEMISPHERICAL BOWL	0.4
	HEMISPHERICAL SOLID	1.2
	SPHERICAL SOLID	0.5 FOR $V_z D < 7$ 0.2 FOR $V_z D \geq 7$

4.5.4.2.4 *Solid circular shapes mounted on a surface*

The force coefficients for solid circular shapes mounted on a surface shall be as given in Table 30.

4.5.4.3 *Force coefficients for unclad buildings*

4.5.4.3.1 This section applies to permanently unclad buildings and to frameworks of buildings while temporarily unclad. In the case of buildings whose surfaces are well-rounded, such as those with elliptic, circular or oval cross sections, the total force can be more at a wind speed much less than maximum due to transition in the nature of boundary layer on them. Although this phenomenon is well known in the case of circular cylinders, the same phenomenon exists in the case of many other well-rounded structures and this possibility must be checked.

4.5.4.3.2 *Individual members*

a) The force coefficient given in Table 32 refers to members of infinite length. For members of finite length, the coefficients should be multiplied by a factor *K* that depends on the ratio *l*/*b* where *l* is the length of the member and *b* is the width across the direction of wind. Table 31 gives the required values of *K*. The following special cases must be noted while estimating *K*:

    1) when any member abuts on to a plate or wall in such a way that free flow of air around that end of the member is prevented, then the ratio of *l*/*b* shall be doubled for the purpose of determining *K*; and

    2) when both ends of a member are so obstructed, the ratio shall be taken as infinity for the purpose of determining *K*.

b) *Flat-sided members* — Force coefficients for wind normal to the longitudinal axis of flat-sided structural members shall be as given in Table 32.

The force coefficients are given for two mutually perpendicular directions relative to a reference axis on the structural member. They are denoted by C_{fn} and C_{ft} and give the forces normal and transverse, respectively to the reference plane as shown in Table 32.

Normal force $F_n = (C_{fn}\, p_d\, K)/b$

Transverse force $F_t = (C_{ft}\, p_d\, K)/b$

c) *Circular sections* — Force coefficients for members of circular section shall be as given in Table 28 (*See also* Annex G).

d) Force coefficients for wires and cables shall be as given in Table 33 according to the diameter (D), the design wind speed (V_d) and the surface roughness.

4.5.4.3.3 *Single frames*

Force coefficients for a single frame having either:

a) all flat sided members; or

b) all circular members in which all the members of the frame have either:

   1) $D\bar{V}_d$ less than 6 m^2/s; or

   2) $D\bar{V}_d$ more than or equal to 6 m^2/s. shall be as given in Table 31 according to the type of the member, the diameter (D), the design hourly mean wind speed ($\bar{V}_d$) and the solidity ratio (Φ). Force coefficients for a single frame not complying with the above requirements shall be calculated as follows:

$$C_f = \gamma\, C_{f\,\mathrm{super}} + (1-\gamma)\frac{A_{\mathrm{circ\,sub}}}{A_{\mathrm{sub}}} C_{f\,\mathrm{sub}} + (1-\gamma)\frac{A_{\mathrm{flat}}}{A_{\mathrm{sub}}} C_{f\,\mathrm{flat}}$$

where

$C_{f\,\mathrm{super}}$ = force coefficient for the supercritical circular members as given in Table 34 or Annex G;

γ = $\frac{\text{Area of the frame in a supercritical flow}}{A_e}$;

A_e = effective frontal area;

$A_{\mathrm{circ\,sub}}$ = effective area of subcritical circular members;

$C_{f\,\mathrm{sub}}$ = force coefficient for subcritical circular members as given in Table 34 or Annex G;

$C_{f\,\mathrm{flat}}$ = force coefficient for the flat sided members as given in Table 34;

A_{flat} = effective area of flat-sided members; and

A_{sub} = $A\mathrm{circ\ sub} + A\mathrm{flat}$.

4.5.4.3.4 *Multiple frame buildings*

This Section applies to structures having two or more parallel frames where the windward frames may have a shielding effect upon the frames to leeward side. The windward frame and any unshielded parts of other frames shall be calculated in accordance with **4.5.4.3.3**, but the wind load on the parts of frames that are sheltered should be multiplied by a shielding factor which is dependent upon the solidity ratio of the windward frame, the types of members comprising the frame and the spacing ratio of the frames. The values of the shielding factors are given in Table 35.

Where there are more than two frames of similar geometry and spacing, the wind load on the third and subsequent frames should be taken as equal to that on the second frame. The loads on the various frames shall be added to obtain total load on the structure.

a) The frame spacing ratio is equal to the centre to centre distance between the frames, beams or girders divided by the least overall dimension of the frames, beam or girder measured in a direction normal to the direction of wind. For triangular framed structures or rectangular framed structures diagonal to the wind, the spacing ratio should be calculated from the mean distance between the frames in the direction of the wind.

b) Effective solidity ratio, Φ_e:

$\Phi_e = \Phi$ for flat-sided members.

Φ_e is to be obtained from Fig. 6 for members of circular cross sections.

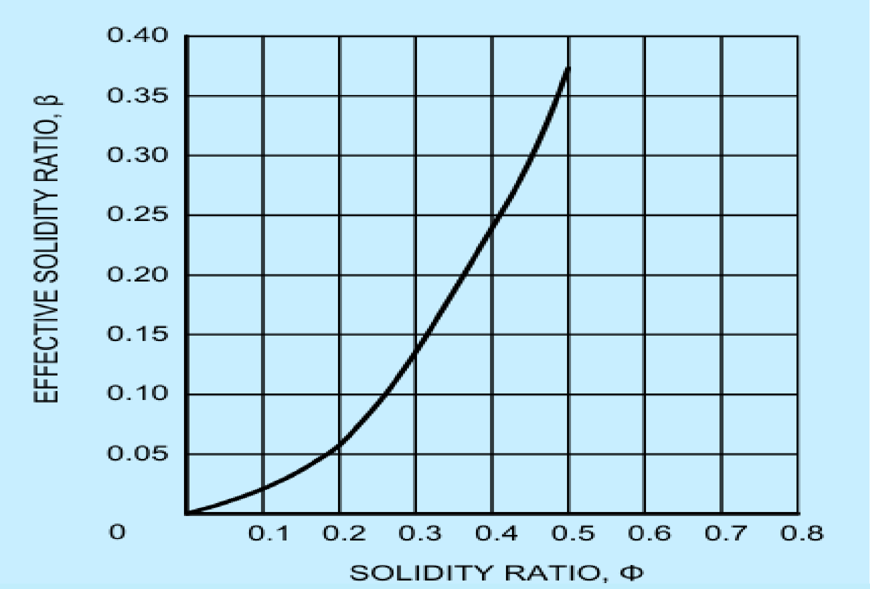

FIG. 6 EFFECTIVE SOLIDITY RATIO FOR CIRCULAR SECTION MEMBERS

4.5.4.3.5 *Lattice towers*

a) Force coefficient for lattice towers of square or equilateral triangle section with flat sided members for wind blowing against any face shall be as given in Table 36;

b) For square lattice towers with flat-sided members the maximum load, which occurs when the wind blows into a corner, shall be taken as 1.2 times the load for the wind blowing against a face;

c) For equilateral triangle lattice towers with flat-sided members, the load may be assumed to be constant for any inclination of wind to a face;

d) Force coefficients for lattice towers of square section with circular members, all in the same flow regime, may be as given in Table 37; and

e) Force coefficients for lattice towers of equilateral-triangle section with circular members all in the same flow regime may be as given in Table 38.

4.5.4.3.6 *Tower appurtenances*

The wind loading on tower appurtenances, such as ladders, conduits, lights, elevators, etc shall be calculated using appropriate net pressure coefficients for these elements. Allowance may be made for shielding effect from other elements.

4.6 Interference Effects

4.6.1 *General*

Wind interference is caused by modification in the wind characteristics produced by the obstruction caused by an object or a building/structure in the path of the wind. If such wind strikes another structure, the wind pressures usually get enhanced, though there can also be some shielding effect between two very closely spaced buildings/structures. The actual phenomenon is too complex to justify generalization of the wind forces/pressures produced due to interference which can only be ascertained by detailed wind tunnel/CFD studies. However, some guidance can be provided for the purpose of preliminary design. To account for the effect of interference, a wind interference factor (IF) has been introduced as a multiplying factor to be applied to the design wind pressure/force. Interference effects can be more significant for tall buildings. The interference factor is defined as the ratio between the enhanced pressure/force in the grouped configuration to the corresponding pressure/force in isolated configuration. Since the values of IF can vary considerably based on building geometry and location, the given values of IF are a kind of median values and are meant only for preliminary design estimates. The designer is advised that for assigning values of IF for final design particularly for tall buildings, specialist literature be consulted or a wind tunnel study carried out.

4.6.2 *Roof of Low Rise Buildings*

Maximum increase in wind force on the roof due to interference from similar buildings in case of closely spaced low rise buildings with flat roofs may be up to 25 percent for c/c distance (x) between the buildings of 5 times the dimension (b) of the interfering building normal to the direction of wind (*see* Fig. 7). Interference effect beyond 20b may be considered to be negligible. For intermediate spacing linear interpolation may be used.

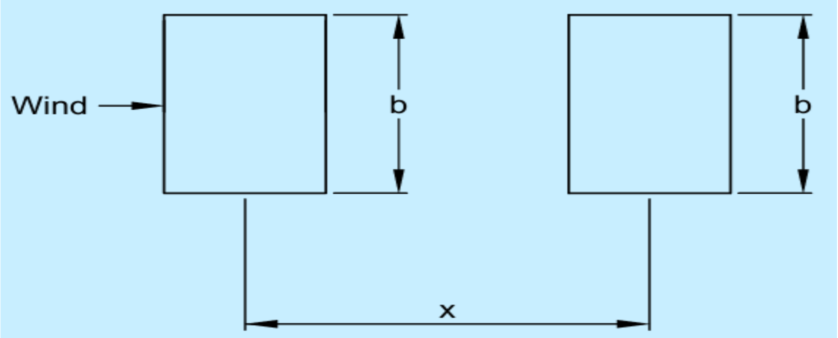

FIG. 7 LOW-RISE BUILDING IN TANDEM CAUSING INTERFERENCE EFFECT

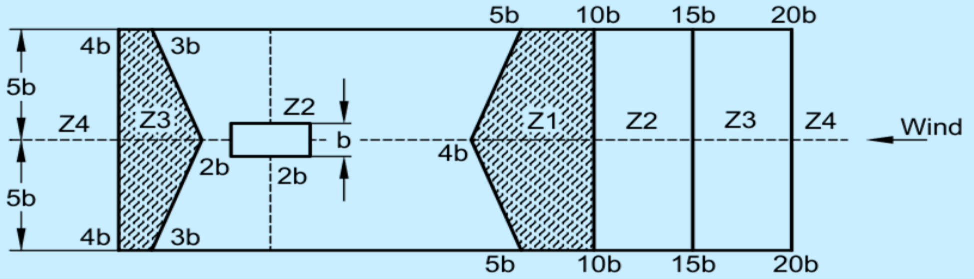
4.6.3 *Tall Buildings*

Based on studies on tall rectangular buildings, Fig. 8 gives various zones of interference. The interference factor (IF), which needs to be considered as a multiplication factor for wind loads corresponding to isolated building, may be assumed as follows for preliminary estimate of the wind loads under interference caused by another interfering tall building of same or more height located at different zone Z1 to zone Z4 as shown in Fig. 8:

Zone	Z1	Z2	Z3	Z4
IF	1.35	1.25	1.15	1.07

The interference effect due to buildings of height less than one-third of the height of the building under consideration may be considered to be negligible while for interference from a building of intermediate height, linear interpolation may be used between one-third and full height.



Z1 Zone of high interference
Z2 Zone of moderate interference
Z3 Zone of low interference
Z4 Zone of insignificant interference

FIG. 8 INTERFERENCE ZONES FOR TALL RECTANGULAR BUILDINGS OF SAME OR GREATER HEIGHT

4.7 Dynamic Effects

4.7.1 *General*

Flexible slender structures and structural elements shall be investigated to ascertain the importance of wind induced oscillations or excitations in along wind and across wind directions.

In general, the following guidelines may be used for examining the problems of wind-induced oscillations:

a) Buildings and closed structures with a height to minimum lateral dimension ratio of more than about 5.0, or

b) Buildings and structures whose natural frequency in the first mode is less than 1.0 Hz.

Any building or structure which satisfies either of the above two criteria shall be examined for dynamic effects of wind.

NOTES

1 The fundamental time period (T), in second, may either be established by experimental observations on similar buildings or calculated by any rational method of analysis. In the absence of such data, T may be determined as follows for multi-storied buildings:

a) For moment resistant frames without bracings or shear walls resisting the lateral loads:

$$T = 0.1\,n$$

where

n = number of storeys, including basement storeys.

b) For all others:

$$T = \frac{0.09H}{\sqrt{d}}$$

where

H = total height of the main structures of the building, in m; and

d = maximum base dimension of building in metres in a direction parallel to the applied wind force.

2 If preliminary studies indicate that wind-induced oscillations are likely to be significant, investigations should be pursued with the aid of analytical methods or if necessary, by means of wind tunnel tests on models.

3 Across-wind motions may be due to lateral gustiness of the wind, unsteady wake flow (for example, vortex shedding), negative aerodynamic damping or due to a combination of these effects. These cross-wind motions may become critical in the design of tall buildings/structures.

4 Motions in the direction of wind (also known as buffeting) are caused by fluctuating wind force associated with gust. The excitation depends on gust energy available at the resonant frequency.

5 The eddies shed from an upstream body may intensify motion in the direction of the wind and may also affect cross-wind motion.

6 The designer should also be aware of the following three forms of wind-induced motion which are characterized by increasing amplitude of oscillation with the increase of wind speed.

a) *Galloping* — Galloping is transverse oscillations of some structures due to the development of aerodynamic forces which are in phase with the motion. It is characterized by the progressively increasing amplitude of transverse vibration with increase of wind speed. The cross sections which are particularly prone to this type of excitation include the following:

1) All structures with non-circular cross sections, such as triangular, square, polygons, as well as angles, crosses and T sections.
2) Twisted cables and cables with ice encrustations.

b) *Flutter* — Flutter is unstable oscillatory motion of a structure due to coupling between aerodynamic force and elastic deformation of the structure. Perhaps the most common form is oscillatory motion due to combined bending and torsion. Although oscillatory motion in each degree of freedom may be damped, instability can set in due to energy transfer from one mode of oscillation to another and the structure is seen to execute sustained or divergent oscillations with a type of motion which is a combination of the individual modes of vibration. Such energy transfer takes place when the natural frequencies of modes taken individually are close to each other (ratio being typically less than 2.0). Flutter can set in at wind speeds much less than those required for exciting the individual modes of motion. Long span suspension bridge decks or any member of a structure with large values of d/t (where d is the length of the member and t is its dimension parallel to wind stream) are prone to low speed flutter. Wind tunnel testing is required to determine critical flutter speeds and the likely structural response. Other types of flutter are single degree of freedom stall flutter, torsional flutter, etc.

c) *Ovalling* — Thin walled structures with open ends at one or both ends such as oil storage tanks and natural draught cooling towers in which the ratio of the diameter or minimum lateral dimension to the wall thickness is of the order of 100 or more are prone to ovalling oscillations. These oscillations are characterized by periodic radial deformation of the hollow structure.

7 Buildings and structures that may be subjected to significant wind excited oscillations require careful investigations. It is to be noted that wind induced oscillations may occur at wind speeds lower than the design wind speed.

8 Analytical methods for the evaluation of response of dynamic structures to wind loading can be found in the special publications.

9 In assessing wind loads due to such dynamic phenomenon as galloping, flutter and ovalling, in the absence of the required information either in the special publications or other literature, expert advice should be sought including experiments on models in boundary layer wind tunnels.

4.7.2 *Motion due to Vortex Shedding*

4.7.2.1 *Slender structures*

For a structure, the vortex shedding frequency, fs, shall be determined by the following formula:

$$fs = \frac{S_t \overline{V}_{z,H}}{b}$$

where

S_t = strouhal number

$\overline{V}_{z,H}$ = hourly mean wind speed at height z; and

b = breadth of a structure or structural member normal to the wind direction in the horizontal plane.

a) *Circular structures* — For structures of circular cross section:

S_t = 0.20 for $D\overline{V}_{z,H}$ less than 6 m^2/s; and

= 0.25 for $D\overline{V}_{z,H}$ more than or equal to 6 m^2/s.

b) *Rectangular structures* — For structures of rectangular cross section:

$$S_t = 0.10$$

NOTES

1 Significant cross wind motions may be produced by vortex shedding, if the natural frequency of the structure or structural element is equal to the frequency of the vortex shedding within the range of expected wind speeds. In such cases, further analysis should be carried out on the basis of special publications.

2 Unlined welded steel cylindrical structures are prone to excitations by vortex shedding.

3 Intensification of the effects of periodic vortex shedding has been reported in cases where two or more similar structures are located in close proximity, for example at less than $20b$ apart, where b is the dimension of the structure normal to the wind.

4 The formulae given in 4.7.2.1(a) is valid for infinitely long cylindrical structures. The value of S_t decreases slowly as the ratio of length to maximum transverse width decreases, the reduction being up to about half the value, if the structure is only three times higher than its width. Vortex shedding need not be considered, if the ratio of length to maximum transverse dimension is less than 2.0.

4.8 Dynamic Wind Response

4.8.1 *General*

Tall buildings/structures which are 'wind sensitive' shall be designed for dynamic wind loads. Hourly mean wind speed is used as a reference wind speed to be used in dynamic wind analysis. For calculation of along wind loads and response (bending moments, shear forces, or tip deflections) the Gust factor (GF) method is used as specified in 4.8.2. The across wind design peak base overturning moment and tip deflection shall be calculated using 4.8.3.

4.8.2 *Along Wind Response*

For calculation of along-wind load effects at a level s on a building/structure, the design hourly mean wind pressure at height z shall be multiplied by the Gust factor (G). This factor is dependent on both the overall height h and the level s under consideration (*see* Fig. 9). For calculation of base bending moment and deflection at the top of the building/structure, 's' should be taken as zero.

Note that $0 < s <$ h and $s < z < h$.

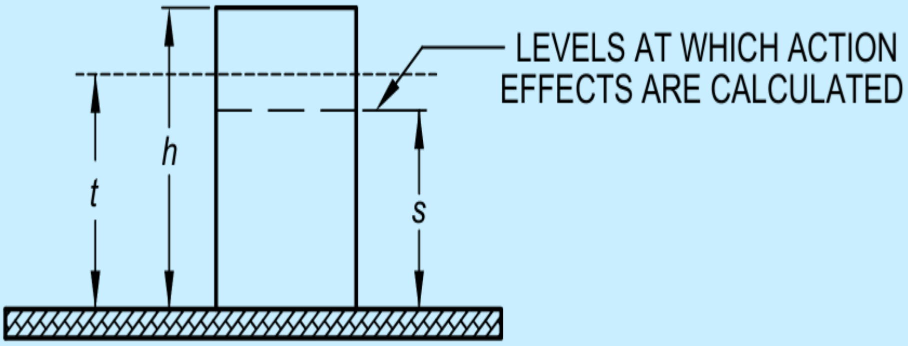


FIG. 9 NOTATIONS FOR HEIGHTS

The design peak along wind base bending moment (M_a) shall be obtained by summing the moments resulting from design peak along wind loads acting at different heights, z, along the height of the building/structure and can be obtained from:

$$M_a = \sum F_z \, z$$

$$F_z = C_{f,z} A_z \bar{p}_d G$$

where

F_z = design peak along wind load on the building/structure at any height z;

A_z = the effective frontal area of the building/structure at any height z, in m^2;

$\bar{p}_d$ = design hourly mean wind pressure corresponding to $\bar{V}_{z,d}$ and obtained as $0.6\bar{V}_{z,d}^2$ (N/m^2);

$\bar{V}_{z,d}$ = design hourly mean wind speed at height z, in m/s (*see* **4.4.4**);

$C_{f,z}$ = the drag force coefficient of the building/structure corresponding to the area A_z;

G = Gust Factor and is given by:

$$1 + r\sqrt{\left[g_v^2 B_s (1+\phi)^2 + \frac{H_s g_R^2 SE}{\beta}\right]}$$

r = roughness factor which is twice the longitudinal turbulence intensity, $I_{h,i}$ (*see* **4.4.5**);

g_v = peak factor for upwind velocity fluctuation

= 3.0 for category 1 and 2 terrains; and

= 4.0 for category 3 and 4 terrains;

B_s = background factor indicating the measure of slowly varying component of fluctuating wind load cused by the lower frequency wind speed variations

$$= \frac{1}{\left[1 + \frac{\sqrt{0.26(h-s)^2 + 0.46 b_{sh}^2}}{L_h}\right]}$$

where

b_{sh} = average breadth of the building/structure between heights s and h;

L_h = measure of effective turbulence length scale at the height, h, in m;

$= 85\left(\frac{h}{10}\right)^{0.25}$ for terrain category 1 to 3; and

$= 70\left(\frac{h}{10}\right)^{0.25}$ for terrain category 4

ϕ = factor to account for the second order turbulence intensity;

$$= \frac{g_v I_{h,i}\sqrt{B_s}}{2}$$

$I_{h,i}$ = turbulence intensity at height h in terrain category i;

H_s = height factor for resonance response;

$$= 1 + \left(\frac{s}{h}\right)^2$$

S = size reduction factor given by

$$= \frac{1}{\left[1 + \frac{3.5 f_a h}{\overline{V}_{h,d}}\right]\left[1 + \frac{4 f_a b_{0h}}{\overline{V}_{h,d}}\right]}$$

where

b_{0h} = average breadth of the building/structure between 0 and h;

E = spectrum of turbulence in the approaching wind stream:

$$\frac{\pi N}{\left(1 + 70.8 N^2\right)^{5/6}}$$

where

N = an effective reduced frequency

$$= \frac{f_a L_h}{\overline{V}_{h,d}}$$

f_a = first mode natural frequency of the building/structure in along wind direction, in Hz

$\overline{V}_{h,d}$ = design hourly mean wind speed at height, h in m/s (*see* **4.4.4**);

β = damping coefficient of the building/structure (*see* Table 39); and

g_R = peak factor for resonant response.

$$= \sqrt{\left[2\ln(3600 f_a)\right]}$$

Table 39 Suggested Values of Structural Damping Coefficients

(*Clauses* 4.8.2 *and* 4.8.3.1)

Sl No. (1)	Kind of Structure (2)	Damping Coefficient, β (3)
i)	Welded steel structures	0.010
ii)	Bolted steel structures/RCC structures	0.020
iii)	Prestressed concrete structures	0.016

4.8.2.1 *Peak acceleration in along wind direction*

The peak acceleration at the top of the building/structure in along wind direction ($\hat{\ddot{x}}$ in m/s^2) is given by the following equation:

$$\hat{\ddot{x}} = (2\pi f_a)^2 \bar{x}\, g_R\, r \sqrt{\frac{SE}{\beta}}$$

where

$\bar{x}$ = mean deflection at the position where the acceleration is required. Other notations are same as given in 9.2. For computing the peak acceleration in the along wind direction, a mean wind speed at the height of the building/structure, $\bar{V}_h$ corresponding to a 5 year mean return period shall be used. A reduced value of 0.011 is also suggested for the structural damping, β for reinforced concrete structures.

4.8.3 *Across Wind Response*

This section gives method for determining equivalent static wind load and base overturning moment in the across wind direction for tall enclosed buildings and towers of rectangular cross section. Calculation of across wind response is not required for lattice towers.

The across wind design peak base bending moment M_c for enclosed buildings and towers shall be determined as follows:

$$M_c = 0.5 g_h \bar{p}_h b h^2 (1.06 - 0.06k)\sqrt{\frac{\pi C_{fs}}{\beta}}$$

where

g_h = a peak factor;

= $\sqrt{[2\ln(3600 f_c)]}$ in cross wind direction;

$\bar{p}_h$ = hourly mean wind pressure at height h, in Pa;

b = breadth of the structure normal to the wind, in m;

h = height of the structure, in m;

k = a mode shape power exponent for representation of the fundamental mode shape as represented by:

$$\psi(z) = \left(\frac{z}{h}\right)^k \text{; and}$$

f_c = first mode natural frequency of the building/structure in across wind direction, in Hz.

The across wind load distribution on the building/structure can be obtained from M_c using linear distribution of loads as given below:

$$F_{z,c} = \left(\frac{3M_c}{h^2}\right)\left(\frac{z}{h}\right)$$

where

$F_{z,c}$ = across wind load per unit height at height z.

4.8.3.1 *Peak acceleration in across wind direction*

The peak acceleration at the top of the building/structure in across-wind direction ($\hat{\ddot{y}}$ in m/s^2) with approximately constant mass per unit height shall be determined as follows:

$$\hat{\ddot{y}} = 1.5 \frac{g_h \, \bar{p}_h \, b}{m_0}\left(0.76 + 0.24k\right)\sqrt{\left(\frac{\pi C_{fs}}{\beta}\right)}$$

where

C_{fs} = across wind force spectrum coefficient generalized for a linear mode, (*see* Fig. 10);

β = damping coefficient of the building/structure (*see* Table 39); and

m_0 = the average mass per unit height of the structure, in kg/m.

Typical values of the mode shape power exponent, k are as follows:

a) uniform cantilever, $k = 1.5$

b) slender framed structure (moment resisting), $k = 0.5$

c) building with a central core and moment resisting façade, $k = 1.0$

d) lattice tower decreasing in stiffness with height, or a tower with a large mass at the top, $k = 2.3$

4.8.4 *Combination of Along Wind and Across Wind Load Effects*

The along wind and across wind loads have to be applied simultaneously on the building/structure during design.

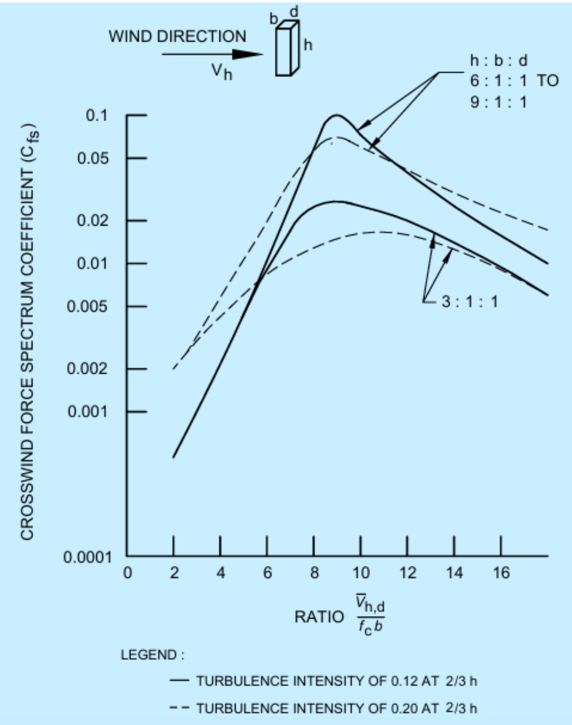

FIG. 10(A) VALUES OF THE CROSS WIND FORCE SPECTRUM COEFFICIENT FOR SQUARE SECTION BUILDINGS

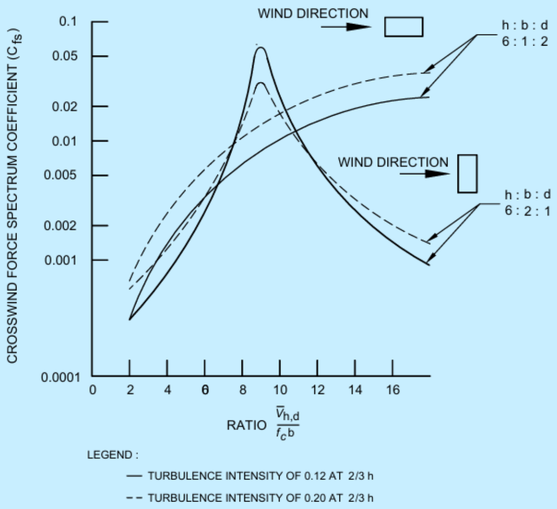

FIG. 10(B) VALUES OF THE CROSS WIND FORCE SPECTRUM COEFFICIENT FOR 2 : 1 AND 1 : 2 RECTANGULAR SECTION BUILDINGS

FIG. 10 WIND FORCE SPECTRUM COEFFICIENTS

5 EARTHQUAKE EFFECTS — GENERAL

For assessment of earthquake loads, determination of seismic zones and earthquake resistant design of buildings, good practice [C-1(6)] shall be referred to. Additionally, it outlines the principles of earthquake-resistant design, desirable and unacceptable features of earthquake-resistant structural system configurations and methods of analysis and treatment of geotechnical aspects for all types of structures.

6 EARTHQUAKE EFFECTS — BUILDINGS

6.1 *Masonry Buildings*

6.1.1 Provisions given in Part C ‘Structural Design/Section 4 Masonry’ of this NBCS deals with the selection of materials, special aspects related to design and construction of new earthquake-resistant masonry buildings, including masonry buildings using rectangular masonry units with cast in-situ or prefabricated flooring and roofing elements.

6.1.2 Guidelines for earthquake-resistant design of buildings constructed using masonry of low strength and earthen buildings are covered in as per good practice [C-1(7)].

6.2 *Concrete Buildings*

Provisions given in Part C ‘Structural Design/ Section 5 Structural Concrete’ of this NBCS and good practice [C-1(8)] deal with the selection of materials and special aspects related to design and construction for cast in-situ earthquake-resistant reinforced concrete (RC) buildings.

6.3 *Steel Buildings*

Provisions given in Part C ‘Structural Design/Sec 6A Steel’ of this NBCS and good practice [C-1(9)] deal with the selection of materials, special aspects related to design and construction for earthquake-resistant steel buildings.

7 SNOW LOAD

7.1 This clause deals with snow loads on roofs of buildings. Roofs should be designed for the actual load due to snow or for the imposed loads specified in 3, whichever is more severe.

NOTE — Mountainous regions in northern and eastern parts of India are subjected to snow-fall. In northern India, parts of union territory of Jammu and Kashmir (J and K), union territory of Ladakh, Himachal Pradesh, Uttarakhand and in eastern India, parts of Arunachal and Sikkim experience snow-fall of varying depths two to three times in a year.

7.2 Notations

a) μ (Dimensionless) — Nominal values of the shape coefficients, taking into account snow drifts, sliding snow, etc, with subscripts, if necessary;

b) l_i (m) — Horizontal dimension with numerical subscripts, if necessary;

c) h_i (m) — Vertical dimensions with numerical subscripts, if necessary;

d) β_i (degree) — Roof and other surface slope;

e) s_0 (kPa) — Characteristic value of snow load on the ground with a specified annual exceedance probability;

f) s (kPa) — Snow load on roofs other surfaces; and

g) A (m) — Site altitude above sea level.

7.3 Snow Load in Roof(s)

7.3.1 The minimum design snow load on a roof area or any other area above ground which is subjected to snow accumulation is obtained by multiplying the snow load on ground, s_o by the shape coefficient μ, as applicable to the particular roof area considered, expressed as:

$$s = \mu\, s_o$$

where

s = design snow load on plan area of roof, in Pa;

μ = shape coefficient (*see* 7.4); and

s_o = ground snow load in Pa (1 Pa=1 N/m^2).

NOTE — Ground snow load at any place depends on the critical combination of the maximum depth of undisturbed aggregate cumulative snow fall and its average density. In due course the characteristic snow load on ground for different regions will be included based on studies. Till such time the users of this NBCS are advised to contact either Defence Geoinformatics Research Establishment (DGRE), Chandigarh of Defence Research and Development Organization (DRDO), or India Meteorological Department (IMD), Pune in the absence of any specific information for any location.

7.3.2 *Characteristic Ground Snow Load* (s_0)

The characteristic ground snow load (s_0) at any site is defined based on an annual probability of exceedance of 0.034 and corresponds to a mean return period of 30 years. The value of s_0 (kPa) for any site in snow-bound regions of Indian Himalayas should be obtained using the procedure described in Annex H.

NOTE — Annex H gives the characteristic ground snow load map for union territory of Jammu and Kashmir, union territory of Ladakh, Himachal Pradesh, Uttarakhand and Sikkim resulting from studies conducted by DGRE, Chandigarh.

7.3.3 *Partial Loading Due to Melting, Sliding, Snow Redistribution and Snow Removal*

A loading corresponding to severe imbalances resulting from snow removal, redistribution, sliding, melting, etc (for example, zero snow load on specific parts of the roof) should always be considered. Such considerations are particularly important for structures which are sensitive to unbalance loading (for example, curved roofs, arches, domes, collar beam roofs, continuous beam systems). Water load due to ponding in flat roof as well as valley of pitched roof shall be taken as not less than 0.24 kPa.

7.3.4 *Ponding Instability*

7.3.4.1 Roofs shall be designed to preclude ponding.

7.3.4.2 For flat roofs (or with a small slope), roof deflections caused by snow loads shall be investigated when determining the likelihood of ponding from rain-on-snow or from snow meltwater. The angle for snow melting is 15º.

7.4 Shape Coefficients

7.4.1 *General Principles*

In perfectly calm weather, falling snow would cover roofs and the ground with a uniform blanket of snow and the design snow load could be considered as a uniformly distributed load. Truly uniform loading conditions, however, are rare and have usually only been observed in areas that are sheltered on all sides by high trees, buildings, etc. In such a case, the shape coefficient would be equal to unity.

In most regions, snow-falls are accompanied or followed by winds. The winds will redistribute the snow and on some roofs especially multilevel roofs, the accumulated drift load may reach a multiple of the ground load. Roofs which are sheltered by other buildings, vegetation, etc, may collect more snow load than the ground level. The phenomenon is of the same nature as that illustrated for multilevel roofs in 7.4.2.4.

So far, sufficient data are not available to determine the shape coefficient on a statistical basis. Therefore, a nominal value is given. A representative sample of roofs is shown in 7.4.2. However, in special cases such as strip loading, cleaning of the roof periodically by deliberate heating of the roof, etc, have to be treated separately. However, no reduction in load of snow on roof having underside insulation and/or internal heating system shall be done.

The distribution of snow in the direction parallel to the caves is assumed to be uniform.

7.4.2 *Shape Coefficients for Selected Types of Roofs*

7.4.2.1 *Monopitched and simple pitched roofs*

	 Simple Flat and Monopitch Roofs	 Simple Pitched Roofs (Positive Roof Slope)*
$0° < \beta \leq 15°$		$\mu_2 = \mu_1 = 0.80$

$15° < \beta \leq 30°$	$\mu_1 = 0.80$	$\mu_2 = 0.80 + 0.40\left(\frac{\beta - 15}{15}\right)$ $\mu_1 = 0.80$
$30° < \beta \leq 60°$	$\mu_1 = 0.80\left(\frac{60 - \beta}{30}\right)$	$\mu_2 = 1.20\left(\frac{60 - \beta}{30}\right)$ $\mu_1 = 0.80\left(\frac{60 - \beta}{30}\right)$
$\beta > 60°$	$\mu_1 = 0$	$\mu_2 = \mu_1 = 0$
*For asymmetrical simple pitched roofs, each side of the roof shall be treated as one half of corresponding symmetrical roofs.		

NOTES

1 For monopitch roof, wind direction will not affect the value of μ.

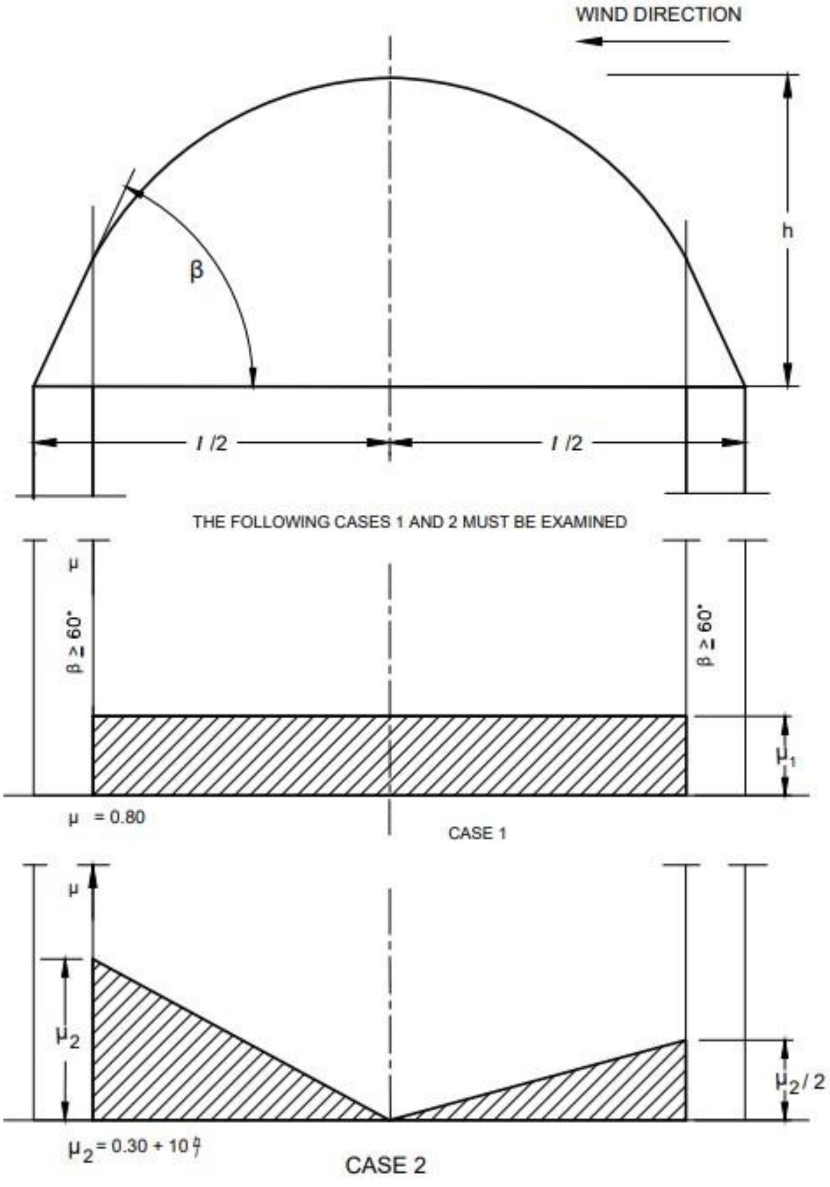
2 The values of $\mu 1$ and $\mu 2$ shall be reversed in case the wind direction changes from left to right for simple pitched roof.

7.4.2.2 *Multiple pitched roofs*

	 Simple on Multiple Pitched Roofs (Negative Roof Slope)	 Two – Span or Multispan Roofs
$0° < \beta \leq 30°$	$\mu_2 = 0.80\left(\frac{30 + \beta}{30}\right)$ $\mu_1 = 0.80$	$\mu_2 = 0.80\left(\frac{30 + \beta}{30}\right)$ $\mu_1 = 0.80$
$30° < \beta \leq 60°$	$\mu_1 = 1.60$ $\mu_1 = 0.80\left(\frac{60 - \beta}{30}\right)$	$\mu_2 = 1.60$ $\mu_1 = 0.80\left(\frac{60 - \beta}{30}\right)$

$\beta > 60°$	$\mu_1 = 1.60$ $\mu_1 = 0$	$\mu_2 = 1.60$ $\mu_1 = 0$

7.4.2.3 *Simple curved roofs*



WIND DIRECTION
h
β

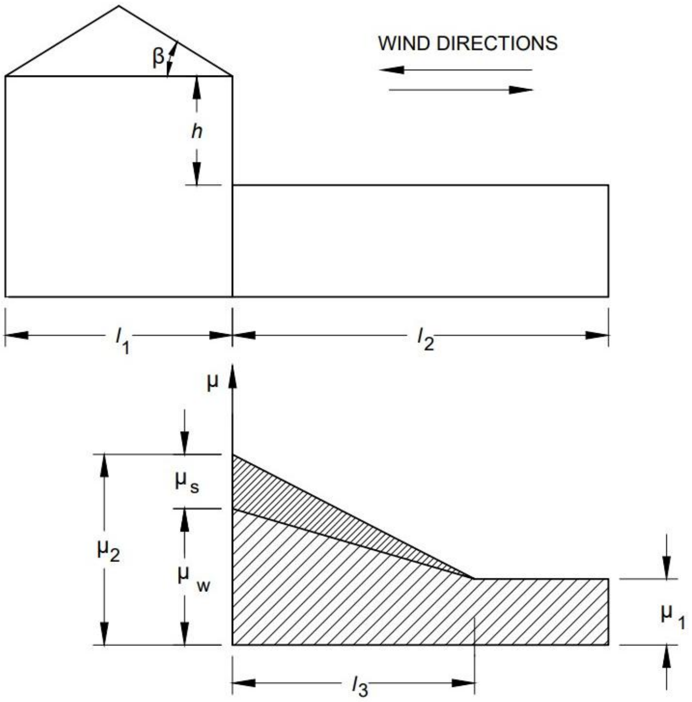
μ2
μ2 / 2
μ2 = 0.30 + 10 h/l
CASE 2

Restrictions:

$\mu_2 \leq 2.3$

$\mu = 0 \; if \; \beta \geq 60^o$

7.4.2.4 *Multilevel roofs*[1)]



$$\mu_1 = 0.80$$

$$\mu_2 = \mu_s + \mu_w$$

where

μ_s = due to sliding; and

μ_w = due to wind.

$l_3 = 2h$ [2)] but is restricted as follows:

$$5\ m \leq l_3 \leq 15\ m$$

$$\mu_w = \frac{l_1 + l_2}{2h} \leq \frac{kh}{s_0} \text{ with the restriction } 0.80 \leq \mu_w \leq 4.0$$

where

h is in metres

s_0 is in kPa (kN/m^2)

$k = 2\ \text{kN/m}^2$

NOTES

1 A more extensive formula for μ_w is described in Annex J.

2 If $l_2 < l_3$, the coefficient μ is determined by interpolation between μ_1 and μ_2.

If $\beta > 15^\circ$: μ_s is determined from an additional load amounting to 50 percent of the maximum total load on the adjacent slope of the upper roof and is distributed linearly as shown in the figure. The load on the upper roof is calculated according to **7.4.2.1** or **7.4.2.2**.

If $\beta \leq 15^\circ$: $\mu_s = 0$

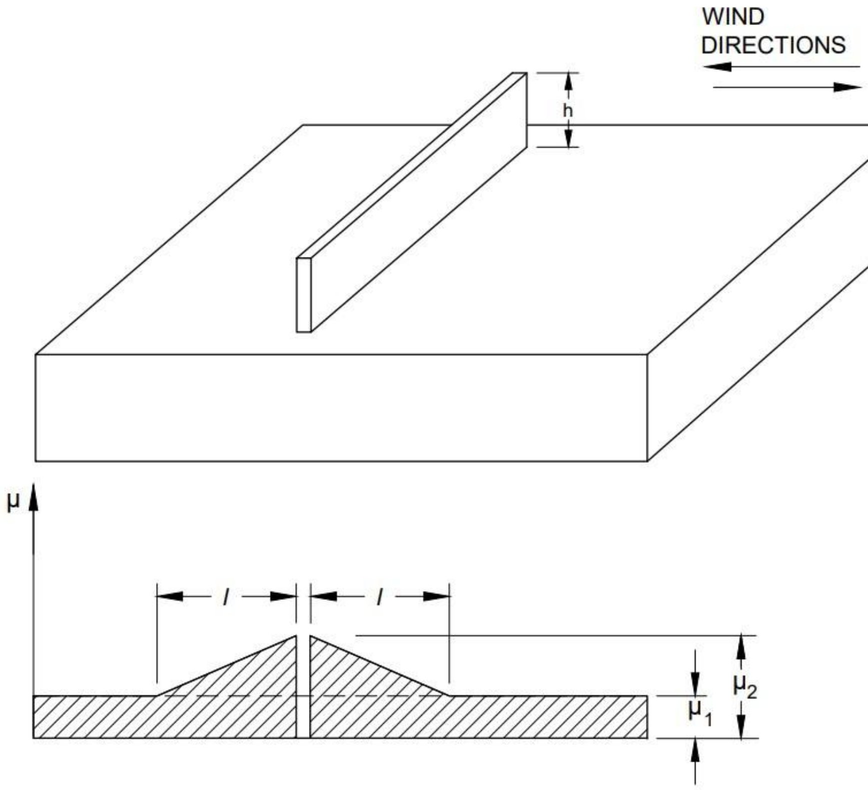
$5\,m \leq l_3 \leq 15\,m$

μ_2 and $\mu_3 = \mu_s + \mu_w$, are calculated according to **7.4.2.1**, **7.4.2.2** and **7.4.2.4**

7.4.2.6 *Roofs with local projections and obstructions*



$$\mu_2 = \frac{kh}{s_0}$$

$$\mu_1 = 0.80$$

where

h is in metres

s_0 is in kPa $(\mathrm{kN/m^2})$

$k = 2\,\mathrm{kN/m^2}$

$l = 2\,h$

Restriction:

$0.80 \le \mu_2 \le 2.0$

$5\,m \le l \le 15\,m$

7.4.3 *Shape Coefficients in Areas Exposed to Wind*

The shape coefficients given in 7.4.2 and Annex J may be reduced by 15 percent, provided the designer has demonstrated that the following conditions are fulfilled:

a) The building is located in an exposed location such as open level terrain with only scattered buildings, trees or other obstructions so that the roof is exposed to the winds on all sides and is not likely to become shielded in the future by obstructions higher than the roof within a distance from the building equal to ten times the height of the obstruction above the roof level; and

b) The roof does not have any significant projections such as parapet walls which may prevent snow from being blown off the roof.

NOTE — In some areas, winter climate may not be of such a nature as to produce a significant reduction of roof loads from the snow load on the ground. This typically occurs in winter calm valleys in mountainous regions, where layers of snow may accumulate on roofs without any appreciable removal by wind, as well as in relatively higher temperature areas where the maximum snow load may result from a single snowstorm, occasionally without significant wind removal. In such conditions, the determination of shape coefficients should be based on local experience, with due consideration given to the likelihood of wind drifting and sliding.

8 SPECIAL LOADS

8.1 This clause gives guidance on loads and load effects due to temperature changes, soil and hydrostatic pressures, internally generating stresses (due to creep, shrinkage, differential settlement, etc), accidental loads, etc, to be considered in the design of buildings as appropriate. This clause also includes guidance on load combinations. The nature of loads to be considered for a particular situation is to be based on engineering judgment (*See also* **3.6**)

8.2 Temperature Effects

8.2.1 Expansion and contraction due to changes in temperature of the materials of a structure shall be considered in design. Provision shall be made either to relieve the stress by the provision of expansion/contraction joints in accordance with good practice [C-1(10)] or design the structure to carry additional stresses due to temperature effects as appropriate to the problem.

8.2.1.1 The temperature range varies for different regions and under different diurnal and seasonal conditions. The absolute maximum and minimum temperature which may be expected in different localities in the country are indicated in good practice [C-1(11)]. These figures may be used for guidance in assessing the maximum variations of temperature.

8.2.1.2 The temperatures indicated are the air temperatures in the shade. The range of variation in temperature of the building materials may be appreciably greater or less than the variation of air temperature and is influenced by the condition of exposure and the rate at which the materials composing the structure absorb or radiate heat. This difference in temperature variations of the material and air should be given due consideration.

8.2.1.3 The structural analysis must take account of changes of the mean (through the section) temperature in relation to the initial (st) and the temperature gradient through the section:

a) it should be borne in mind that the changes of mean temperature in relation to the initial are liable to differ as between one structural element and another in buildings or structures, as for example, between the external walls and the internal elements of a building. The distribution of temperature through section of single-leaf structural elements may be assumed linear for the purpose of analysis; and

b) the effect of mean temperature changes t_1 and t_2 and the temperature gradients v_1 and v_2 in the hot and cold seasons for single-leaf structural elements shall be evaluated on the basis of analytical principles.

NOTES

1 For portions of the structure below ground level, the variation of temperature is generally insignificant. However, during the period of construction, when the portions of the structure are exposed to weather elements, adequate provision should be made to encounter adverse effects, if any.

2 If it can be shown by engineering principles, or if it is known from experience, that neglect of some or all the effects of temperature do not affect the structural safety and serviceability, they need not be considered in design.

8.3 Hydrostatic and Soil Pressure

8.3.1 In the design of structures or parts of structures below ground level such as retaining walls and other walls in basement floors, the pressure exerted by the soil or water or both shall be duly accounted for on the basis of established theories. Due allowance shall be made for possible surcharge from stationary or moving loads. When a portion or whole of the soil is below the free water surface, the lateral earth pressure shall be evaluated for weight of soil diminished by buoyancy and the full hydrostatic pressure.

8.3.1.1 All foundation slabs and other footings subjected to water pressure shall be designed to resist a uniformly distributed uplift equal to the full hydrostatic pressure. Checking of overturning of foundation under submerged condition shall be done considering buoyant weight of foundation.

8.3.2 While determining the lateral soil pressure on column like structural members such as pillars which rest in sloping soils, the width of the member shall be taken as follows (*see* Fig. 11).

Sl No. (1)	*Actual Width of Member* (2)	*Ratio of Effective Width to Actual Width* (3)
i)	Less than 0.5 m	3.0
ii)	Beyond 0.5 m and up to 1 m	3.0 to 2.0
iii)	Beyond 1 m	2.0

The relieving pressure of soil in front of the structural member concerned may generally not be taken into account.

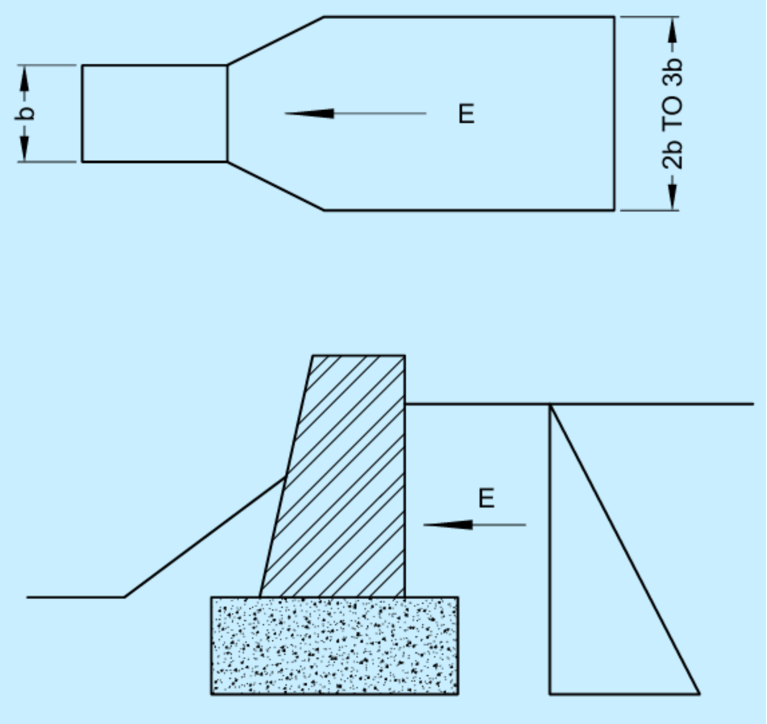


FIG. 11 SKETCH SHOWING EFFECTIVE WIDTH OF PILLAR FOR CALCULATING SOIL PRESSURE

8.3.3 Safe-guarding of structures and structural members against overturning and horizontal sliding shall be verified. Imposed loads having favourable effect shall be disregarded for the purpose. Due consideration shall be given to the possibility of soil being permanently or temporarily removed.

8.4 Fatigue

8.4.1 *General*

Fatigue cracks are usually initiated at points of high stress concentration. These stress concentrations may be caused by or associated with holes (such as bolt or rivet holes in steel structures), welds including stray or fusions in steel structures, defects in materials and local and general changes in geometry of members. The cracks usually propagate if the loading is cyclic and repetitive.

Where there is such cyclic and repetitive loading, sudden changes of shape of a member or part of a member, especially in regions of tensile stress and/or local secondary bending, shall be avoided. Suitable steps shall be taken to avoid critical vibrations due to wind and other causes.

8.4.2 Where necessary, permissible stresses shall be reduced to allow for the effects of fatigue. Allowance for fatigue shall be made for combinations of stresses due to dead load and imposed load. Stresses due to wind and earthquakes may be ignored, when fatigue is being considered, unless otherwise specified in relevant Codes of practice.

Each element of the structure shall be designed for the number of stress cycles of each magnitude to which it is estimated that the element is liable to be subjected during the expected life of the structure. The number of cycles of each magnitude shall be estimated in the light of available date regarding the probable frequency of occurrence of each type of loading.

NOTE — Apart from the general observations made herein, the section is unable to provide any precise guidance in estimating the probabilistic behaviour and response of structures of various types arising out of repetitive loading approaching fatigue conditions in structural members, joints, materials, etc.

8.5 Structural Safety During Construction

All loads required to be carried by the structures or any part of it due to storage or positioning of construction materials and erection equipment including all loads due to operation of such equipment, shall be considered as erection loads. Proper provision shall be made, including temporary bracings, to take care of all stresses due to erection loads. The conjunction with the temporary bracings shall be capable of sustaining these erection loads, without exceeding the permissible stresses specified in respective Codes of practice. Dead load, wind load and such parts of imposed load, as would be imposed on the structure during the period of erection, shall be taken as acting together with erection loads.

8.6 Accidental Loads

The occurrence of which, with a significant value, is unlikely on a given structure over the period of time under consideration and also in most cases, is of short duration. The occurrence of an accidental load could, in many cases, be expected to cause severe consequences, unless special measures are taken.

The accidental loads arising out of human action include the following:

a) Impacts and collisions;
b) Explosions; and
c) Fire.

Characteristic of the above stated loads are that they are not a consequence of normal use and that they are undesired and that extensive effects are made to avoid them. As a result, the probability of occurrence of an accidental load is small whereas the consequences may be severe.

The causes of accidental loads may be:

a) inadequate safety of equipment (due to poor design or poor maintenance); and
b) wrong operation (due to insufficient teaching or training, indisposition, negligence or unfavourable external circumstances).

In most cases, accidental loads only develop under a combination of several unfavourable occurrences. In practical applications, it may be necessary to neglect the most unlikely loads. The probability of occurrence of accidental loads, which are neglected, may differ for different consequences of a possible failure. A data base for a detailed calculation of the probability will seldom be available.

8.6.1 *Impact and Collisions*

8.6.1.1 *General*

During an impact, the kinetic impact energy has to be absorbed by the vehicle hitting the structure and by the structure itself. In an accurate analysis, the probability of occurrence of an impact with a certain energy object hitting the structure and the structure itself at the actual place must be considered. Impact energies for dropped object should be based on the actual loading capacity and lifting height.

Common sources of impact are:

a) vehicles;

b) dropped objects from cranes, fork lifts, etc;

c) cranes out of control, crane failures; and

d) flying fragments.

The codal requirements regarding impact from vehicles and cranes are given in **8.6.1.2** and **8.6.1.3**.

8.6.1.2 The requirements for loads as a result of collision between vehicle and structural or non-structural elements shall be as per **8.6.1.2.1** and **8.6.1.2.2**.

8.6.1.2.1 *Collisions between vehicles and structural elements*

In road traffic, the requirement that a structure shall be able to resist collision may be assumed to be fulfilled, if it is demonstrated that the structural element is able to stop a fictitious vehicle, as described below. It is assumed that the vehicle strikes the structural element at a height of 1.2 m in any possible direction and at a speed of 10 m/s (36 km/h).

The fictitious vehicle shall be considered to consist of two masses m_1 and m_2 which during compression of the vehicle, produce an impact force increasing uniformly from zero, corresponding to the rigidities C_1 and C_2. It is assumed that the mass m_1 is broken completely before the breaking of mass m_2 begins.

The following numerical values should be used:

a) $m_1 = 400$ kg, $C_1 = 10\ 000$ kN/m, the vehicle is compressed; and

b) $m_2 = 12\ 000$ kg, $C_2 = 300$ kN/m, the vehicle is compressed.

NOTE — The described fictitious collision corresponds in the case of a non-elastic structural element to a maximum static force of 630 kN for the mass m_1 and 600 kN for the mass m_2 irrespective of the elasticity, it will therefore be on the safe side to assume the static force to be 630 kN.

In addition, breaking of the mass m_1 will result in an impact wave, the effect of which will depend, to a great extent, on the kind of structural element concerned. Consequently, it will not always be sufficient to design for the static force.

8.6.1.2.1.1 *For structural elements in stilts and car parking levels*

For structural elements in stilts and car parking levels, where driveways and car parking are provided in the buildings which have limited vehicle speeds, the design shall take care of the following considerations:

a) Speed of the vehicle to be 20 km/h maximum (since within a building and inside the car parks, speed of the vehicle may not generally be more than 20 km/h); and

b) Impact to be considered at a height of 450 mm to 600 mm.

Structural elements such as columns, RC walls or vertical load resisting elements shall be designed for loads due to the above unless protected by separate resisting system.

8.6.1.2.2 *Collision between vehicles and non-structural elements:*

Non-structural elements, such as vehicle barriers for car parks shall be designed to resist the impact and the momentum as outlined below:

a) The horizontal force F (in kN), normal to and uniformly distributed over any length of 1.5 m of a barrier for a car park, required to withstand the impact of a vehicle shall be as given below:

$$F = \frac{0.5mv^2}{\delta_c + \delta_b}$$

where

m = gross mass of the vehicle, in kg;

v = velocity of the vehicle normal to the barrier, in m/s;

δ_c = deformation of the vehicle, in mm; and

δ_b = deflection of the barrier, in mm.

b) Where the car park has been designed on the basis that the gross mass of the vehicles using it will not exceed 2500 kg, the following values shall be used to determine the force F:

m = 1500 kg;
v = 4.5 m/s;
δ_c = 100 mm;

For a rigid barrier, for which δ_b may be taken as zero, the force, F, appropriate to vehicles up to 2500 kg gross mass, shall be taken as 150 kN.

c) Where the car park has been designed for vehicles whose gross mass exceeds 2500 kg, the following values shall be used to determine the force F:

m = actual mass of the vehicle for which the car park is designed, in kg;

v = 4.5 m/s;

δ_c = 100 mm;

d) The force determined as in (b) or (c) may be considered to act at bumper height. In the case of car parks intended for motor cars whose gross mass does not exceed 2500 kg, this height may be taken as 375 mm above the floor level.

e) Barriers to access ramps of car parks have to withstand one-half of the force determined in (b) or (c) acting at a height of 610 mm above the ramp.

Opposite to the ends of straight ramps intended for downward travel, which exceed 20 m in length, the barrier shall be designed to withstand twice the force determined in (b) or (c) acting at a height of 610 mm above the ramp.

NOTE – The mass of 1500 kg is taken as being more representative of the vehicle population than the extreme value of 2500 kg.

8.6.1.3 *Safety railings*

With regard to safety, railings put up to protect structures against collision due to road traffic, it should be shown that the railings are able to resist the impact as described in 8.6.1.2.

NOTE — When a vehicle collides with safety railings, the kinetic energy of the vehicle will be absorbed partly by the deformation of the railings and partly by the deformation of the vehicle. The part of the kinetic energy which the railings should be able to absorb without breaking down may be determined on the basis of the assumed rigidity of the vehicle during compression.

8.6.1.4 *Crane impact load on buffer stop*

The basic horizontal load P_y (tonne), acting along the crane track produced by impact of the crane on the buffer stop, is calculated by the following formula:

$$P_y = MV^2/F$$

where

V = speed at which the crane is traveling at the moment of impact (assumed equal to half the nominal value) (m/s).

F = maximum shortening of the buffer, assumed equal to 0.1 m for light duty, mediuL-duty and heavy-duty cranes with flexible load suspension and loading capacity not exceeding 50 t and 0.2 m in every other cranes.

M = reduced crane mass, (t.s^2/m); and is obtained by the formula:

$$M = \frac{1}{g}\left[\frac{P_h}{2} + \left(P_t + kQ\right)\frac{L_k - l}{L_k}\right]$$

where

P_h = crane bridge weight (*t*);

P_t = crab bridge weight (*t*);

k = coefficient, assumed equal to zero for cranes with flexible load suspension and to one for cranes with rigid suspension;

Q = crane loading capacity (*t*);

L_k = crane span (m); and

ℓ = nearness of crab (m); and

g = acceleration due to gravity (9.81 m/s^2).

8.6.2 *Explosions*

8.6.2.1 *General*

Explosions may cause impulsive loading on a structure. The following types of explosions are particularly relevant:

a) Internal gas explosions which may be caused by leakage of gas piping (including piping outside the room), evaporation from volatile liquids or unintentional evaporation from surface material (for example, fire);

b) Internal dust explosions;

c) Boiler failure;

d) External gas cloud explosions; and

e) External explosions of high explosives (TNT, dynamite).

The codal requirement regarding internal gas explosions is given in 8.6.2.2.

8.6.2.2 *Explosion effect in closed rooms*

Gas explosion may be caused, for example by leaks in gas pipes (inclusive of pipes outside for room), evaporation from volatile liquids or unintentional evaporation of gas from wall sheathings (for example, caused by fire).

NOTES

1 The effect of explosions depends on the exploding medium, the concentration of the explosion, the shape of the room, possibilities of ventilation of the explosion and the ductility and dynamic properties of the structure. In rooms with little possibility for relief of the pressure from the explosion, very large pressures may occur.

2 Internal over pressure from an internal gas explosion in rooms of sizes comparable to residential rooms and with ventilation areas consisting of window glass breaking at a pressure of 4 kN/m^2 (3 mm to 4 mm machine made glass) may be calculated from the following method:

a) The over pressure is assumed to depend on a factor A/V, where A is the total windows area, in m^2 and V is the volume, in m^3, of the room considered;

b) The internal pressure is assumed to act simultaneously upon all walls and floors in one closed room; and

c) The action q_o may be taken as static action.

3 If account is taken of the time curve of the action, the schematic correspondence between pressure and time is assumed (*see* Fig. 12), where t_1 is the time from the start of combustion until maximum pressure is reached and t_2 is the time from maximum pressure to the end of combustion. For t_1 and t_2, the most unfavourable values should be chosen in relation to the dynamic properties of the structures. However, the values should be chosen within the intervals as given in Fig. 13.

Figure 12 is based on tests with gas explosions in room corresponding to ordinary residential flats and should, therefore, not be applied to considerably different conditions. The figure corresponds to an explosion caused by town gas and it might, therefore, be somewhat on the safe side in rooms where there is only the possibility of gases with a lower rate of combustion.

The pressure may be applied solely in one room or in more rooms at the same time. In the latter case, all rooms are incorporated in the volume V. Only windows or other similarly weak and light weight structural elements may be taken to be ventilation areas even though certain limited structural parts break at pressures less than q_o.

Figure 12 is given purely as guide and probability of occurrence of an explosion should be checked in each case using appropriate values.

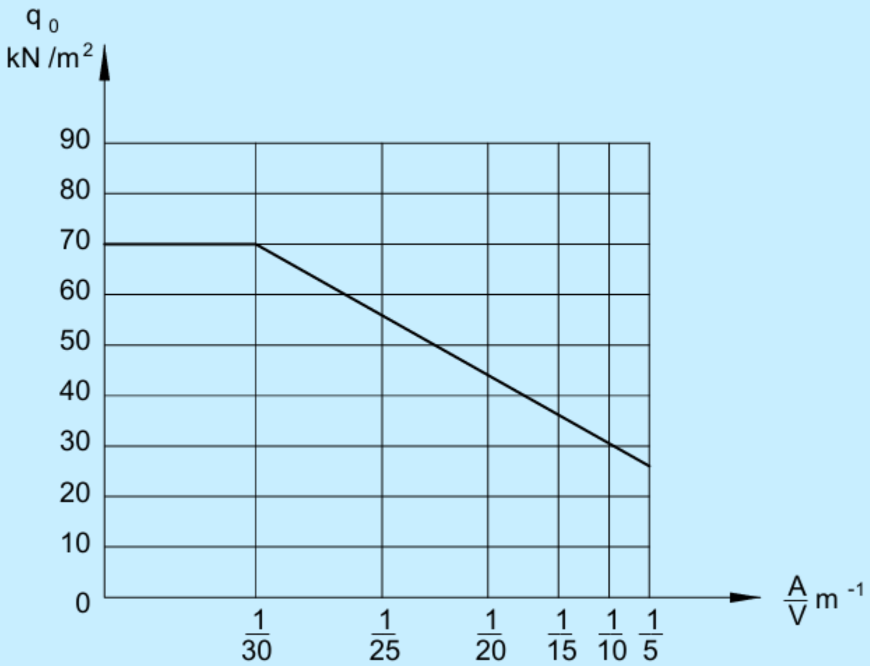

FIG. 12 SKETCH SHOWING RELATION BETWEEN PRESSURE AND TIME

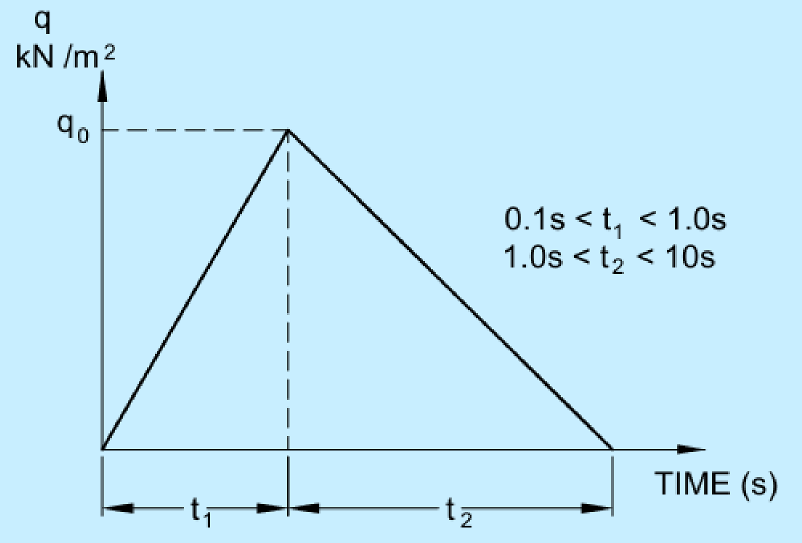

FIG. 13 SKETCH SHOWING TIME INTERVAL AND PRESSURE

8.6.3 *Vertical Load on Air Raid Shelters*

8.6.3.1 *Characteristic values*

As regards buildings in which the individual floors are acted upon by a total characteristic imposed action of up to 5.0 kN/m^2, vertical actions on air raid shelters generally located below ground level, for example, basement, etc, should be considered to have the following characteristic values:

a) Buildings with up to 2 storeys : 28 kN/m^2

b) Buildings with 3-4 storeys : 34 kN/m^2

c) Buildings with more than 4 storeys : 41 kN/m^2

d) Buildings of particularly stable construction irrespective of the number of storeys : 28 kN/m^2

In the case of buildings with floors that are acted upon by a characteristic imposed action larger than 5.0 kN/m^2, the above values should be increased by the difference between the average imposed action on all storeys above the one concerned and 5.0 kN/m^2.

NOTES

1 By storeys it is understood, every utilizable storey above the shelter.

2 By buildings of a particular stable construction, it is understood, buildings in which the load- bearing structures are made from reinforced *in-situ* concrete.

8.6.4 *Fire*

8.6.4.1 *General*

Possible extraordinary loads during a fire may be considered as accidental actions. Examples are loads from people along escape routes and loads on another structure from structure failing because of a fire.

8.6.4.2 *Thermal effects during fire*

The thermal effect during fire may be determined from one of the following methods:

a) Time-temperature curve and the required fire resistance (in min); and

b) An energy balance method.

If the thermal effect during fire is determined from an energy balance method, the fire load is taken to be:

$$q = 12\ t_b$$

where

q = fire action (KJ/m^2 floor); and

t_b = required fire resistance (in min) {*see* [C-1(12)]}.

NOTE — The fire action is defined as the total quantity of heat produced by complete combustion of all combustible material in the fire compartment, inclusive of stored goods and equipment together with building structures and building materials.

8.7 Vibrations

For general details on loads due to vibrations, reference may be made to Annex K.

8.8 Blast Loads

For provisions related to blast loads, *see* Annex L.

8.9 Other Loads

Other loads not included in this Section, such as special loads due to technical process, moisture and shrinkage effects, etc, should be taken into account where stipulated by building design codes or established in accordance with the performance requirement of the structure.

8.10 Landslide Control Measures

Mountainous and hilly terrains are prone to slope instability arising from geological, hydrological and seismic factors, further aggravated by unplanned developmental activities. The following good practices address the specific aspects towards hazard assessment, design and construction:

Sl No. (1)	*Aspects* (2)	*Accepted Standard*(*s*) (3)
i)	Guidelines for preparation of landslide hazard zonation maps	[C-1(13)]
ii)	Preparation of landslide risk assessment maps, combining hazard probability with potential damage through a risk assessment matrix	[C-1(13)]
iii)	Site-specific investigation and stability analysis, including geological mapping, subsurface exploration, laboratory testing and numerical modelling	[C-1(13)]
iv)	Landslide control measures with emphasis on drainage management, slope modification, reinforcement, bio-engineering and protective works	[C-1(13)]
v)	Design and construction of different types of retaining walls	[C-1(13)]
vi)	Micropiles for slope stabilization	[C-1(13)]
vii)	Surface water management in hilly areas	[C-1(13)]
viii)	Siting, design and selection of materials for residential buildings in hilly areas	[C-1(13)]

8.11 Cyclone Resistant Buildings

Cyclone-prone regions are vulnerable to high wind speeds, wind-borne debris and storm surges, which can cause extensive damage to buildings, particularly low-rise and kutcha houses. The following good practices address aspects of loads, design, construction and assessment for improving resilience:

Sl No.	*Aspect*	*Accepted Standard*
(1)	(2)	(3)
i)	Guidelines for improving the cyclonic resistance of low-rise houses and other buildings	[C-1(14)]
ii)	Guidelines for survey of housing and building typology in cyclone prone areas for assessment of vulnerability of regions and post-cyclone damage estimation	[C-1(14)]
iii)	Guidelines for design and construction of cyclone shelters	[C-1(14)]
iv)	Method for determination of performance relating to safety of external building envelope impacted by wind-borne debris	[C-1(14)]
v)	Guidelines for improving the cyclonic resistance capacity of kutcha houses	[C-1(14)]

9 LOAD COMBINATIONS

9.1 General

A judicious combination of the loads keeping in view the probability of:

a) their acting together; and

b) their disposition in relation to other loads and severity of stresses or deformations caused by the combinations of the various loads is necessary to ensure the required safety and economy in the design of a structure.

9.2 Load Combinations

Keeping the aspect specified in **9.1**, the various loads should, therefore, be combined in accordance with the stipulation in the relevant design Codes. In the absence of such recommendations, the following loading combinations, whichever combination produces the most unfavourable effect in the building, foundation or structural member concerned may be adopted (as a general guidance). It should also be recognized in load combinations that the simultaneous occurrence of maximum values of wind, earthquake, imposed and snow loads is not likely.

a) *DL*;

b) *DL* and *IL*;

c) *DL* and W*L*;

d) *DL* and E*L*;

e) *DL* and T*L*;

f) *DL*, *IL* and *WL*;

g) *DL*, *IL* and *EL*;

h) *DL*, *IL* and *TL*

j) *DL*, W*L* and *TL*;

k) *DL*, *EL* and *TL*;

m) *DL*, *IL*, *WL* and *TL*; and

n) *DL*, *IL*, *EL* and *TL*

(*DL* = dead load, *IL* = imposed load, *WL* = wind load, *EL* = earthquake load and *TL* = temperature load).

NOTES

1 When snow load is present on roofs, replace imposed load by snow load for the purpose of above load combinations.

2 The relevant design codes shall be followed for permissible stresses when the structure is designed by working stress method and for partial safety factors when the structure is designed by limit state design method for each of the above load combinations.

3 Whenever imposed load (*IL*) is combined with earthquake load (*EL*), the appropriate part of imposed load as specified in **5** should be used, both for evaluating earthquake effect and also for combined load effects used in such combination.

4 For the purpose of stability of the structure as a whole against overturning, the restoring moment shall be not less than 1.2 times the maximum overturning moment due to dead load plus 1.4 times the maximum overturning moment due to imposed loads. In cases where dead load provides the restoring moment, only 0.9 times the dead load shall be considered. The restoring moments due to imposed loads shall be ignored. In case of high water table, the effects of buoyancy have to be suitably taken into consideration.

5 In case of high water able, the factor of safety of 1.2 against uplift alone shall be provided.

6 The structure shall have a factor against sliding of not less than 1.4 under the most adverse combination of the applied loads/forces. In this case, only 0.9 times the dead load shall be taken into account.

7 Where the bearing pressure on soil due to wind alone is less than 25 percent of that due to dead load and imposed load, it may be neglected in design where this exceeds 25 percent, foundation may be so proportioned that the pressure due to combined effect of dead load, imposed load and wind load does not exceed the allowable bearing pressure by more than 25 percent. When earthquake effect is included, the permissible increase in allowable bearing pressure in the soil shall be in accordance with 5.

8 Reduced imposed load specified in 3 for the design of supporting structures should not be applied in combination with earthquake forces.

9 Other loads and accidental load combination not included should be dealt with appropriately.

10 Crane load combinations are covered in **3.6.4**.

10 MULTI-HAZARD RISK IN VARIOUS DISTRICTS OF INDIA

10.1 Multi-hazard Risk Concept

The commonly encountered hazards are:

a) Earthquake;

b) Cyclone;

c) Wind storm;

d) Floods;

e) Landslides;

f) Liquefaction of soils;

g) Extreme winds;

h) Cloud bursts; and

j) Failure of slopes.

A study of the earthquake, wind/cyclone and flood hazard maps of India indicate that there are several areas in the country which run the risk of being affected by more than one of these hazards.

Further there may be instances where one hazard may cause occurrence or accentuation of another hazard such as landslides may be triggered/accelerated by earthquakes and wind storms and floods by the cyclones.

It is important to study and examine the possibility of occurrence of multiple hazards, as applicable to an area. However, it is not economically viable to design all the structures for multiple hazards. The special structures such as nuclear power plants and life line structures such as hospitals and emergency rescue shelters may be designed for multiple hazards. For such special structures, site specific data have to be collected and the design be carried out based on the accepted levels of risk. The factors that have to be considered in determining this risk are:

a) The severity of the hazard characterized by M.M. (or M.S.K.) intensity in the case of earthquake; the duration and velocity of wind in the storms; and unprotected or protected situation of flood prone areas; and

b) The frequency of occurrence of the severe hazards.

Till such time that risk evaluation procedures are formalized, the special structures may be designed for multiple hazards using the historical data, that can be obtained for a given site and the available code for loads already covered. The designer may have to consider the loads due to any one of the hazards individually or in combination as appropriate.

10.2 Multi-hazard Prone Areas

10.2.1 At a site, more than one hazard may be prominent. In general, the natural hazards are not considered to act together, but need to be considered one at a time. Also, the proportion of combining the man-made hazards with natural hazards also are specified in the NBC. The NBC provides a minimum set of combinations of loads that need to be considered in the design of structures along with the corresponding partial safety factor of the loads in each of the said combinations.

10.2.2 The criteria adopted for identifying multi hazard prone areas may be as follows:

a) *Earthquake and flood risk prone* — Districts which have seismic zone of intensity 7 or more and also flood prone unprotected or protected area. Earthquake and flood can occur separately or simultaneously.

b) *Cyclone and flood risk prone* — Districts which have cyclone and flood prone areas. Here floods can occur separately from cyclones, but simultaneous also along with possibility of storm surge too.

c) *Earthquake, cyclone and flood risk prone* — Districts which have earthquake zone of intensity 7 or more, cyclone prone as well as flood prone (protected or unprotected) areas. Here the three hazards can occur separately and also simultaneously as in (a) and (b) above but earthquake and cyclone will be assumed to occur separately only.

d) *Earthquake and cyclone risk prone* — Districts which have earthquake zone of intensity 7 or more and prone to cyclone hazard too. The two will be assumed to occur separately.

Based on the approach given above, the districts with multi-hazard risk are given in Annex M.

10.3 Use of the List of the District with Multi-Hazard Risk

The list provides some ready information for use of the authorities involved in the task of disaster mitigation, preparedness and preventive action. This information gives the districts which are prone to high risk for more than one hazard. This information will be useful in establishing the need for developing housing design to resist such multi-hazard situation.

11 DOCUMENTATION

11.1 For the successful planning, design and construction of buildings, adequate documentation covering structural design sufficiency, sub-surface investigations, supervision, etc may be required. In particular, compliance with the structural safety requirements of this NBCS shall be demonstrated through appropriate documentation, including the preparation of a Structural Design Basis Report (SDBR), which establishes the basis and assumptions adopted in the structural design.

11.2 Structural Design Basis Report (SDBR)

The Structural design basis report (SDBR) is a document that establishes the basis and assumptions adopted for the structural design of high rise and special buildings, demonstrating that the structure has been designed to ensure safety against various loads, actions and effects, including those arising from natural hazards such as earthquakes, landslides, cyclones and floods, in accordance with the provisions of this NBCS, particularly Part C 'Structural Design' and other relevant Indian Standards.

The preparation and submission of an SDBR provides transparency and traceability of design decisions and enables verification that the structural system, materials, loading criteria and analysis methods adopted are consistent with the applicable provisions. It also serves as a reference document for reviewing authorities and stakeholders and ensures that the registered engineer/structural engineer maintains adequate documentation to substantiate the structural design.

The SDBR (Annex N) sets out the basis for designing the building and consists of the following parts:

a) Part 1 — General information/Data;

b) Part 2 — Load-bearing masonry buildings;
c) Part 3 — Reinforced concrete buildings; and
d) Part 4 — Steel and steel–concrete composite buildings.

For demonstrating compliance with Part C ‘Structural Design’ of this NBCS and the relevant Indian Standards referenced therein, the registered engineer/structural engineer shall submit an SDBR for structures of different complexities along with the drawings and other documents required to be submitted with the application.

ANNEX A

[*Foreword*, *Clause* 2.2]

DEAD LOADS — UNIT WEIGHTS OF CONSTRUCTION MATERIAL AND STORED MATERIALS

A-1 BUILDING MATERIALS

The unit weight of materials used in construction of buildings and structures are specified in Table 40. Also mentioned alongside are the corresponding Indian Standards, if applicable

Table 40 Unit Weight of Building Materials

(*Clause* A-1)

Sl No.	**Materials**	**Nominal Size or Thickness** mm	**Weight**	
			kN	per
(1)	(2)	(3)	(4)	(5)
i)	**Acoustical Material (*see* IS 2526) [C-1(15)]**			
	Eelgrass	10	0.57 to 0.765 × 10^{-2}	m^{2}
	Glass fibre, min	10	0.38 × 10^{-2}	m^{2}
	Hair	10	1.91 × 10^{-2}	m^{2}
	Mineral wool	10	1.345 × 10^{-2}	m^{2}
	Slag wool		2.65	m^{3}
	Cork		2.35	m^{3}
	Wood fibre board		5.9 to 6.15	m^{3}
	Wood particle Board			
	As per IS 3129 [C-1(15)]		3.92	m^{3}
	As per IS 12823 [C-1(15)]		4.9 to 9.9	m^{3}
	As per IS 3478 [C-1(15)]		8.9 to 11.8	m^{3}
	Compressed wood wool	-	3.95 to 4.45	m^{3}
	Mineral/glass wool quilts and mats	-	0.157 to 0.314	m^{3}
	Mineral compressed glass wool tiles	-	1.87 to 2.06	m^{3}
	Polyester board	-	1.87 to 2.06	m^{3}
ii)	**Aggregate, Coarse**			
	Broken stone ballast			
	Dry, well-shaken	–	15.70 to 18.35	m^{3}
	Perfectly wet	–	18.85 to 21.95	m^{3}
	Shingles, 3 to 38 mm	–	14.35	m^{3}
	Broken bricks:			
	Fine	–	14.20	m^{3}

	Coarse	–	9.90	m^3
	Foam slag (foundry pumice)	–	6.85	m^3
	Cinder	–	7.85	m^3
	Slag			
	Iron slag		32.4	m^3
	Steel Slag		31 to 36	m^3
	Copper slag		31 to 36	m^3
	River pebbles		15	m^3
iii)	**Aggregate, Fine**			
	Sand			
	Dry, clean	–	15.10 to 15.70	m^3
	River	–	18.05	m^3
	Wet	–	17.25 to 19.60	m^3
	Brick dust (*SURKHI*)	–	9.90	m^3
	Crushed stone sand (*see* IS 383) [C-1(15)]		19 to 20	m^3
	Quarry dust		14 to 20	m^3
iv)	**Aggregate, Organic**			
	Saw dust, loose	–	1.55	m^3
	Peat			
	Dry	–	5.50 to 6.30	m^3
	Sandy, compact	–	7.85	m^3
	Wet, compact	–	13.35	m^3
v)	**Asbestos**			
	Felt	10	0.145	m^2
	Fibres:			
	Pressed	–	9.40	m^3
	Sprayed	10	0.02	m^2
	Natural	–	29.80	m^3
	Raw	–	5.90 to 8.85	m^3
vi)	**Asbestos Cement Building Pipes** (*see* Sl No. xliii ‘pipes’ in this Table)			
vii)	**Asbestos Cement Gutters** [*see* IS 1626 (Part 2)] [C-1(15)]			
	Boundary wall gutters			
	510 mm × 150 mm × 255 mm	12.5	0.180	m
	455 mm × 150 mm × 305 mm	12.5	0.158	m
	305 mm × 150 mm × 225 mm	12.5	0.129	m
	280 mm × 125 mm × 180 mm	12.5	0.106	m
	Valley gutters			

	915 mm × 205 mm × 230 mm	12.5	0.250	m
	610 mm × 150 mm × 230 mm	12.5	0.162	m
	455 mm × 125 mm × 150 mm	12.5	0.146	m
	405 mm × 125 mm × 255 mm	12.5	0.131	m
	Half round gutters			
	150 mm	9.5	0.043	m
	230 mm	9.5	0.073	m
	305 mm	9.5	0.088	m
viii)	**Asbestos Cement Pressure Pipes** (*see* Sl No. xliii 'Pipes' in this Table)			
ix)	**Asbestos Cement Sheeting** (*see* IS 459) [C-1(15)]			
	Corrugated (pitch – 146 mm)	6	0.118 to 0.130	m^2
	Semi-corrugated (pitch 388 mm)	6	0.118 to 0.127	m^2
	Plain	5	0.09	m^2
x)	**Bitumen**	–	0.8-1	m^3
xi)	**Binders**			
	Fly Ash loose		5.05 to 7.05	m^3
	Fly Ash compacted		16.00	m^3
	Ground Granulated blast furnace slag		14.9	m^3
	Silica fume		3.5 to 7	m^3
	Rice husk ash		1.0 to 3.5	m^3
	Metakaolin		8 to 10	m^3
xii)	**Blocks**			
	Lime-based solid blocks (*see* IS 3115) [C-1(15)], *min*	–	9.8	m^3
	concrete blocks [*see* IS 2185 (Part 1)] [C-1(15)]			
	Grade A (hollow)	–	15	m^3
	Grade B (hollow)	–	11 to 15	m^3
	Grade C (Solid)	–	18	m^3
	Autoclaved cellular concrete blocks [*see* IS 2185 (Part 3)] [C-1(15)]		4.42 to 9.81	m^3
xiii)	**Boards**			
	Cork boards [*see* IS 4253 (Part 1 and Part 2)] [C-1(15)]			
	Compressed		2.16 to 3.73	m^3
	Ordinary		2.15 to 3.72	m^3
	Fibre hard boards (*see* IS 1658) [C-1(15)]			

	Medium hardboard		3.43 to 7.84	m^3
	Standard hardboard		7.84 to 10.05	m^3
	Tempered hardboard		7.84 to 10.05	m^3
	Fibre cement boards (*see* IS 14862) [C-1(15)]		13 to 16	m^3
	Fibre insulation board, ordinary or flame-retardant type bitumen-bounded fibre insulation board (*see* IS 3348*)* [C-1(15)], *Max*	9, 12, 18, 25	3.924	M^3
	Plain gypsum plaster boards [*see* IS 2095 (Part 1)] [C-1(15)]			
	Type A	9.5, 12.5, 15	5.39	m3
	Type H1 and H2	9.5, 12.5, 15	5.88	m3
	Type D	9.5, 12.5, 15	7.84	m3
	Type F and FH	9.5, 12.5, 15	7.84	m3
	Type R1	9.5, 12.5, 15	8.33	m3
	Type R2	9.5, 12.5, 15	9.31	m3
	Type W	9.5, 12.5, 15	8.33	m3
	Coated/laminated gypsum plaster boards [*see* IS 2095 (Part 2)] [C-1(15)]	9.5, 12.5, 15	11.27	M^3
	Reinforced gypsum plaster boards and ceiling tiles [*see* IS 2095 (Part 3)] [C-1(15)], *min*			
	Fibre reinforced Gypsum		7.84	m^3
	Glass reinforced Gypsum plaster board		24.52	m^3
	Glass reinforced Gypsum plaster tiles		5.88	m^3
	Insulating board (*fibre*) (*see* IS 3348) [C-1(15)], *mean*		0.981	m^3
	Laminated board (*fibre*) Medium density (*see* IS 14587) [C-1(15)]		5.88 to 8.82	m^3
	Wood particle boards (*see* IS 3087) [C-1(15)]	–	4.90 to 8.85	m^3
	Low density wood particles boards for insulation purposes (*see* IS 3129) [C-1(15)]	–	3.52	m^3
	High density wood particle boards (*see* IS 3478) [C-1(15)]			
	Type 1 & 2, Grade A	–	11.30	m^3
	Type 1 & 2, Grade B	–	7.94	m^3

xiv)	**Bricks**			
	Common burnt clay bricks (*see* IS 1077) [C-1(15)]	–	15.70 to 18.85	m^3
	Engineering bricks	–	21.20	m^3
	Heavy duty bricks (*see* IS 2180) [C-1(15)]	–	24.50	m^3
	Pressed bricks	–	17.25 to 18.05	m^3
	Refractory bricks	–	17.25 to 19.60	m^3
	Sand cement bricks	–	18.05	m^3
	Sand lime bricks	–	20.40	m^3
	Pulverized fuel-ash lime bricks (*see* IS 12894) [C-1(15)]		12 to 15	m^3
	Pulverized fuel-ash cement bricks (*see* IS 16720) [C-1(15)]		10.8 to 19.6	m^3
	Acid resistance bricks (*see* IS 4860) [C-1(15)]		22.5 to 24.83	m^3
	Soil based bricks (*see* IS 1725) [C-1(15)]		17.5	m^3
	Perforated building bricks (*see* IS 2222) [C-1(15)]		6.8 to 7.75	m^3
	Calcium silicate bricks (*see* IS 4139) [C-1(15)]		25 to 29	m^3
xv)	**Brick Chips and Broken Bricks** (*see* under Sl No. ii 'Broken Bricks' in this Table)			
xvi)	**Brick dust (*SURKHI*)**	–	9.00	m^3
xvii)	**Cast Iron, Manhole Covers** (*see* IS 1726) [C-1(15)]			
	Double triangular (HD)	500	1.16	Cover
		560	1.37	Cover
	Circular (HD)	500	1.16	Cover
		560	1.37	Cover
	Circular (MD)	500	0.57	Cover
		560	0.63	Cover
	Rectangular (MD)	–	0.78	Cover
	Rectangular (LD) :			
	Single seal (Pattern 1)	–	0.23	Cover
	Single seal (Pattern 2)	–	0.15	Cover
	Double seal	–	0.28	Cover
	Square (LD):			
	Single seal	455	0.13	Cover
		610	0.25	Cover
	Double seal	455	0.23	Cover
		610	0.36	Cover

xviii)	**Cast Iron, Manhole Frames** (*see* IS 1726) [C-1(15)]			
	Double triangular (HD)	500	1.09	Frame
		560	1.13	Frame
	Circular (HD)	500	0.83	Frame
		560	1.06	Frame
	Circular (MD)	500	0.57	Frame
		560	0.63	Frame
	Rectangular (MD)	–	0.63	Frame
	Rectangular (LD):			
	Single seal (Pattern 1)	–	0.15	Frame
	Single seal (Pattern 2)	–	0.10	Frame
	Double seal	–	0.23	Frame
	Square (LD):			
	Single seal	455	0.07	Frame
		610	0.13	Frame
	Double seal	455	0.15	Frame
		610	0.18	Frame
xix)	**Cast Iron Pipes** (*see* under Sl No. xliii 'Pipes' in this Table)			
xx)	**Cement**			
	Ordinary (*see* IS 269) and other types	–	14.10	m^3
	Rapid-hardening (*see* IS 8041) [C-1(15)]	–	12.55	m^3
xxi)	**Ceilings**			
	Plaster on tile or concrete	13 mm thick	0.25	m^2
	Plaster on wood lath	25 mm thick	0.39	m^2
	Suspended metal lath and cement plaster	25 mm thick	0.74	m^2
	Suspended metal lath and gypsum plaster	25 mm thick	0.49	m^2
xxii)	**Cement Concrete, Plain**			
	Aerated		7.45	m^3
	No-fines, with heavy aggregate	–	15.70 to 18.80	m^3
	No-fines, with light aggregate	–	8.65 to 12.55	m^3
	With burnt clay aggregate	–	17.25 to 21.20	m^3
	With expanded clay aggregate	–	9.40 to 16.50	m^3
	With clinker aggregate	–	12.55 to 17.25	m^3
	With pumice aggregate	–	5.50 to 11.00	m^3
	With sand and gravel or crushed natural stone aggregate	–	22.00 to 23.50	m^3

	With saw dust	–	6.30 to 16.50	m^3
	With foamed slag aggregate	–	9.40 to 18.05	m^3
	With light weight cinder aggregate		6.4	m^3
	Light weight concrete		8 to 20	m^3
	Cellular concrete (Foam concrete) (*see* IS 6598) [C-1(15)]		3 to 5	m^3
	Grade A, *max*		3.13	m^3
	Grade B		3.13 to 3.92	m^3
	Grade C		3.93 to 4.9	m^3
	Transparent concrete		15	m^3
	Glass fiber reinforced concrete		18 to 22	m^3
	Alkali activated (Geopolymer) concrete (*see* IS 17452) [C-1(15)]		24 to 25	m^3
	Shotcrete (*see* IS 9012) [C-1(15)]		22 to 25	m^3
	Ferro cement		22 to 25	m^3
	Roller compacted concrete		22 to 25	m^3
	Controlled low strength mix		22 to 25	m^3
	Plum concrete (*see* IS 457) [C-1(15)]		22 to 25	m^3
	Autoclaved Aerated Concrete		4.42 to 9.81	m^3
	Vermiculite concrete		6 to 9	m^3
xxiii)	**Cement Concrete, Prestressed** (conforming to IS 1343) [C-1(15)]	–	23.50	m^3
xxiv)	**Cement Concrete, Reinforced:**			
	With 1 percent steel	–	22.75 to 24.20	m^3
	With 2 percent steel	–	23.25 to 24.80	m^3
	With 5 percent steel	–	24.80 to 26.50	m^3

		200	1.96	m^2
	NOTE — Add extra for concrete topping.			
	Hollow concrete units including any concrete topping necessary for constructional purposes	100	1.67	m^2
		125	1.96	m^2
		150	2.16	m^2
		175	2.35	m^2
		200	2.65	m^2
		230	3.14	m^2
	Floors, wood:			
	Hard wood	22	0.16	m^2
		28	0.20	m^2
	Soft wood	22	0.11	m^2
		28	0.13	m^2
	Weight of mastic used in laying wood block flooring	–	0.015	m^2
	NOTE — All thicknesses are ‘finished thicknesses’.			
	Floor finishes:			
	Clay floor tiles (*see* IS 1478) [C-1(15)]	12.5 to 25.4	0.10 to 0.2	m^2
	NOTE – This weight is ‘as laid’ but excludes screeding.			
	Magnesium oxychloride:			
	Normal type (saw dust filler)	10	0.142	m^2
	Heavy duty type (mineral filler)	10	0.216	m^2
	Parquet flooring	–	0.08 to 0.12	m^2
	Rubber (*see* IS 809) [C-1(15)]	3.2	0.048 to 0.062	m^2

		4.8	0.070 to 0.09	m^2
		6.4	0.093 to 0.130	m^2
	Terra cotta, filled 'as laid'	–	5.54 to 7.06	m^2
	Terrazzo paving 'as laid'	10	0.23	m^2
xxxii)	**Foam Slag, Foundry Pumice**	–	6.85	m^3
xxxiii)	**Gutters, Asbestos Cement** (*see* under vii '**Asbestos cement gutter**' in this Table)			
xxxiv)	**Gypsum**			
	Gypsum mortar [*see* IS 2547 (Part 1 and Part 2)] [C-1(15)]	–	18.6	m^3
	Gypsum powder (*see* IS 12679) [C-1(15)]	–	13.89 to 17.25	m^3
xxxv)	**Iron**			
	Pig	–	70.60	m^3
	Gray, cast	–	68.95 to 69.90	m^3
	White, cast	–	74.30 to 75.70	m^3
	Wrought	–	75.70	m^3
xxxvi)	**Lime**			
	Lime concrete with burn clay Aggregate (*see* IS 2541) [C-1(15)]	–	18.80	m^3
	Lime mortar	–	15.70 to 18.05	m^3
	Lime plaster (*see* IS 2394) [C-1(15)]	–	17.25	m^3
	Lime stored in lumps, uncalcined	–	12.55 to 14.10	m^3
	Lime, unslaked, freshly burnt in pieces	–	8.60 to 10.20	m^3
	Lime slaked, fresh	–	5.70 to 6.30	m^3
	Lime slaked, after 10 days	–	7.85	m^3
	Lime, unslaked (KANKAR)	–	11.55	m^3
	Lime, slaked (KANKAR)	–	10.00	m^3
xxxvii)	**Linoleum** (*see* IS 653) [C-1(15)]			
	Sheets and tiles	4.5	0.0569	m^2
		3.2	0.0402	m^2
		2.0	0.0265	m^2
		1.65	0.0215	m^2
xxxviii)	**Masonry**			
	Brick Masonry (excluding plaster)			
	With common burnt clay bricks (*see* IS 1077) [C-1(15)]	–	19.25	m^3

	Engineering bricks	–	21.2	m^3
	Glazed bricks	–	20.40	m^3
	Pressed bricks	–	18.65	m^3
	Block Masonry			
	With lime based solid blocks		13.55	m^3
	Hollow concrete blocks			
	Grade A		15.4	m^3
	Grade B		12.00	m^3
	Solid Concrete Blocks		18.15	m^3
	Autoclaved cellular concrete blocks		9.1 to 11.1	m^3
xxxix	**Masonry, Stone**			
	Cast	–	21.75	m^3
	Dry rubble	–	20.40	m^3
	Granite ashlar	–	25.00	m^3
	Granite rubble	–	23.55	m^3
	Lime stone ashlar	–	25.10	m^3
	Marble dressed	–	26.50	m^3
	Sand stone	–	22.00	m^3

xlviii)	**Soils and Gravels**			
	Alluvial ground, undisturbed	–	15.69	m^3
	Broken stone ballast:			
	Dry, well-shaken	–	15.70 to 18.35	m^3
	Perfectly wet	–	18.85 to 21.95	m^3
	Chalk		15.70 to 18.85	m^3
	Clay:			
	China, compact	–	21.95	m^3
	Clay fills:			
	Dry, lumps	–	10.20	m^3
	Dry, compact	–	14.10	m^3
	Damp, compact	–	17.25	m^3
	Wet , compact	–	20.40	m^3
	Undisturbed	–	18.85	m^3
	Undisturbed, gravelly	–	20.40	m^3
	Crush stone sand (Msand)	–	–	–
	Earth:			
	Dry	–	13.85 to 18.05	m^3
	Moist	–	15.70 to 19.60	m^3
	Gravel:			
	Loose	–	15.70	m^3
	Rammed	–	18.85 to 21.20	m^3
	Kaolin, compact	–	25.50	m^3
	Loam:			
	Dry, loose	–	11.75	m^3
	Dry, compact	–	15.70	m^3
	Wet, compact	–	18.85	m^3
	Loess, dry	–	14.10	m^3
	Marl, compact	–	17.25 to 18.85	m^3
	Mud, river, wet	–	17.25 to 18.85	m^3
	Peat:			
	Dry	–	5.50 to 6.30	m^3
	Sandy, compact	–	7.85	m^3
	Wet, compact	–	13.35	m^3
	Rip-rap	–	12.55 to 14.10	m^3
	Sand:			
	Dry, clean	–	15.10 to 15.70	m^3

	River	–	18.05	m^3
	Wet	–	17.25 to 19.60	m^2
	Shingles:			
	Aggregate 3 to 38 mm	–	13.75	m^2
	Fine sand:			
	Dry	–	15.70	m^2
	Saturated	–	20.40	m^2
	Silt, wet	–	17.25 to 18.85	m^2
xlix)	**Steel sections**			
	Density of steel sections shall be taken as 78.50 kg/m^3			
	Weight of hot rolled sections (ISJB, ISLB, ISMB, ISWB, ISNPB, ISWPB, ISSC, ISHB, ISJC, ISLC, ISMC, ISMPC, ISA, ISPBP) shall be referred from (*see* IS 808) [C-1(15)]			
	Weight of hollow steel sections shall be referred from (*see* IS 4923) [C-1(15)]			
	Weight of cold formed light gauge structural steel sections shall be referred from (*see* IS 811) [C-1(15)]			
	Weight of rolled and slit T bars shall be referred from (*see* IS 1173) [C-1(15)]			
	Weight of steel sheet piling sections shall be referred from (*see* IS 2314) [C-1(15)]			
l)	**Stone**			
	Agate	–	25.50	m^3
	Aggregate	–	15.70 to 18.85	m^3
	Basalt	–	27.95 to 29.05	m^3
	Cast	–	21.95	m^3
	Chalk	–	21.50	m^3
	Dolomite	–	28.25	m^3
	Emery	–	39.25	m^3
	Flint	–	25.40	m^3
	Gneiss	–	23.55 to 26.40	m^3
	Granite	–	25.90 to 27.45	m^3
	Gravel:			
	Loose	–	15.70	m^3
	Moderately rammed, dry	–	18.85	m^3
	Green stone	–	28.25	m^3
	Gypsum	–	21.95 to 23.55	m^3
	Kota			
	Laterite	–	20.40 to 23.55	m^3
	Lime stone	–	23.55 to 25.90	m^3
	Marble	–	26.70	m^3
	Pumice	–	7.85 to 11.00	m^3
	Quartz rock	–	25.90	m^3

	Sand stone	–	21.95 to 23.54	m^3
	Slate	–	27.45	m^3
	Soap stone	–	26.45	m^3
li)	**Tar, Coal**			
	Crude (*see* IS 212) [C-1(15)]	–	9.90	m^3
	Naphtha, light	–	9.90	m^3
	Naphtha, heavy	–	9.90	m^3
	Road tar	–	9.90	m^3
	Pitch (*see* IS 216) [C-1(15)]	–	9.90	m^3
lii)	**Thermal Insulation**			
	Unbonded glass wool	–	12.75 to 23.55	m^3
	Unbonded rock and slag wool	–	11.30 to 19.60	m^3
	Cellular concrete			
	Grade A	–	Up to 29.40	m^3
	Grade B	–	29.50 to 39.20	m^3
	Grade C	–	39.30 to 49.00	m^3
	Performed calcium silicate Insulation (for temperature up to 650°C)	–	19.60 to 34.30	m^3
liii)	**Tiles and stone cladding**			
	Terra-cotta	–	18.35 to 23.25	m^2
	Terrozzo			
	Paving	10	0.24	m^2
	Cast partitions	40	0.93	m^2
	Tiles			
	Mangalore pattern (*see* IS 654) [C-1(15)]	–	0.02 to 0.03	Tile
	Polystyrene wall tiles	99 x 99	0.013	m^2
		148.5 x 148.5	0.013	m^2
	Pressed ceramic tiles, glazed and unglazed (*see* IS 15622) [C-1(15)]		22	m^3
	Concrete paving blocks (*see* IS 15658) [C-1(15)]		24	m^3
liv)	**Timber**			
	Typical Indian timbers (*see* IS 399) [C-1(15)]			
	Aglaia	–	8.34	m^3
	Aini	–	5.83	m^3
	Alder	–	3.63	m^3
	Amari	–	6.13	m^3

	Amla	–	7.85	m^3
	Amra	–	4.41	m^3
	Anjan	–	8.33	m^3
	Arjun	–	7.99	m^3
	Ash	–	7.06	m^3
	Axlewood	–	8.82	m^3
	Babul	–	7.70	m^3
	Baen	–	7.70	m^3
	Bahera	–	7.99	m^3
	Bakota	–	4.21	m^3
	Balasu	–	7.55	m^3
	Ballagi	–	11.13	m^3
	Bamboo			
	Banati	–	4.41	m^3
	Benteak	–	6.62	m^3
	Ber	–	6.91	m^3
	Bhendi	–	7.55	m^3
	Bijasal	–	7.85	m^3
	Black chuglam	–	6.13	m^3
	Birch	–	7.85	m^3
	Black locust	–	8.34	m^3
	Blue gum	–	8.34	m^3
	Blue pine	–	5.05	m^3
	Bola	–	6.42	m^3
	Bonsum	–	5.20	m^3
	Bullet wood	–	8.78	m^3
	Casuarina	–	8.34	m^3
	Cettis	–	6.42	m^3
	Champ	–	4.85	m^3
	Chaplash	–	5.05	m^3
	Chatian	–	4.07	m^3
	Chikrassy	–	6.62	m^3
	Chilauni	–	6.42	m^3
	Chilla	–	7.85	m^3
	Chir	–	5.64	m^3
	Chuglam:			
	Black	–	7.85	m^3
	White (silver grey-wood)	–	6.91	m^3

	Cinnamon	–	6.42	m^3
	Cypress	–	5.05	m^3
	Debdaru	–	6.28	m^3
	Deodar	–	5.35	m^3
	Devdam	–	7.06	m^3
	Dhaman:			
	Grewia tiliofolia	–	7.70	m^3
	Grewia vestita	–	7.40	m^3
	Dhup	–	6.42	m^3
	Dilenia	–	6.13	m^3
	Dudhi	–	5.49	m^3
	Ebony	–	8.19	m^3
	Elim	–	5.20	m^3
	Eucalyptus	–	8.33	m^3
	Figs	–	4.56	m^3
	Fir	–	4.14	m^3
	Frash	–	6.62	m^3
	Gamari	–	5.05	m^3
	Gardenia	–	7.40	m^3
	Garuga	–	5.98	m^3
	Geon	–	4.07	m^3
	Gluta	–	7.06	m^3
	Gokul	–	4.07	m^3
	Grewia sp.	–	7.55	m^3
	Gurjan	–	7.70	m^3
	Gutel	–	4.41	m^3
	Haldu	–	6.62	m^3
	Hathipaila	–	5.84	m^3
	Hiwar	–	7.70	m^3
	Hollock	–	5.98	m^3
	Hollong	–	7.21	m^3
	Hoom	–	7.21	m^3
	Horse chestnut	–	5.05	m^3
	Imli	–	8.97	m^3
	Indian Chestnut	–	6.28	m^3
	Indian Hemlock	–	3.92	m^3
	Indian Oak	–	8.48	m^3
	Indian Olive	–	10.35	m^3

	Irul	–	8.33	m^3
	Jack	–	5.83	m^3
	Jaman	–	7.70	m^3
	Jarul	–	6.13	m^3
	Jathtkai	–	5.05	m^3
	Jhingan	–	5.63	m^3
	Jutili	–	7.85	m^3
	Kadam	–	4.85	m^3
	Kail	–	5.05	m^3
	Kaim	–	6.42	m^3
	Kambli	–	4.07	m^3
	Kanchan	–	6.62	m^3
	Kanjuj	–	5.84	m^3
	Karada	–	8.34	m^3
	Karal	–	7.99	m^3
	Karani	–	6.28	m^3
	Karar	–	5.34	m^3
	Kardahi	–	9.27	m^3
	Karimgotta	–	3.92	m^3
	Kasi	–	5.83	m^3
	Kasum	–	10.84	m^3
	Kathal	–	5.85	m^3
	Keora	–	6.13	m^3
	Khair	–	9.00	m^3
	Khasipine	–	5.05	m^3
	Kindal	–	7.55	m^3
	Kokko	–	6.28	m^3
	Kongoo	–	9.76	m^3
	Kuchla	–	8.63	m^3
	Kumbi	–	7.70	m^3
	Kurchi	–	5.20	m^3
	Kurung	–	9.76	m^3
	Kusum	–	11.28	m^3
	Kuthan	–	4.71	m^3
	Lakooch	–	6.28	m^3
	Lambapatti	–	5.34	m^3
	Lampati	–	5.05	m^3
	Laurel	–	8.33	m^3

	Lendi	–	7.40	m^3
	Machilus:			
	Gamblei	–	5.05	m^3
	Macrantha	–	5.20	m^3
	Maharukh	–	4.07	m^3
	Mahogany	–	6.62	m^3
	Mahua	–	8.97	m^3
	Maina	–	5.64	m^3
	Makai	–	3.14	m^3
	Malabar neem	–	4.41	m^3
	Mango	–	6.77	m^3
	Maniawga	–	7.40	m^3
	Maple	–	5.64	m^3
	Mesua	–	9.76	m^3
	Milla	–	9.12	m^3
	Mokha	–	7.99	m^3
	Mulberry	–	6.62	m^3
	Mullilam	–	7.21	m^3
	Mundani	–	6.77	m^3
	Murtenga	–	7.70	m^3
	Myrabolan	–	9.27	m^3
	Narikel	–	5.49	m^3
	Nedunar	–	5.05	m^3
	Oak	–	8.48	m^3
	Padauk	–	7.06	m^3
	Padri	–	7.06	m^3
	Palang	–	5.98	m^3
	Pali	–	6.28	m^3
	Papita	–	3.28	m^3
	Parrotia	–	8.48	m^3
	Persian lilac	–	5.84	m^3
	Piney	–	6.13	m^3
	Ping	–	8.97	m^3
	Pinus insignis	–	6.13	m^3
	Pipli	–	5.83	m^3
	Pitraj	–	6.77	m^3
	Poon	–	6.42	m^3
	Poplar	–	4.41	m^3

	Pula	–	3.78	m^3
	Pyinma	–	3.98	m^3
	Rajbrikh	–	8.48	m^3
	Red sanders	–	10.84	m^3
	Rohini	–	11.33	m^3
	Rosewood (black wood)	–	8.19	m^3
	Rudrak	–	4.71	m^3
	Sal	–	8.48	m^3
	Salai	–	5.64	m^3
	Sandal wood	–	8.97	m^3
	Sadan	–	8.34	m^3
	Satin wood	–	9.41	m^3
	Saykaranji	–	7.40	m^3
	Seleng	–	4.85	m^3
	Semul	–	3.78	m^3
	Silver oak	–	6.28	m^3
	Siris	–	3.92	m^3
	Kala-siris	–	7.21	m^3
	Safed- siris	–	6.28	m^3
	Siaso	–	7.70	m^3
	Spruce	–	4.71	m^3
	Suji	–	2.65	m^3
	Sundri	–	9.41	m^3
	Talauma	–	5.64	m^3
	Tanaku	–	2.09	m^3
	Teak	–	6.28	m^3
	Toon	–	5.05	m^3
	Udal	–	2.50	m^3
	Upas	–	3.14	m^3
	Uriam	–	7.40	m^3
	Vakai	–	9.41	m^3
	Vellapine	–	5.83	m^3
	Walnut	–	5.64	m^3
	White bombwe	–	5.98	m^3
	White cedar	–	7.06	m^3
	White chuglam (silver grey-wood)	–	6.91	m^3
	White dhup	–	4.22	m^3
	Yon	–	8.33	m^3

	NOTE — The unit of timbers correspond to average unit of typical Indian timbers at 12 percent moisture content.			
lv)	**Water**			
	Fresh	–	10.0	m³
	Salt	–	10.05	m³
lvi)	**Wood – Wool Building Slabs**	10mm	0.059	m²
lvii)	**Walling** (*see* IS 6072) [C-1(15)]			
	Autoclaved reinforced cellular concrete wall slabs			
	Class A	–	8.35 to 9.80	m²
	Class B	–	7.35 to 8.35	m²
	Class C	–	6.35 to 7.35	m²
	Class D	–	5.40 to 6.35	m²
	Class E	–	4.40 to 5.40	m²
	Brick masonry (*see* xxxviii 'Masonry Brick' in Table 1)			
	Blocks masonry (*see* xii 'Block' in Table 1)			
	Stone masonry (*see* xxxix 'Masonry Stone' in Table 1)			
	Partitions 39			
	Brick wall	100	1.91	m²
	Cinder concrete	75	1.13	m²
	Galvanized on sheet	–	0.15	m²
	Hollow glass block (bricks)	100	0.88	m²
	Hollow blocks per 200 mm of thickness			
	Ballast or stone concrete	200	0.201	m²
	Clay	200	0.201	m²
	Clinker concrete	200	0.220	m²
	Coke breeze concrete	200	9.176	m²
	Diatomaceous earth	200	0.093	m²
	Gypsum	200	0.137	m²
	Pumice concrete	200	0.177	m²
	Slag concrete, air-cooled	200	0.196	m²
	Slag concrete foamed	200	0.186	m²
	Lath and plaster	–	0.392	m²
	Solid blocks per 20 mm of thickness			
	Ballast or stone	20	0.451	m²
	Clinker concrete	20	0.300	m²
	Coke breeze concrete	20	0.221	m²
	Pumice concrete	20	0.221	m²
	Slag concrete, foamed	20	0.250	m²
	Terrazzo cast partitions	40	0.932	m²
	Timber studding plastered	–	9.981	m²
NOTE — For unit weight of fixtures and fittings required to buildings including builder's hardware, reference may be made to appropriate Indian standards.				

A-2 STORED AND MISCELLANEOUS MATERIALS

A-2.1 Units weights of stored and miscellaneous materials intended for dead load calculation and other general purposes are given in Table 41.

Table 41 Unit Weights of Stored and Miscellaneous Materials

(*Clause* A-2.1)

Sl No.	Materials	Weight KN/m^3	Angle of Friction, Degrees
(1)	(2)	(3)	(4)
i)	**Agriculture and Food Products**		
	Butter	8.45	–
	Coffee in bags	5.50	–
	Drinks in bottle, in boxes	7.35	–
	Eggs, packed	2.95	–
	Fats, oil	5.80	–
	Fish meal	4.90	45
	Flour in sacks up to 1 m height	2.20 to 5.90	–
	Forage (bales)	1.25	–
	Fruits	3.45	–
	Grains:		
	Barley	6.75	27
	Corn, shelled	7.55	27
	Flax seed	7.35	30
	Oats	5.30	30
	Rice	6.55	33
	Soyabeans	7.35	30
	Wheat	8.15	28
	Wheat flour	6.85	30
	Grain sheaves up to 4 m stack height	0.98	30
	Grain sheaves over 4 m stack height	1.45	30
	Grass and clover	3.45	–
	Hay:		–
	Compressed	1.65	–
	Loose up to about 3 m stack height	0.69	–
	Honey	14.10	–
	Hops:		
	In stacks	1.65	–
	In cylinder hop bins	4.60	–

Table 41 (*Continued*)

Sl No.	Materials	Weight KN/m^3	Angle of Friction, Degrees
(1)	(2)	(3)	(4)
	Sewn up or compressed in cylindrical shape in hop cloth	2.85	–
	Malt:		
	Crushed	3.90	20
	Germinated	1.85	–
	Meat and meat products	7.05	–
	Milk	10.05	–
	Molasses	4.40	–
	Onion in bags	5.40	0
	Oil cakes, crushed	5.80	0
	Potatoes	7.05	30
	Preserves (tins in cases)	4.90 to7.85	–
	Bags	7.05	–
	Bulk	9.40	–
	Seeds:		
	Heaps	4.90 to 7.85	25
	Sacks	3.90 to 6.85	–
	Straw and chaff:		
	Loose up to about 3 m stack height	0.45	–
	Compressed	1.65	–
	Sugar:		
	Crystal	7.35	30
	Cube sugar in boxes	7.85	–
	Sugar beet, pressed out	7.85	–
	Tobacco bundles	3.45	–
	Vinegar	10.40	–
ii)	**Chemicals and Allied Materials**		
	Acid, hydrochloric	11.75	–
	Acid, nitric 91 percent	14.80	–
	Acid, sulphuric 87 percent	17.55	–
	Alcohol	7.65	–
	Alum, pearl in barrel	5.20	–
	Ammonia, liquid	8.85	–
	Ammonium, chloride, crystalline	8.15	30 to 40
	Ammonium nitrate	7.05 to 9.80	25
	Ammonium sulphate	7.05 to 9.00	32 to 45
	Beeswax	9.40	–
	Benzole	8.90	–
	Benzene hexachloride	8.75	–
	Bicarbonate of soda	6.40	–

Table 41 (*Continued*)

Sl No.	Materials	Weight KN/m^3	Angle of Friction, Degrees
(1)	(2)	(3)	(4)
	Bone	18.65	–
	Borax	17.15	–
	Calcite	26.50	–
	Camphor	9.70	–
	Carbon disulphide	12.75	–
	Casein	13.25	–
	Caustic soda	13.85	–
	Creosole	10.50	–
	Dicalcium phosphate	6.65	–
	Disodium phosphate	3.90 to 4.80	30 to 45
	Iodine	48.55	–
	Oils in bottle or barrels	5.70 to 8.90	–
	Oil, linsee:		
	In barrels	5.70	–
	In drums	7.05	–
	Oil, turpentine	8.50	–
	Paints	9.40	–
	Paraffin wax	7.85 to 9.40	–
	Petroleum	9.90	–
	Phosphorus	17.85	–
	Plastics and polymers:		
	Cellulose acetate	12.25 to 13.35	–
	Cellulose nitrate	13.25 to 15.70	–
	Methyl methacrylate (IS 14753) [C-1(15)]	11.57 to 11.77	–
	Phenol formaldehyde	12.55	–
	Expanded Polystyrene (IS 4671) [C-1(15)]	0.15 to 0.35	–
	Extruded polystyrene	0.21	
	Polyvinyl chloride (Perspex)	11.75 to 13.25	–
	Resin bonded sheet	12.85 to 13.55	–
	Urea formaldehyde	13.25 to 13.55	–
	Extruded polystyrene	0.21	
	Polyurethane	0.59 to 0.66	
	Polyethylene (IS 2508) [C-1(15)]	9.81 to 19.6	
	Polyvinyl Butaryl	11	
	Polycarbonate (IS 14443) [C-1(15)]	12	
	Ethylene tetrafluoroethylene	17	
	Polytetrafluoroethylene [IS 14635 (part 2)] [C-1(15)]	22	
	Potash	14.40	–
	Potassium	8.65	–

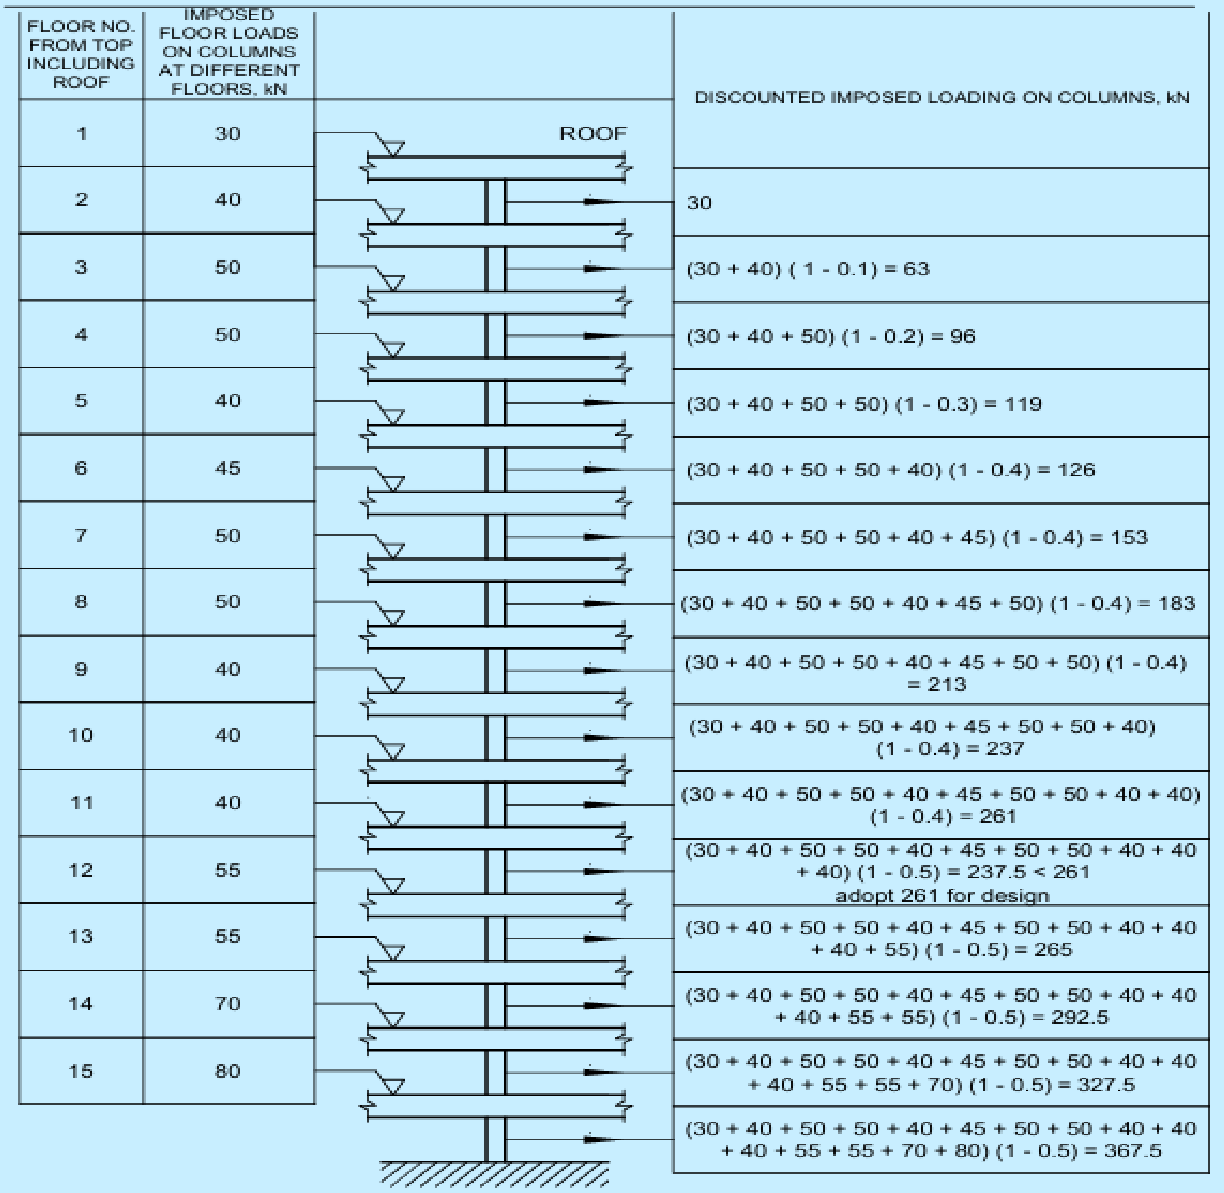
ANNEX B

[*Clause* 3.3.2.1(b)]

ILLUSTRATIVE EXAMPLE SHOWING REDUCTION OF UNIFORMLY DISTRIBUTED IMPOSED FLOOR LOADS IN MULTI-STOREYED BUILDINGS FOR DESIGN OF COLUMNS

B-1 The total imposed loads from different floor levels (including the roof) coming on the central column of a multi-storeyed building (with mixed occupancy) is shown in Fig. 14. Calculate the reduced imposed load for the design of column members at different floor levels using **3.3.2.1**. Floor loads do not exceed 5.0 kN/m^2.

B-1.1 Applying reduction coefficients in accordance with **3.3.2.1**, total reduced floor loads on the column at different levels is indicated along with Fig. 14.



FLOOR NO. FROM TOP INCLUDING ROOF	IMPOSED FLOOR LOADS ON COLUMNS AT DIFFERENT FLOORS, kN	DISCOUNTED IMPOSED LOADING ON COLUMNS, kN
1	30	
2	40	30
3	50	(30 + 40) (1 - 0.1) = 63
4	50	(30 + 40 + 50) (1 - 0.2) = 96
5	40	(30 + 40 + 50 + 50) (1 - 0.3) = 119
6	45	(30 + 40 + 50 + 50 + 40) (1 - 0.4) = 126
7	50	(30 + 40 + 50 + 50 + 40 + 45) (1 - 0.4) = 153

15	80	(30 + 40 + 50 + 50 + 40 + 45 + 50 + 50 + 40 + 40 + 40 + 55 + 55 + 70) (1 - 0.5) = 327.5
		(30 + 40 + 50 + 50 + 40 + 45 + 50 + 50 + 40 + 40 + 40 + 55 + 55 + 70 + 80) (1 - 0.5) = 367.5

FIG. 14 LOADING DETAILS

ANNEX C

(*Clauses* 4.2)

NOTATIONS

C-1 The following notations to be followed unless otherwise specified in relevant clauses under wind loads:

A = Surface area of a structure or part of a structure
A_e = Effective frontal area
A_z = Effective frontal area of the building at height z
b = Breadth of a structure or structural member normal to the wind stream in the horizontal plane
B_s = Background factor
C_d = Drag coefficient
C_f = Force coefficient
C_{fn} = Normal force coefficient
C_{ft} = Transverse force coefficient
C_f' = Frictional drag coefficient
C_p = Pressure coefficient
C_{pe} = External pressure coefficient
C_{pi} = Internal pressure coefficient
C_{fs} = Cross-wind force spectrum coefficient
$C_{f,z}$ = Drag force coefficient of the building corresponding to the area A_z
C = Coefficient, which depends on θ_s, used in the evaluation of k_3 factor
d = Depth of a structure or structural member parallel to wind stream in the horizontal plane
d_w = Wake width
D = Diameter of cylinder or sphere
E = Wind energy factor
F_z = Along wind load on the building/structure at any height z
F = Force normal to the surface
f_a = First mode natural frequency of the building/structure in along wind direction, in Hz
f_c = First mode natural frequency of the building/structure in across wind direction, in Hz
f_s = Vortex shedding frequency
F_n = Normal force
F_t = Transverse force
F' = Frictional force
G = Gust factor
g_R = Peak factor for resonant response
g_v = Peak factor for upwind velocity fluctuations
h = Height of structure above mean ground level
h_x = Height of development of a velocity profile at a distance x down wind from a change in terrain category
H_s = Height factor for resonant response

H = Height above mean ground level on the topography feature

I = Turbulence intensity

$I_{h,i}$ = Turbulence intensity at height h in terrain category i

$I_{z,i}$ = Turbulence intensity at height z in terrain category i

IF = Interference factor

k = Mode shape power exponent

k_1, k_2, k_3, k_4 = Wind speed modification factors

$\overline{k}_{2,i}$ = Hourly mean wind speed factor

K = Force coefficient multiplication factor for individual members of finite length

K_a = Area averaging factor

K_c = Combination factor

K_d = Wind directionality factor

l = Length of the member or larger horizontal dimension of a building

L = Actual length of upwind slope

L_e = Effective length of upwind slope

L_h = Integral turbulence length scale at the height, h

m_0 = Average mass per unit height of the structure

M_a = Design peak along wind base bending moment

M_c = Design peak across wind base bending moment

N = Effective reduced frequency

p_d = Design wind pressure

p_z = Wind pressure at height z

$\overline{P}_d$ = Design hourly mean wind pressure corresponding to $\overline{V}_{z,d}$

p_e = External pressure

p_i = Internal pressure

r = Roughness factor which is twice the longitudinal turbulence intensity at height h, $I_{h\,i}$

R_e = Reynolds number

s = Level on a building/structure for the evaluation of along wind load effects

s_0 = Factor, which depends on H and X, used for the evaluation of k_3 factor

S_t = Strouhal number

S = Size reduction factor

V_b = Regional basic wind speed

V_z = Design wind speed at height z

$\overline{V}_d$ = Design hourly mean wind speed

$\overline{V}_{z,d}$ = Design hourly mean wind speed at height z

$\overline{V}_{z,H}$ = Hourly mean wind speed at height z

w = Lesser horizontal dimension of a building, or a structural member

w' = Bay width in multi-bay building

$\hat{\ddot{x}}$ = Peak acceleration at the top of the building/structure in along wind direction, in m/s^2;

x = Distance down wind from a change in terrain category

X = Distance from the summit or crest of topography feature relative to the effective length, L_e

$\hat{y}$ = Peak acceleration at the top of the building/structure in across wind direction

z = Height or distance above the ground

$z_{0,i}$ = Aerodynamic roughness height for i^{th} terrain

Z = Effective height of the topography feature

α = Inclination of the roof to the horizontal

β = Damping coefficient of the building/structure

η = Shielding factor

ϕ = Factor to account for the second order turbulence intensity

Φ = Solidity ratio

Φ_e = Effective solidity ratio

ε = Average height of the surface roughness

θ_s = Upwind slope of the topography feature in the wind direction

θ = Wind angle from a given axis

ANNEX E

[*Clause* 4.4.3.2.4(b)(2)]

CHANGES IN TERRAIN CATEGORIES

E-1 LOW TO HIGH TERRAIN CATEGORY NUMBER

In cases of transition from a low terrain category number (corresponding to a low terrain roughness) to a higher terrain category number (corresponding to a rougher terrain), the velocity profile over the rougher terrain shall be determined as follows:

a) Below height h_x, the velocities shall be determined in relation to the rougher terrain; and

b) Above height h_x, the velocities shall be determined in relation to the less rough (more distant) terrain.

E-2 HIGH TO LOW TERRAIN CATEGORY NUMBER

In cases of transition from a more rough to a less rough terrain, the velocity profile shall be determined as follows:

a) Above height h_x, the velocities shall be determined in accordance with the rougher (more distant) terrain; and

b) Below height h_x, the velocity shall be taken as the lesser of the following:

   1) That determined in accordance with the less rough terrain; and

   2) The velocity at height h_x as determined in relation to the rougher terrain.

NOTE — Examples of determination of velocity profiles in the vicinity of a change in terrain category are shown in Fig. 15(A) and Fig. 15(B).

E-3 MORE THAN ONE CATEGORY

Terrain changes involving more than one category shall be treated in similar way to that described in **E-1** and **E-2**.

NOTE — Examples involving three terrain categories are shown in Fig. 15(B).

ANNEX F

(*Clause* 4.4.3.3)

EFFECT OF A CLIFF OR ESCARPMENT ON EQUIVALENT HEIGHT ABOVE GROUND (k_3 FACTOR)

F-1 The influence of the topographic feature is considered to extend 1.5 L_e upwind and 2.5 L_e downwind of the summit of crest of the feature where Le is the effective horizontal length of the hill depending on slope as indicated below (*see* Fig. 16):

Slope	L_e
$3° < \theta_s \leq 17°$	L
$\theta_s > 17°$	$Z / 0.3$

where

L = actual length of the upwind slope in the wind direction,

Z = effective height of the topography feature and

θ_s = upwind slope in the wind direction.

In case, the zone in downwind side of the crest of the feature is relatively flat ($\theta_s < 3°$) for a distance exceeding L_e, then the feature should be treated as an escarpment. Otherwise, the feature should be treated as a hill or ridge. Examples of typical features are given in Fig. 16.

NOTES

1 No difference is made, in evaluating k_3 between a three dimensional hill and two dimensional ridge.

2 In undulating terrain, it is often not possible to decide whether the local topography to the site is significant in terms of wind flow. In such cases, the average value of the terrain upwind of the site for a distance of 5 km should be taken as the base level from wind to assess the height, Z and the upwind slope θ, of the feature.

F-2 TOPOGRAPHY FACTOR, k_3

The topography factor k_3 is given by the following:

$$k_3 = 1 + C\, s_0$$

where C has the following values:

Slope	*C*
$3° < \theta_s \leq 17°$	$1.2\,(Z/L)$
$\theta_s > 17°$	0.36

and s_0 is a factor derived in accordance with **F-2.1** appropriate to the height, H above mean ground level and the distance, X, from the summit or crest relative to the effective length, L_e.

F-2.1 The factor, s_0 should be determined from:

a) Fig. 17 for cliffs and escarpments; and

b) Fig.18 for ridges and hills.

NOTE — Where the downwind slope of a hill or ridge is more than 3°, there will be large regions of reduced accelerations or even shelter and it is not possible to give general design rules to cater for these circumstances. Values of s_0 from Fig. 18 may be used as upper bound values.

ANNEX G

[*Clauses* 4.5.4.2.2, 4.5.4.3.2(c) *and* 4.5.4.3.3]

WIND FORCE ON CIRCULAR SECTIONS

G-1 The wind force on any object is given by:

$$F = C_f A_e p_d$$

where

C_f = force coefficient;
A_e = effective area of the object normal to the wind direction; and
p_d = design pressure of the wind.

For most shapes, the force coefficient remains approximately constant over the whole range of wind speeds likely to be encountered. However, for objects of circular cross section, it varies considerably.

For a circular section, the force coefficient depends on the way in which the wind flows around it and is dependent upon the velocity and kinematic viscosity of the wind and diameter of the section. The force coefficient is usually quoted against a non-dimensional parameter, called the Reynolds number, which takes into account of the velocity and viscosity of the flowing medium (in this case the wind) and the member diameter.

$$\text{Reynolds number, } R_e = \frac{D\overline{V}_d}{\nu}$$

where

D = diameter of the member;
$\overline{V}_d$ = design hourly mean wind speed; and
ν = kinematic viscosity of the air which is 1.46×10^{-5} m^2/s at 15° and standard atmospheric pressure.

Since in most natural environments likely to be found in India, the kinematic viscosity of the air is fairly constant, it is convenient to use $D\overline{V}_d$ as the parameter instead of Reynolds number and this has been done in this Section.

The dependence of a circular section's force coefficient on Reynolds number is due to the change in the wake developed behind the body.

At a low Reynolds number, the wake is as shown in Fig. 19 and the force coefficient is typically 1.2. As Reynolds number is increased, the wake gradually changes to that shown in Fig. 20, that is, the wake width d_w decreases and the separation point, denoted as s_p, moves from front to the back of the body.

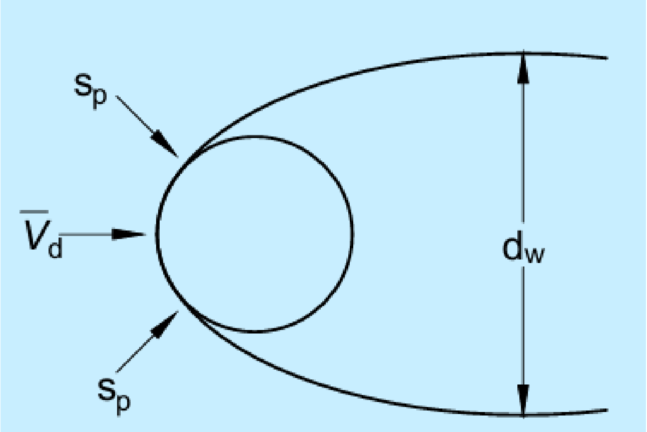

FIG. 19 WAKE IN SUB-CRITICAL FLOW

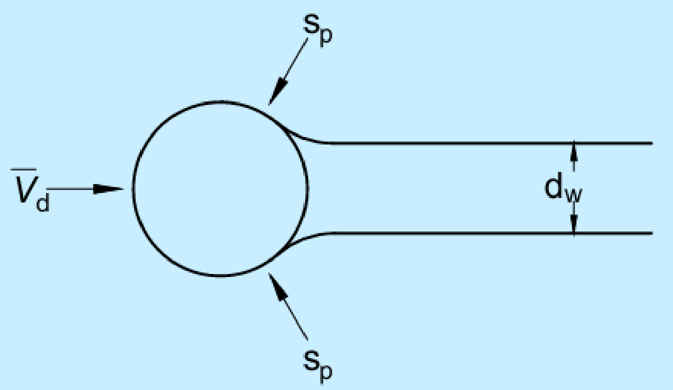

FIG. 20 WAKE IN SUPER-CRITICAL FLOW

As a result, the force coefficient shows a rapid drop at a critical value of Reynolds number followed by a gradual rise as Reynolds number is increased still further.

The variation of C_f with parameter $D\overline{V}_d$ is shown in Fig. 5 for infinitely long circular cylinders having various values of relative surface roughness (ε/D) when subjected to wind having an intensity and scale of turbulence typical of built-up urban areas. The curve for a smooth cylinder (ε/D) = 1×10^{-5} in a steady air stream, as found in a low-turbulence wind tunnel, is also shown for comparison.

It can be seen that the main effect of free-stream turbulence is to decrease the critical value of the parameter $D\overline{V}_d$. For subcritical flows, turbulence can produce a considerable reduction in C_f below the steady air-stream values. For supercritical flows, this effect becomes significantly smaller.

If the surface of the cylinder is deliberately roughened, such as by incorporating flutes, riveted construction, etc, then the data given in Fig. 5 for appropriate value of $\varepsilon/D > 0$ shall be used.

NOTE — In case of uncertainty regarding the value of ε to be used for small roughness, ε/D shall be taken as 0.001.

ANNEX H

(*Foreword* *and clause* 7.3.2)

CHARACTERISTIC GROUND SNOW LOAD

H-1 This annex presents the characteristic ground snow load computation procedure for the union territory of Jammu and Kashmir, union territory of Ladakh, Himachal Pradesh, Uttarakhand and Sikkim which is the result of scientific work carried out by Defence Geoinformatics Research Establishment (DGRE), Chandigarh under Defence Research and Development Organization (DRDO).

H-2 The characteristic value of the ground snow load at any site is defined with a 3.4 percent annual exceedance probability or, equivalently, with a mean recurrence interval, MRI = 30 years. The site altitude is the altitude at which the structure is or will be located, measured from mean sea level. The procedure shall be used for the computation of characteristic ground snow load on sites with an altitude higher than 1000 m and lower than 4000 m from mean sea level.

H-3 The characteristic ground snow load, s_0 (kPa) to be used for any site in the union territory of Jammu and Kashmir, union territory of Ladakh, Himachal Pradesh, Uttarakhand should be obtained from the zone map shown in Fig. 21 and equation given below:

$$s_0 = 1.624 \times [Z - 0.5] \times \left[1 + \left(\frac{A}{2677}\right)^2\right] \text{ kPa}$$

where

s_0 = characteristic ground snow load (kPa);

Z = zone number (for example 1, 2, 3, 4 or 5) obtained from the zone; and

A = map in Fig. 21.

H-4 The characteristic ground snow load s_0 (kPa) to be used for any site in Sikkim should be directly obtained from the characteristic ground snow load map shown in Fig. 22.

H-5 The ground snow loads for any mean recurrence interval of n years, different to that for the characteristic snow load, s_0, (which by definition is based on annual probability of exceedance of 0.034 that is MRI = 30 years) shall be calculated by the equation given below:

$$s_n = s_0 \left\{ \frac{1 - C_{\mathrm{v}} \frac{\sqrt{6}}{\pi} \left[ln\left(-ln(1 - P_{\mathrm{n}})\right) + 0.577\,22 \right]}{(1 + 2.188\,7 C_{\mathrm{v}})} \right\}$$

where

s_0 = characteristic snow load on the ground with MRI = 30 years

s_n = characteristic snow load on the ground with MRI = 30 years

P_{n} = annual probability of exceedance (equivalent to $1/n$, where n is the corresponding recurrence interval in years)

C_{v} = coefficient of variation of annual maximum snow load.

H-5.1 The coefficient of variation of maximum snow load at different snow-meteorological observatories of DGRE located in union territory of J and K, union territory of Ladakh, HP and UK ranges between 0.35 to 0.65. For application of above equation, a constant value of $C_{\mathrm{v}} = 0.5$ is recommended for all the zones to calculate snow loads on the ground for other probability of exceedance (for example, MRI of 50 years for structures where a higher risk of exceedance is deemed acceptable). The above equation is shown graphically in Fig. 23.

NOTES

1 The characteristic ground snow load *versus* altitude relation as given above in equation and Fig. 21 is determined based on the snow depth observations at more than 70 field observatories of DGRE located in different parts of union territory of Jammu and Kashmir, union territory of Ladakh and states of Himachal Pradesh and Uttarakhand as well as High Asia Refined analysis (HAR10) dataset (HAR, Maussion et al., 2014).

2 Since adequate snow depth measurements are not available for Sikkim region, hence the characteristic ground snow load map for Sikkim given in Fig. 22 is generated based solely on high Asia refined analysis (HAR10) dataset (HAR, Maussion et al., 2014).

3 Annex H does not apply for sites at altitudes above 4000 m. For altitudes greater than 4000 m specialist advice should be sought from DGRE on the characteristic ground snow loads likely to occur at the site.

4 Unusual local effects have not been accounted for in the analysis undertaken to produce the characteristic ground snow load map given in Annex H. These include local shelter from the wind, which can result in increased local snow loads and local configurations in mountainous areas, which may funnel the snow and give increased local loading. Annex H is also not applicable for sites with permanent snow/ice cover throughout the year. If the designer suspects that there are unusual local conditions that need to be taken into account, DGRE may be consulted.

5 In special cases where more refined data is needed, the characteristic value of snow load on the ground (s_0) may be refined using an appropriate statistical analysis of long term records taken in a well sheltered area near the site.

6 Ground characteristics snow load at any place depends on the critical combination of maximum depth of undisturbed aggregate cumulative snowfall and its density. In due course the characteristics snow load for states of Arunachal Pradesh will be included based on studies. Till such time the users of this section are advised to consult DGRE for the specific information relating to the state of Arunachal Pradesh.

ANNEX J

(*Clauses* 7.4.2.4 *and* 7.4.3)

SHAPE COEFFICIENTS FOR MULTILEVEL ROOFS

J-1 A more comprehensive formula for the shape coefficient for multilevel roofs than that given in **7.4.2** is as follows:

$$\mu_w = 1 + \frac{1}{h}\left(m_1 l_1 + m_2 l_2\right)\left(l_2 - 2h\right)$$

$$\mu_1 = 0.8$$

$$l_3 = 2h$$

$$(h \text{ and } l \text{ in m})$$

Restriction:

$$\mu_w \leq \frac{kh}{S_o}$$

where

S_0 = kilopascals (kilonewtons per square metre)

k = newtons per cubic metre

l_3 = $\leq 15\ m$

Values of $m_1(m_2)$ for the higher (lower) root depend on its profile and are taken as equal to:

0.5 for plane roofs with slopes $\beta \leq 20°$ and vaulted roofs with $\frac{f}{l} \leq \frac{1}{18}$

0.3 for plane roofs with slopes $\beta \leq 20°$ and vaulted roofs with $\frac{f}{l} \leq \frac{1}{18}$

The coefficient m_1 and m_2 may be adjusted to take into account conditions for transfer of snow on the roof surface (that is wind, temperature, etc).

NOTE — The other condition of loading shall also be tried.

ANNEX K

(*Clause* 8.7)

VIBRATIONS IN BUILDINGS

K-1 GENERAL

In order to design the buildings safe against vibrations, it is necessary to identify the source and nature of vibration. Vibrations may be included in the buildings due to various actions, such as:

a) human induced vibrations, for example, the walking or running or a single person or a number of persons or dancing or motions in stadia or concert halls;

b) machine induced vibrations;

c) wind induced vibrations;

d) blast induced vibrations;

e) traffic load, for example, due to rail, fork-lift, trucks, cars, or heavy vehicles;

f) airborne vibrations;

g) crane operations; and

h) other dynamic actions such as wave loads or earthquake actions.

The dynamic response of buildings for the above mentioned causes of vibration of buildings may have to be evaluated by adopting standard mathematical models and procedures.

The severity or otherwise of these actions have to be assessed in terms of the limits set for dynamic response (frequencies and amplitude of motion) of the buildings related to (a) human comfort, (b) serviceability requirements such as deflections and drifts and separation distances to avoid damage due to pounding and (c) limits set on the frequencies and amplitude of motion for machines and other installations.

In order to verify that the set limits are not exceeded, the actions may be modelled in terms of force-time histories for which the structural responses may be determined as time histories of displacements or accelerations by using appropriate analytical/numerical methods.

K-2 SERVICEABILITY LIMIT STATE VERIFICATION OF STRUCTURE SUSCEPTIBLE TO VIBRATIONS

K-2.1 While giving guidance for serviceability limit state verification of structure susceptible to vibrations, here it is proposed to deal with the treatment of the action side, the determination of the structural response and the limits to be considered for the structural response to ensure that vibrations are not harmful or do not lead to discomfort.

K-2.2 Source of Vibrations

Vibrations may be included by the following sources:

a) by the movement of persons as in pedestrian bridges, floors where people walk, floors meant for sport or dancing activities and floors with fixed seating and spectator galleries;

b) by working of machines as in machine foundations and supports, vibrations transmitted through the ground and pile driving operations;

c) by wind blowing on buildings, towers, chimneys and masts, guyed masts, pylons, bridges, cantilevered roofs, airborne vibrations;

d) induced by traffic on rail or road bridges and car park structures and exhibition halls; and

e) by earthquakes.

K-2.3 Modelling of Actions and Structures

For serviceability limit states, the modelling of these actions and of the structure depends on how the serviceability limits are formulated. The serviceability limit states may refer to:

a) human comfort;

b) limits for the proper functioning of machines and other installations; and

c) maximum deformation limits to avoid damage or pounding.

In order to verify that these limits are not exceeded, the actions may be modeled in terms of force-time histories, for which the structural responses may be determined as time histories of displacements or accelerations by using appropriate analytical/numerical methods. Where the structural response may significantly influence the force-time histories to be applied, these interactions have to be considered either in modeling a combined load-structure vibration system or by appropriate modifications of the force time histories. In addition to the levels of vibration for which presently limits have been specified, the possible deformations of structural members and systems using different clauses in the relevant codes have to be evaluated by adopting standard mathematical models and procedures.

K-2.4 Force-Time Histories

The force-time histories used in the dynamic analysis should adequately represent the relevant loading situations for which the serviceability limits are to be verified. The force-time histories may model:

a) human induced vibrations, for example the walking or running of a single person or a number of persons or dancing or motions in stadia or concert halls;

b) machine induced vibrations, for example by force vectors due to mass eccentricities and frequencies, that may be variable with time;

c) wind induced vibrations;

d) blast induced vibrations;

e) traffic load, for example rail, fork-lift, trucks, cars, or heavy vehicles;

f) airborne vibrations;

g) crane operations; and

h) other dynamic actions such as wave loads or earthquake actions.

ANNEX L

(*Foreword and clause* 8.8)

BLAST LOAD

L-1 BLAST LOAD

L-1.1 This annex prescribes the minimum criteria for analysis and design of new structures for blast effects of above-ground explosions of high-explosives under three different detonation scenarios: surface burst, free-air burst and air burst. The primary objective of this annex is to minimize human casualties and safeguard assets due to above ground explosions. The performance expectation of a structure designed as per the provisions of this annex would depend on the type of protection category selected for that structure and the blast loading determined through threat assessment.

L-1.2 This annex shall be used in conjunction with other applicable standards for analysis and design of structures. This annex does not supersede or replace other design standards. This annex shall be applicable if design against malevolent or accidental blast loading is determined to be a credible threat to a structure.

L-1.3 The owner of a structure is the competent authority who can determine the necessity of blast-resistant design. In the scenario of accidental and malevolent blast event which may pose public health and safety issue, competent authorities other than the owner of building that govern or regulate the construction, operation and maintenance of the structural facility, can specify the requirement of blast-resistant design.

L-1.4 The provisions of this annex do not address the following:

a) Estimation of structural loads due to nuclear detonations, pressure vessel explosions, dust and vapour cloud explosions;

b) Effects of cased explosives and shaped charges;

c) Threats emanating from fragmentation, induced fire or thermal effects, biological or chemical radiations, electromagnetic pulse (EMP) and deflagration events; and

d) Detonations in contact with structural elements.

L-2 TERMINOLOGY

For the purpose of this annex, the following definitions shall apply.

L-2.1 Arrival Time — Time taken by the shock after the explosion to reach the location of interest.

L-2.2 Charge Mass — Mass of the explosive material responsible for generating blast effects.

L-2.3 Clearance Time — Time in which the reflected pressure decays down to the sum of the side on overpressure and the dynamic pressure.

L-2.4 Close-in Detonation — Detonation at a scaled distance (Z) below which the resulting blast pressure distribution is non-uniform over the reflecting surface of the element being considered. It corresponds to a value of Z less than 1.2 m/kg1/3.

L-2.5 Decay Parameter — The coefficient of the negative power of exponent e governing the fall of pressure with time in the pressure-time curves.

L-2.6 Detonation — Fast and sudden release of huge amount of energy through a stable chemical reaction in which reaction front propagates into unreacted substance at supersonic speed resulting in formation of shock waves.

L-2.7 Drag Force — Force on a structure or structural element due to the dynamic pressure of the blast wave. On any structural element, the drag force equals dynamic pressure multiplied by the drag coefficient and the area of the element.

L-2.8 Ductility Ratio — Ratio of the maximum deflection to the deflection corresponding to the elastic limit.

L-2.9 Dynamic Increase Factor (DIF) — A factor applied to material strength to account for high strain rate loading effects.

L-2.10 Dynamic Pressure — The pressure due to air mass movement behind the shock front.

L-2.11 Exponential Blast Pressure History — The variation of blast pressure with time at a point represented through an exponential decaying function, which considers positive and negative phase of blast overpressures.

L-2.12 Far-Field Detonation — Detonation at a scaled distance (Z) above which the resulting blast pressure distribution is uniform over the reflecting surface of element being considered. It corresponds to a value of Z greater than 1.2 $m/kg^{1/3}$.

L-2.13 High-Explosives — Chemical explosive that undergoes detonation to produce shock waves with high pressure and short duration.

L-2.14 Impulse — The integral of the pressure-time curve per unit projected area due to explosion (*see* specific impulse).

L-2.15 Mach Number — The ratio of the speed of the shock front propagation to the speed of sound in standard atmosphere at sea level.

L-2.16 Negative Phase — The duration of reflected overpressure when it is below the ambient atmospheric pressure.

L-2.17 Overpressure — The rise in pressure above atmospheric pressure due to the shock wave from an air blast.

L-2.18 Positive Phase —The duration of overpressure when it is above the ambient atmospheric pressure.

L-2.19 Protection Category — Category assigned to different structures that correlates its importance to the performance goals through qualitative estimate of damage.

L-2.20 Reflected Overpressure —The overpressure resulting due to reflection of a shock wave front striking any surface. If the shock front is parallel to the surface, the reflection is normal.

L-2.21 Regular Shaped Structure — A structure that does not have any spatial geometric irregularity.

L-2.22 Scaled Distance — The distance between the centre of explosion to the point of interest divided by the cube root of the charge mass expressed in equivalent TNT. The unit for scaled distance is $m/kg^{1/3}$.

L-2.23 Shape Function — The displaced shape of the component as a function of its length normalized to the maximum deflection.

L-2.24 Shock Wave Front — The discontinuity between the blast wave and the surrounding atmosphere. It propagates away from the point of explosion in all directions at a speed greater than the speed of sound in the undisturbed atmosphere.

L-2.25 Side-on (Incident) Overpressure — Overpressure if it is not reflected by any surface.

L-2.26 Simplified Overpressure History — A triangular representation of the overpressure history obtained by equating the impulse and the peak overpressure of the exponential representation of the overpressure history.

L-2.27 Specific Impulse — The area under the pressure-time curve due to explosion. This is often referred to as impulse (*see* **L-2.13**).

L-2.28 Standoff Distance — The shortest distance between the centre of detonation and the point of interest at which the effects of explosion need to be considered.

L-2.29 Support Rotation — The angle formed by a flexural member in its deflected shape with respect to the chord adjoining the two support ends (*see* Fig. 45).

L-2.30 Transit Time — Time required for the shock front to travel across the structure or its element under consideration.

L-3 SYMBOLS

For the purpose of this annex, the following notations shall apply.

b	Decay parameter/coefficient
C_d	Drag coefficient
C_r	Velocity of sound in air
$C_{r\alpha}$	Reflection coefficient
E	Modulus of elasticity of material
H	Height of the structure
I	Moment of inertia of member
i_e	Equivalent specific impulse of a uniformly distributed load
i_{ro}	Peak reflected specific impulse
j	Number of concentrated load points
K_L	Load factor
K_{LM}	Load mass factor
K_M	Mass factor
k_E	Effective stiffness of equivalent single spring-mass system
L	Length of structure in the direction of motion of blast wave (*see* Fig. 39)
M	Charge mass/weight
M_p	Plastic moment of section
M_{pm}	M_p at mid-span
M_{ps}	M_p at support
M_{pfa}	Total positive ultimate moment capacity along mid-span section parallel to short edge
M_{pfb}	Total positive ultimate moment capacity along mid-span section parallel to long edge

m	Distributed mass intensity per unit length
n	Number of concentrated masses
p_a	Ambient atmospheric pressure
P_r	Concentrated dynamic force at point *r*
p_ro	Peak reflected overpressure
p_s	Side-on overpressure
p_so	Peak side-on overpressure
P_t	Total dynamic load (at any instant of time)
$p(x)$	Intensity of distributed dynamic load per unit length
p_o1	Peak reflected overpressure on a surface including the effects of clearing
p_o2	Intercept of the reflected overpressure history on the y-axis corresponding to the clearing phase
q	Dynamic pressure
q_o	Peak dynamic pressure
R	Standoff distance
R_m	Peak resistance of a structural member against a given load distribution
S	W or H whichever is less
T	Elastic time-period of structural member
t_c	Clearance time
t_d	Duration of the equivalent triangular pulse
t_m	Time to the peak displacement of an SDOF system
t_o	Time for positive phase of side-on overpressure
t_t	Transit time
t_d1	Time at which clearing starts on a finite reflecting surface (*see* Fig. 47B)
t_d2	Total time duration of blast loading on a finite reflecting surface (*see* Fig. 47B)
U	Shock front velocity
u	Peak particle velocity
V_A	Total dynamic reaction along a short edge
V_B	Total dynamic reaction along a long edge
y_E	Displacement corresponding to the elastic limit of an equivalent bilinear representation of idealised resistance-deflection curve
y_el	Displacement corresponding to the first onset of yielding (elastic limit) of the idealized resistance-deflection curve of a structural member
y_m	Maximum deflection/deformation permitted in the design of the structure
y_o	Peak static displacement of an SDOF system without inertial effects
W	Span or width of structure across the direction of shock wave propagation
Z	Scaled distance

μ	Ductility ratio = $\frac{y_m}{y_E}$
φ_r	Deflection at point *r* of an assumed deflected shape for concentrated loads
$\varphi_{(x)}$	Deflection at point *x* of an assumed deflected shape for distributed loads
$\varphi_{(x,y)}$	Deflected shape function of blast-loaded component

L-4 GENERAL PRINCIPLES

L-4.1 Blast Resistant Design Attributes

The design process of a building against blast should start with planning of building layout and arrangements. The distance between the explosive and the building shall be maximized through a combination of site-access controls, landforms, anti-ram structures, street and site landscaping and perimeter walls. The building should preferably have short-face oriented towards blast source. Also, it shall be located uphill and placed upstream of wind direction and away from congestion. The structures and their contents that need protection against an explosion event should be decided and all possible scenarios need to be considered which can cause damage or occupant injuries. The overall design of a structure shall aim to incorporate following attributes in the overall planning and design of a facility against explosion threats:

a) *Security* — Discourage potential terrorist attacks on a structure through visible security personnel deployment and defences to reduce chance of such attacks;

b) *Deception* — Disguise the critical area or content of structure so that the focus of the attack is misdirected. Such attacks, even if successfully completed, may not deliver intended impact and realize its goals;

c) *Shielding* — Shield the target structure through physical barriers, including but not limited to blast walls, bollards, anti-ram elements, vehicle and pedestrian entry controls and landforms. The objective of shielding is to increase the standoff distance between the charge and the target structure and components; and

d) *Design* — The attack must be blunted through appropriate design and detailing of the structure to absorb the energy of the attack and safeguard valuable assets.

L-4.2 Blast Source

L-4.2.1 *Charge Shape*

The provisions of this annex shall be applicable for:

a) explosives of spherical shape; and

b) non-spherical charges if the detonation effects are considered at scaled distances greater than 3 m/kg$^{1/3}$.

In case of non-spherical charges at scaled distances smaller than 3 m/kg$^{1/3}$, the provisions of **L-8.3.3** shall be applicable with explicit modelling of the detonation process.

L-4.2.2 *Detonation Scenarios*

The standard addresses three scenarios of unconfined explosions based on the location of the detonation with respect to the point of interest:

a) Spherical (free-air) burst (*see* Fig. 24);

b) Hemispherical (surface) burst (*see* Fig. 25); and

c) Air-burst (*see* Fig. 26).

L-4.2.3 *Standoff Distance*

The standoff distance (*R*) shall be estimated as the distance between the centre of detonation and the point of interest. If the location of interest is not directly in the line of the sight from the centre of detonation, then Fig. 27 shall be referred to estimate the effective standoff distance.

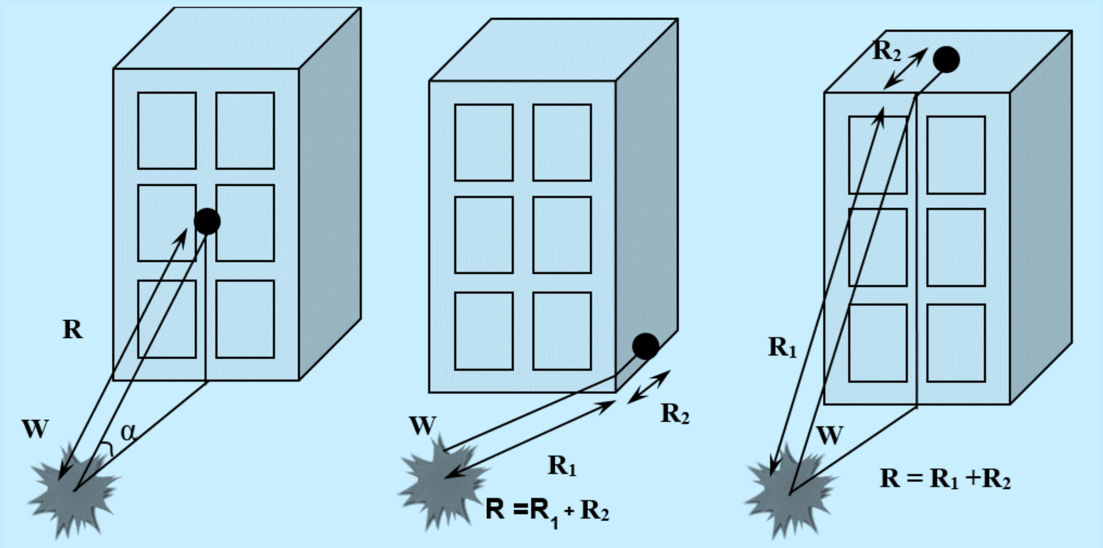

FIG. 27(A) FRONT FACE FIG. 27(B) SIDE FACE FIG. 27(C) TOP FACE

FIG. 27 CALCULATION OF STANDOFF DISTANCES AT DIFFERENCE FACES OF A BUILDING STRUCTURE

L-4.2.4 *Equivalent TNT Charge*

Trinitrotoluene (TNT) shall be used to benchmark all types of explosives. To quantify blast wave parameters (pressure, impulse) from explosives other than TNT, the actual mass of the explosive (M_{EXP}) shall be converted into a TNT-equivalent mass. The TNT equivalent weight (M_{TNT}) of any explosive shall be estimated as:

$$M_{\mathrm{TNT}}=\left(\frac{\Delta E_{\mathrm{EXP}}}{\Delta E_{\mathrm{TNT}}}\right) M_{\mathrm{EXP}}$$

where

ΔE_{EXP} and ΔE_{TNT} are the specific energies of the explosive and the TNT, respectively.

The factors presented in Table 42 shall be utilized to obtain equivalent mass of TNT corresponding to the listed explosives.

NOTE

[*] NA — Data not available.

[Ɨ] Value is estimated.

L-4.2.5 *Cube Root Scaling*

Cube root scaling shall be used to relate blast parameters from different sources and standoff distances. The cube-root scaling shall be valid if the conditions specified in **L-4.2.1** are satisfied.

The blast load parameters can be obtained in scaled form as function of scaled distance, *Z*, as:

$$Z = \frac{R}{M^{1/3}}$$

where

R = standoff distance of the point of interest from the centre of charge mass; and

M = Mass in equivalent TNT.

The unit for scaled distance shall be m/kg$^{1/3}$, for standoff distance in m and charge mass in kg.

L-4.3 Performance Expectations

L-4.3.1 *Categorization of Structures*

Structures shall be categorized based on their importance as per the specification of Table 43.

The categorisation of structures as per Table 43, does not automatically require them to be designed for explosion threats. Only, if the threat assessment carried as per the provisions of **L-5.1** identifies blast loading due to explosion as a potential threat, the categorisation in Table 43 shall be used to define the importance of a structure.

Table 43 Categories of Structures

(*Clause* L-4.3.1)

Sl No. (1)	Importance (2)	Structure Type (3)
i)	Low	Residential buildings with 50 or less occupants
ii)	Medium	a) Residential buildings with more than 50 occupants b) Buildings with large congregation, such as schools, public offices and cinemas c) Industrial buildings with continuous human occupancy
iii)	High	a) Lifeline structures (water, power, communication, transportation, hospital) b) Structures housing essential services that are required for disaster management (for example, emergency relief stores, data centres, governance continuity buildings) c) Financial and commercial establishments of strategic importance

L-4.3.2 *Structural Performance*

A protection category shall be decided by the building owner based on the importance of the building and required performance. The performance goals for each protection category are listed in Table 44.

Table 44 Protection Category and Associated Performance Goals

(*Clause* L-4.3.2)

Sl No. (1)	Protection Category (2)	Performance Goal (3)
i)	1	Minimal damage, resumption after brief halt of operations
ii)	2	Limited damage, operational after repairs and retrofit
iii)	3	Extensive damage, safe replacement, or demolition

Structures of high, medium and low importance shall be provided with protection categories 1, 2 and 3 respectively, as at least a minimum as specified in Table 45.

The facility owner may specify a protection category higher than the minimum protection category specified in Table 45 based on the realistic assessment of threat.

Table 45 Protection Category and Associated Category of Structures

(*Clause* L-4.3.2)

Sl No.	Building Category	Minimum Protection Category
(1)	(2)	(3)
i)	Low	3
ii)	Medium	2
iii)	High	1

The protection categories specified in shall comply with the deformation limits of structural elements provided in **L-8.1.4** when using simplified single degree of freedom (SDOF) and multi degree of freedom (MDOF) methods of analysis as per requirements of **L-8.3.1** and **L-8.3.2** respectively. Accordingly, all elements shall be designed and detailed to provide deformation limits specified for different protection categories.

If advanced methods of analysis are used as per **L-8.3.3**, the response and damage in structure and elements for the performance goals of each protection category mentioned in can be independently established. In such case, deformation limits specified in **L-8.3.1** and **L-8.3.2** need not to be used.

L-5 THREAT ASSESSMENT

L-5.1 Threat Assessment Parameters

A threat assessment shall be carried out to determine all potential sources of detonation.

The threat assessment shall identify two parameters for the purpose of calculation of blast load parameters, namely:

a) charge mass; and

b) standoff distance.

If threat assessment identifies multiple sources of detonation, the effect of blast on the structure shall be assessed considering individual, as well as combinations of all identified detonation threats.

L-5.2 Design Blast (Reference Explosion)

L-5.2.1 *Design TNT Equivalence*

If the threat scenario results in identification of one of the detonation sources listed in Table 46, then the associated charge mass may be used for determination of equivalent TNT capacity.

L-5.2.2 *Standoff Distance*

The standoff distance (*R*) is site specific and shall be estimated as per the actual geometry and access control of the target structure.

L-6 BLAST LOAD

L-6.1 Blast Wave Propagation

The blast loads for design of structures and components shall be determined from blast pressure history.

Table 46 Detonation Source and the Associated Charge Mass

(*Clause* L-5.2.1 *and* Table 60)

Sl No.	Threat Description		Explosive Capacity (TNT Equivalent)
(1)	(2)	(3)	(4)
i)		Pipe bomb	2.5 kg
ii)		Suitcase	25 kg
iii)		Hatchback	250 kg
iv)		Sedans/SUV	500 kg
v)		Passenger van/small cargo truck	2 000 kg
vi)		Delivery truck	5 000 kg
vii)		Water tanker/diesel truck/gas truck	15 000 kg

The variation of pressure at a fixed location away from the centre of detonation shall be obtained using following assumptions:

a) the shock wave due to explosion moves away from the centre of detonation at a speed, U;

b) when the shock wave reaches a point at the arrival time t_a, the pressure rises instantaneously from the ambient pressure (p_a) to a peak pressure. This peak pressure, p_{so}, is known as side-on overpressure or peak incident overpressure;

c) the time needed for the pressure to reach its peak value is very small and for design purposes it is assumed to be zero;

d) the overpressure decreases exponentially from its peak value to the ambient pressure over the positive phase duration (t_o). After the positive phase of the pressure-time profile, the pressure becomes smaller than the ambient value (referred to as negative pressure) and finally returns to the ambient pressure, p_a;

e) the movement of air caused by the shock wave induces dynamic pressure, in addition to blast pressure. Air dynamic pressure q_o and peak particle velocity u shall be obtained using peak incident pressure, p_{so} (*see* Fig. 32 and Fig. 33); and

f) shock wave upon reflection from a rigid surface would apply reflected overpressure, p_r, to the reflecting surface. The variation of reflected overpressure with time for normal reflection follows the same trend as the incident overpressure but characterized by significantly higher peak overpressure.

L-6.2 Decay of Blast Overpressure with Time

The blast overpressure is assumed to vary with time, t according to the following exponential relationship (*see* Fig. 28):

$$p_s(t) = p_o\left(1-\frac{t}{t_o}\right)e^{-b(t/t_o)}$$

where

p_o = peak blast overpressure, which is interpreted as the peak incident and reflected overpressures for the incident and the reflected blast wave, respectively; and

b = decay coefficient; and t_o is the positive phase duration. Special literature is to be referred for the calculation of the blast wave decay parameter, b.

L-6.3 Blast Overpressure History Parameters

The maximum values of the positive side-on overpressure p_{so}, incident impulse i_s, reflected over pressure p_r, reflected impulse i_r, positive phase duration t_o, shock wave front velocity U and wave length L_w, for varying scaled distances, are to be obtained for a spherical TNT explosion in free air and a hemispherical TNT explosion on the surface using Fig. 30 and Fig. 31, respectively. Further, air dynamic pressure q_o and peak particle velocity u, are to be obtained using Fig. 32 and Fig. 33, respectively.

FIG. 28 INCIDENT AND REFLECTED BLAST PRESSURE HISTORY

L-6.4 Oblique Reflection of Blast Wave

The clauses of this section are applicable to determine the peak reflected overpressure for scenarios where the angle between the wave front and the interacting surface is α (≤ 90°) as shown in Fig. 29. In such case, the peak reflected overpressure (p_{ro}) is to be determined as multiplication of peak incident overpressure (p_{so}) with a reflection coefficient ($C_{r\alpha}$). The reflection coefficient at any angle is to be determined from Fig. 34 for given incident overpressure.

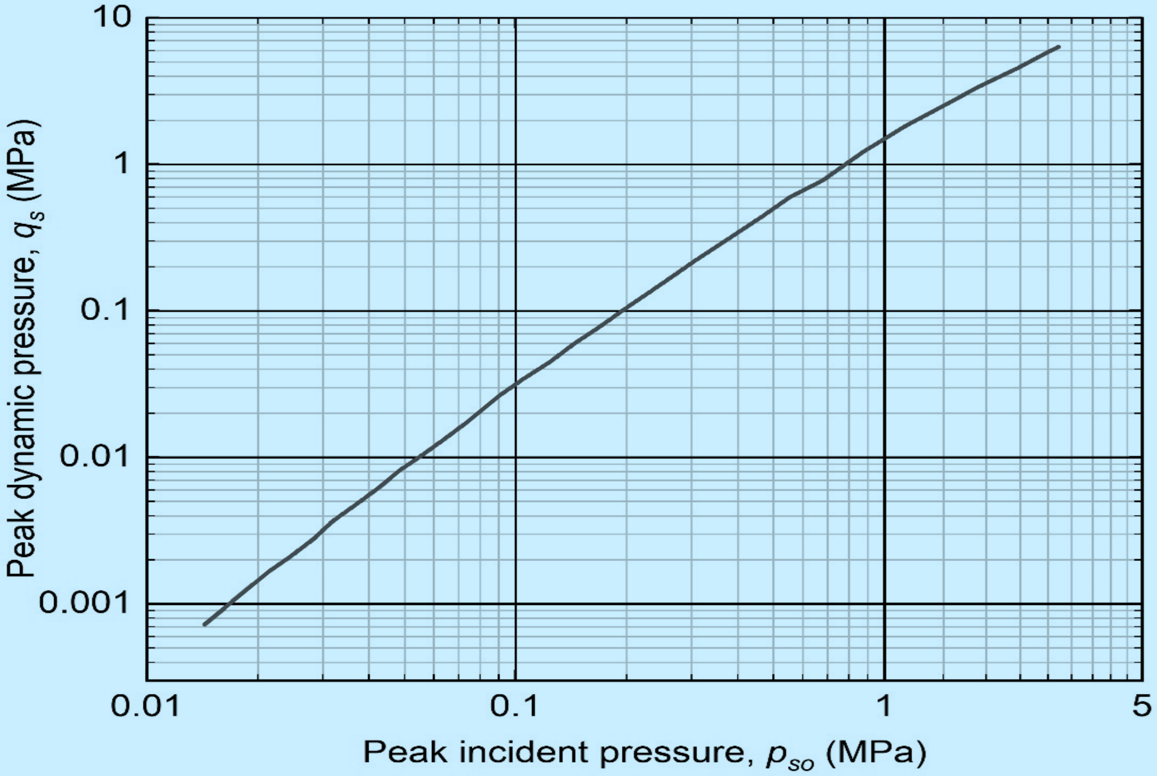

FIG. 32 PEAK DYNAMIC PRESSURE AND PEAK PARTICLE VELOCITY BEHIND A SHOCK FRONT

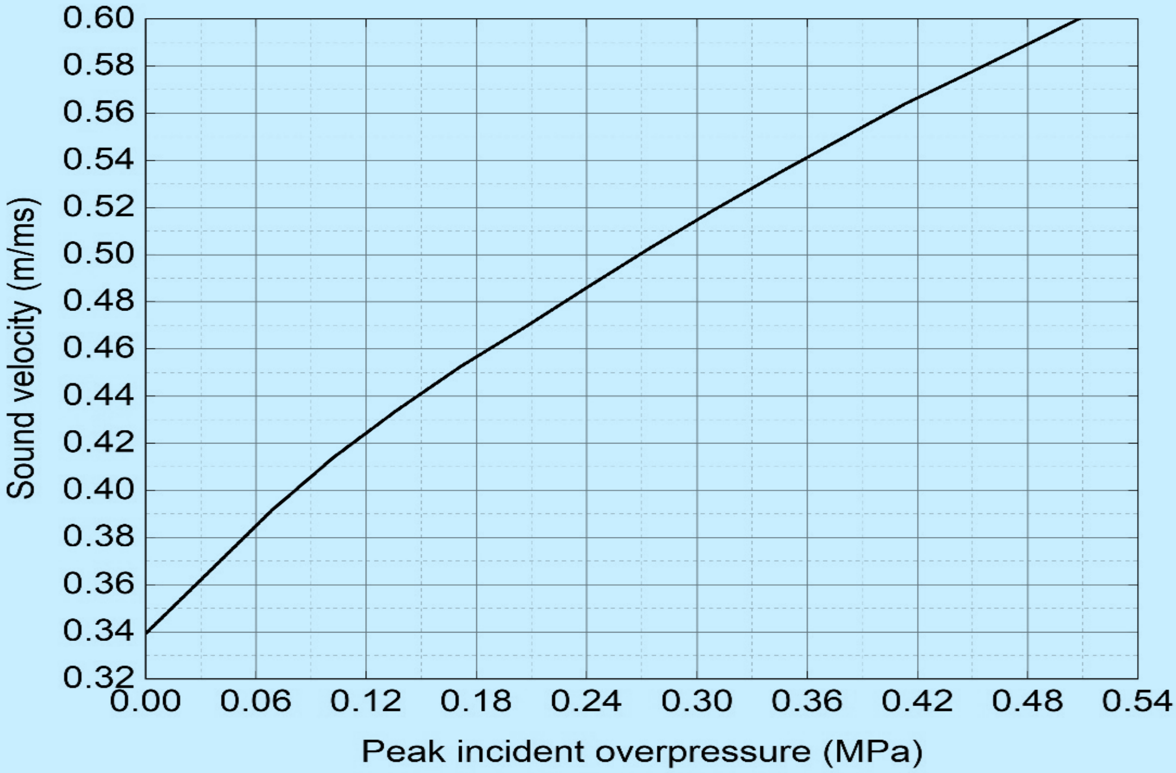

FIG. 33 SOUND VELOCITY IN THE REFLECTED OVERPRESSURE REGION

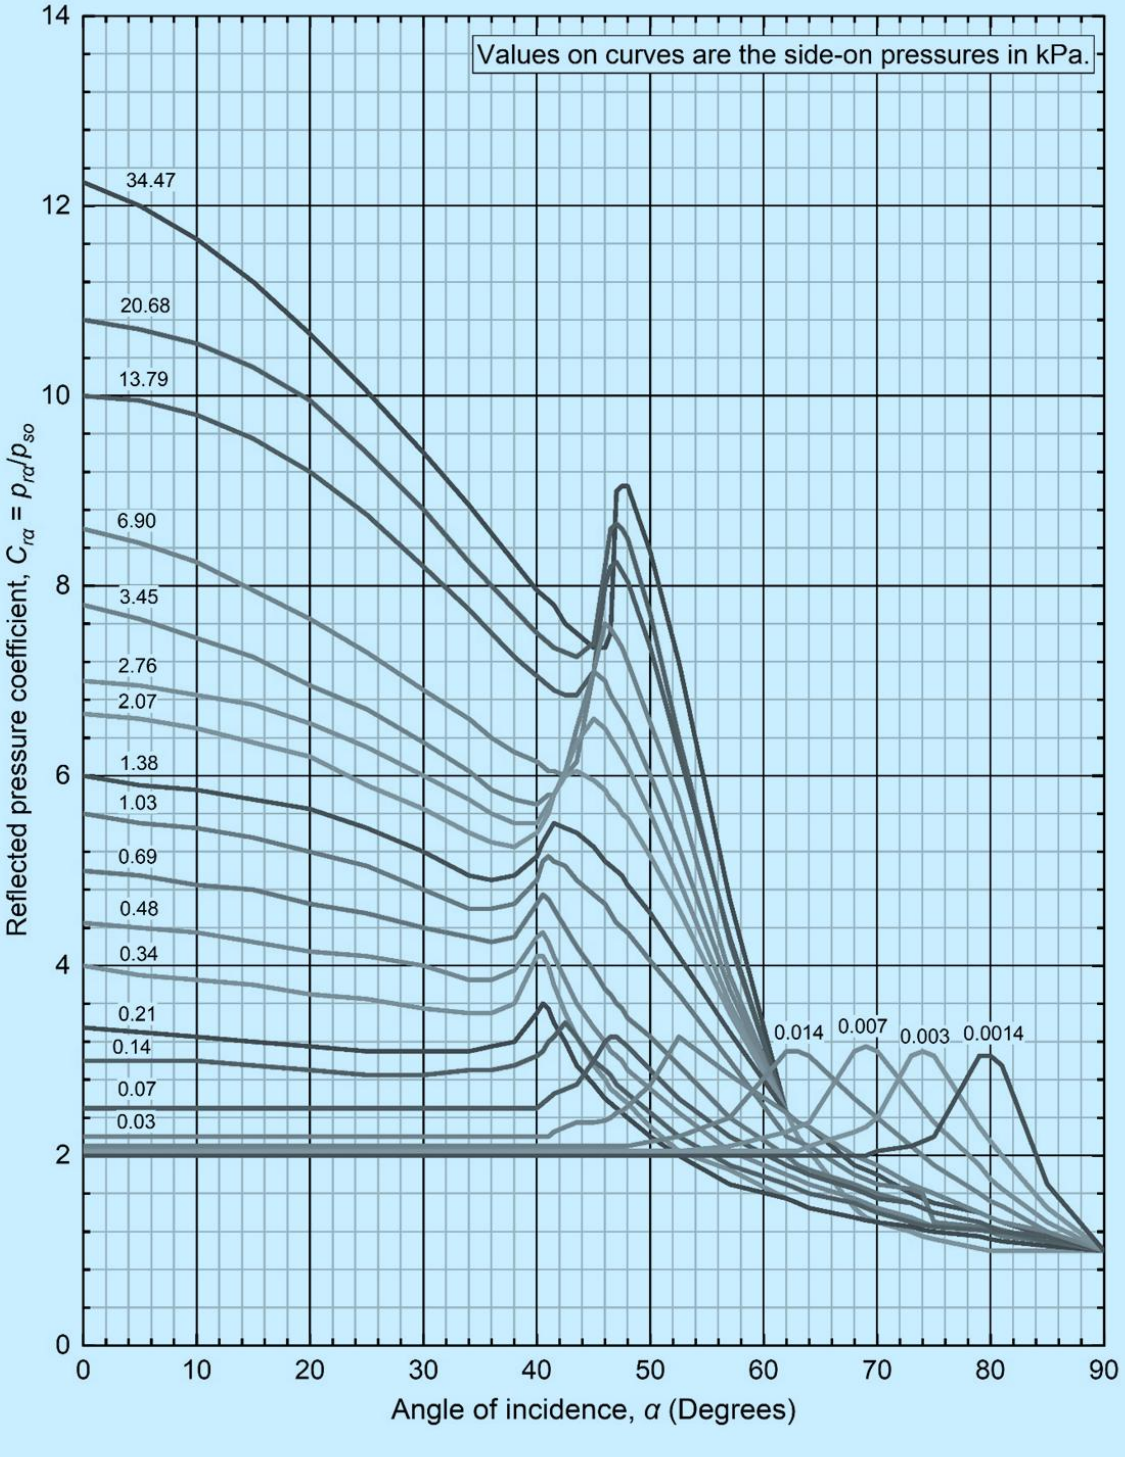

FIG. 34 INFLUENCE OF ANGLE OF INCIDENCE ON THE REFLECTED PRESSURE COEFFICIENT

L-6.5 Simplified Blast Pressure History

For the purpose of simplified analysis and design, the exponential pressure time relation in the positive phase may be idealised to a triangular pulse e as shown in Fig. 35.

The triangular pulse shall be constructed to have the same peak pressure as in the original exponential blast pressure curve and the positive phase duration (t_d) so adjusted that the area under the curve remains unchanged.

The usage of triangular representation of pressure history shall be governed by relevant provisions in this annex.

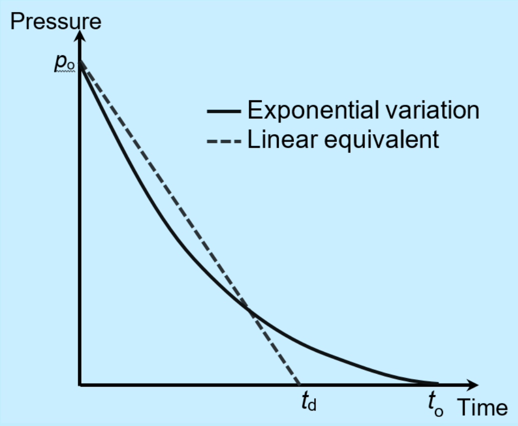

FIG. 35 SIMPLIFIED TRIANGULAR REPRESENTATION OF THE EXPONENTIAL OVERPRESSURE HISTORY

L-6.6 Ground Shocks

L-6.6.1 *Ground Shaking Intensity*

The scaled peak particle displacement, peak particle velocity and soil pressure generated by surface explosion shall be estimated using following equations:

Scaled peak particle displacement:

$$\frac{x}{M^{1/3}} = 60\frac{f}{c}\left(\frac{2.5R}{M^{1/3}}\right)^{1-n}$$

$$\text{Soil pressure, } p = 160 f \rho c \left(\frac{R}{M^{1/3}}\right)^{-n}$$

where

f = coupling factor;

n = attenuation coefficient;

M = explosive weight;

ρ = soil density;

c = soil seismic velocity; and

R = standoff distance.

Table 47 shall be used for taking the values of c, ρc and n.

The coupling factor f shall be taken as 0.14 for explosions above ground.

vi)	Heavy saturated clays and clay shales	<1524	3.40 to 4.07	1.5

L-6.6.2 *Safe Ground Particle Velocity*

For safety of buried and semi-buried structures, the peak particle velocity, u, as calculated using equation provided in **L-6.6.1** shall not exceed the values given in Table 48.

Table 48 Safe Ground Particle Velocity

L-6.7 Confined Explosions

The provisions given here are applicable for scenarios where detonation of explosives takes place inside closed spaces.

For the purpose of evaluating blast load effects, confined explosions are categorized into:

a) fully vented; and

b) partially vented.

The examples of fully and partially vented structures are shown in Fig. 36.

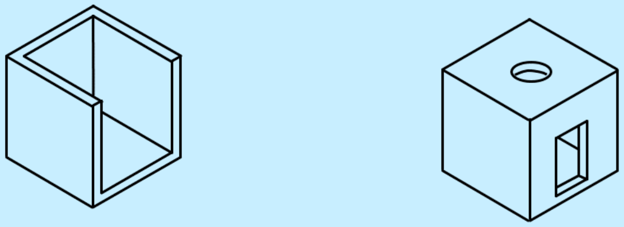

FIG. 36(A) FULLY VENTED

FIG. 36(B) PARTIALLY VENTED

FIG. 36 CONFINED EXPLOSION SCENARIO

The variation of pressure at any location inside a closed space due to detonation inside the closed space is obtained using the following assumptions:

a) surfaces internal structural members are subjected to shock waves from multiple reflections characterized by multiple peaks; and

b) shock pressure is followed by development of gas pressure of small peak overpressures but significantly longer durations.

The provisions of **L-6.7** are only applicable when following conditions are satisfied:

a) structure is of regular geometric shape; and

b) the effect of confined detonation is being evaluated at scaled distances greater than 3 m/kg$^{1/3}$.

L-6.7.1 *Fully Vented Structures*

Fully vented structures are to be primarily subjected to shock pressures and the effect of gas pressures may be neglected. The reflected overpressure history at any point inside the structure is represented in Fig. 37. The peak pressure and impulse for the first pulse may be obtained using the procedure described in **L-6.3** as a case of direct reflection of the blast wave propagating from the centre of detonation to the point of interest. The second and the third triangular pulse shall be constructed from the characteristics of the first pulse.

Further simplification of pressure variation in Fig. 37 is allowed if the ratio of total load duration ($5t_a + t_d$) to the time-period of the structure is smaller than 0.1. In such cases, the three pulses of pressure history in Fig. 37 may be combined into a single pulse of peak pressure 1.75 p_{ro} and duration equal to t_d.

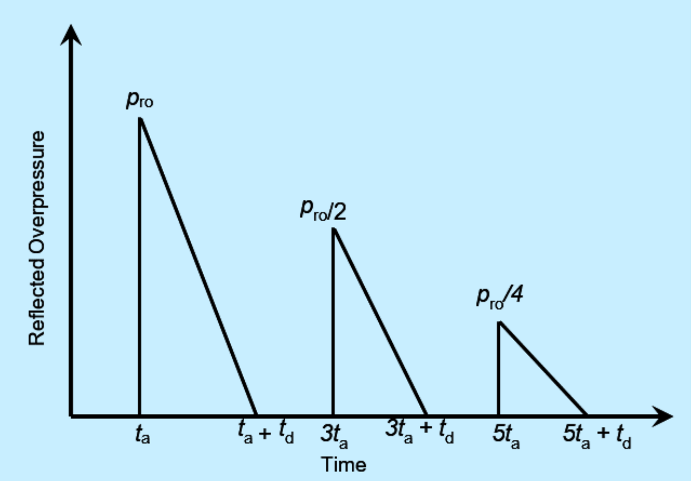

FIG. 37 REFLECTED OVERPRESSURE HISTORY FOR CONFINED DETONATION IN A FULL-VENTED SPACE

L-6.7.2 *Partially Vented Explosion*

Partially vented explosions are characterized by long duration gas pressures with minor effect of the shock pressures.

Wherever, required, the arrival time of the peak gas pressure is taken as the end time of the shock phase, that is, $5t_a + t_d$, as determined in **L-6.7.1**.

The blast load effects of confined explosion in partially vented structure is evaluated using advanced numerical technique as per the provisions of **L-8.3.3**.

The interior surface of a partially vented structure subject to confined explosion may conservatively be designed for the peak gas overpressure, p_g, which needs to be applied statically.

This peak gas overpressure is obtained from the chart in Fig. 38. The use of charts requires following condition to be satisfied:

$$0 \leq A / V_f^{2/3} \leq 0.022$$

where

A = structure's total vent area; and

V_f = free volume which shall be calculated as the total volume excluding the volume of all interior equipment and structural elements.

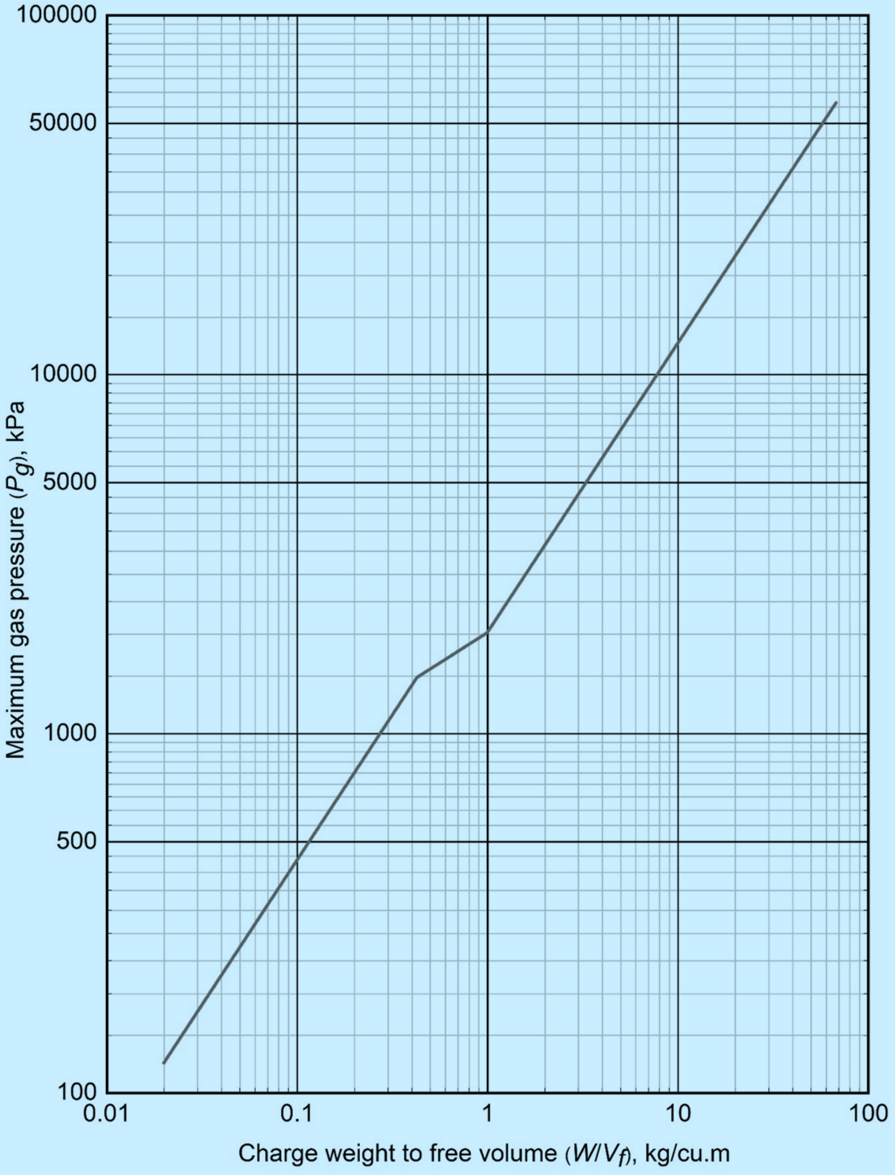

FIG. 38 PEAK GAS PRESSURE PRODUCED BY A TNT DETONATION IN A PARTIALLY VENTED STRUCTURE

L-7 EFFECTS OF BLAST ON STRUCTURES

L-7.1 Above Ground Structures

L-7.1.1 *Types of Structures*
Structures are categorized into following two types for the purpose of determining its interaction with the blast wave and calculating effective blast overpressure history:

a) *Diffraction type structures* — These are the closed structures without openings, with the total area opposing the blast. These are subjected to both the shock wave overpressure p_{so} and the dynamic pressures q caused by blast wind; and

b) *Drag type structures* — These are the open structures composed of elements like beams, columns, trusses, etc, which have small projected area opposing the shock wave. These are mainly subjected to dynamic pressures q.

L-7.1.2 *Closed Rectangular Structures*

L-7.1.2.1 *Front face*

The peak reflected overpressure at any point on the front face of a closed rectangular structure shall be obtained using the following equation.

$$p_{r\alpha} = C_{r\alpha} p_{so}$$

where

p_{so} = peak side-on pressure that shall be obtained using Fig. 30 and Fig. 31 for spherical and hemispherical detonations, respectively, using the effective scaled distance; and

$C_{r\alpha}$ = reflection co-efficient, which shall be determined from Fig. 34 using the angle of reflection and the side-on pressure.

It is permitted to neglect spatial variation of pressure on the front face by assuming an equivalent uniform reflected overpressure which is equal to the peak reflected overpressure on the front face that is closest to the point of detonation. This, under most scenario, corresponds to the peak reflected overpressure, p_{ro}, at normal incidence ($\alpha = 0$ degrees).

The reflected overpressure, p_r, on the front face drops from the peak value p_{ro} to zero in time t_{rf}, whichever, is calculated as, $t_{rf} = 2i_{ro}/p_{ro}$, where p_{ro} and i_{ro} shall be obtained from using Fig. 30 and Fig. 31 for spherical and hemispherical detonations, respectively.

The stagnation overpressure, p_s, at the edges of the front face drops from the peak value, $p_{so} + C_d q_o$, to zero in time t_{of}, whichever, is calculated as, $t_{of} = 2i_{so}/p_{so}$, where p_{so} and i_{so} shall be obtained using Fig. 30 and Fig. 31 for spherical and hemispherical detonations, respectively. The drag coefficient, C_d, shall be taken as 1.0. The peak dynamic pressure, q_o, shall be determined from Fig. 32.

The reflected overpressure acting at a point on the front face drops from the peak value p_{ro} to overpressure ($p_{so} + C_d q$) in clearance time t_c or t_{of}, whichever, is less (*see* Fig. 40).

The drag coefficient, C_d, for different faces of closed rectangular structures located above ground shall be taken as per Table 51.

The clearing time, t_{cp}, for a point on the front wall is given by

$$t_{cp} = \frac{3S}{U}$$

where

S = H or W/2 whichever, is less (*see* Fig. 39); and

U = shock front velocity to be obtained from using Fig. 30 and Fig. 31 for spherical and hemispherical detonations, respectively.

The average clearing time, t_c, required to clear the front face of reflection effects from the roof down and inwards from the sides shall be calculated using the following expression:

$$t_c = \frac{4HW}{C_r(W+2H)}$$

where

C_r = velocity of sound in the reflected overpressure region that shall be determined using Fig. 33.

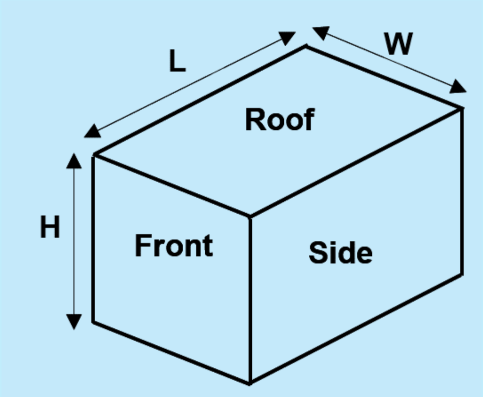

FIG. 39 ABOVE GROUND RECTANGULAR STRUCTURE

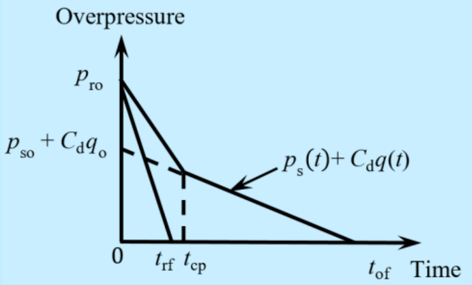

FIG. 40 REFLECTED OVERPRESSURE AT A POINT ON THE FRONT SURFACE OF FINITE REFLECTING SURFACE

The average net loading on the front face ($W \times H$) as a function of time is shown in Fig. 41 depending on whether t_c is smaller than or equal to t_{of}. The pressures p_{ro}, p_{so} and q, the impulses t_{ro} and I_{so} are for the actual explosion that are determined according to **L-6.3**.

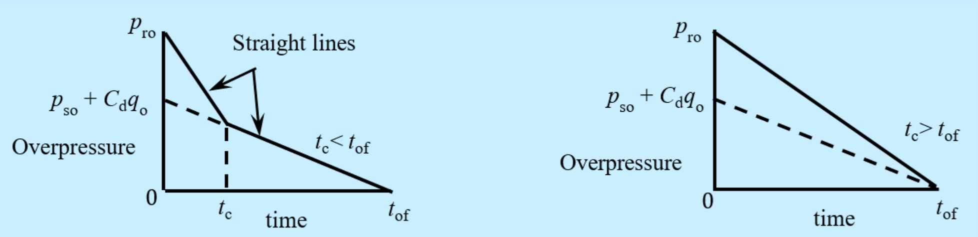

FIG. 41 REFLECTED OVERPRESSURE HISTORY ON THE FRONT FACE OF A CLOSED RECTANGULAR STRUCTURE

L-7.1.2.2 *Rear face*

Using the pressures for the actual explosion, the average loading on the rear face ($W \times H$) in Fig. 39 shall be taken as shown in Fig. 42, where the time has been taken from the instant the shock first strikes the front face. The time intervals of interest are the following:

$\frac{L}{U}$ = the travel time of shock from front to rear face; and

$\frac{4S}{U}$ =pressure rise time on the back face.

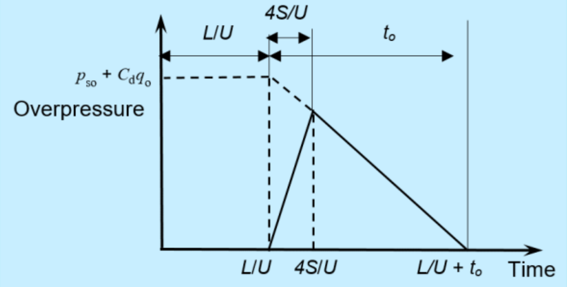

FIG. 42 OVERPRESSURE VERSUS TIME FOR REAR FACE

L-7.1.2.3 *Roof and side walls*

The average pressure versus time curve for roof and side walls is given in Fig. 43(A) when t_d is greater than the transit time $t_t = L/U$. When t_t is greater than t_d, the load on roof and side walls may be considered as a moving triangular pulse having the peak value of overpressure $p_{so}+C_d q_o$ and time t_o as shown in Fig. 43(B).

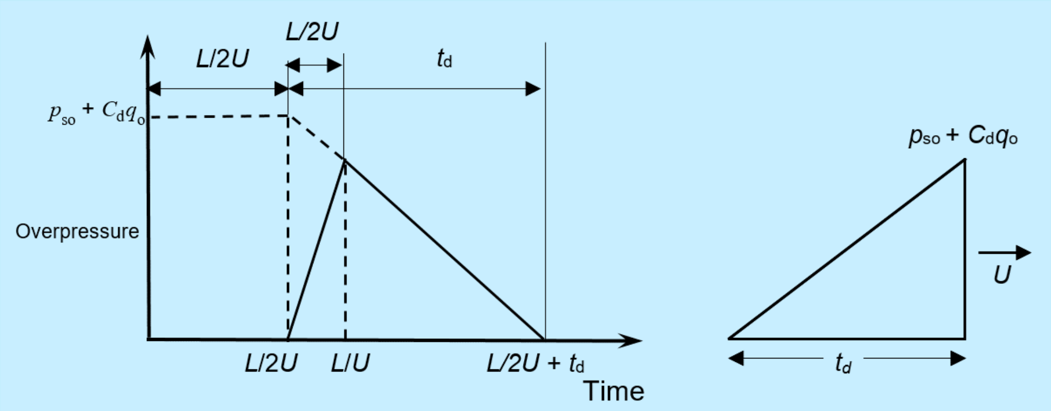

FIG. 43(A) AVERAGE PRESSURE DIAGRAM $t_d > t_t$

FIG. 43(B) MOVING PRESSURE PULSE FOR $t_t > t_d$

FIG. 43 OVERPRESSURE VERSUS TIME FOR ROOF AND SIDE WALLS

Table 51 Drag Coefficient C_d

(*Clause* L-7.1.2.1)

Sl No. (1)	**Shape of Element** (2)	**Drag Coefficient C_d** (3)	**Remarks** (4)
i)	Front vertical face	1.0	
ii)	Roof, near and side faces for:		For closed rectangular structures located above ground
	a) q_o = 0 kPa to 170 kPa	- 0.4	
	b) q_o = 170 kPa to 350 kPa	- 0.3	
	c) q_o = 350 kPa to 1 MPa	- 0.2	

L-7.1.2.4 *Overturning of structure*

The average net load as a function of time which tends to cause sliding and overturning of the building is obtained by subtracting the loading on back face from that on the front face.

L-7.1.3 *Closed Cylindrical Arch-Shape Structures*

L-7.1.3.1 *Gable ends*

The loading may be taken same as for front and rear faces of above ground rectangular structure.

L-7.1.3.2 *Curved surface*

The direction of shock wave propagation is taken transverse to the ridge of the structure and since the usual arch spans are large so that the transit time t_t is greater than the positive phase time t_d, average loading condition cannot be assumed. Therefore, the loading on curved surface may be taken as a moving triangular pulse as shown in Fig. 43(B).

L-7.1.3.3 *Closed dome structures*

The loading on a domical structure may be taken as a moving triangular pressure pulse as shown in Fig. 43(B). The variation of pressure transverse to the direction of propagation of the pulse may be considered symmetrical varying according to cosine θ where the angle θ is measured from longitudinal vertical section of the dome, as shown in Fig. 44.

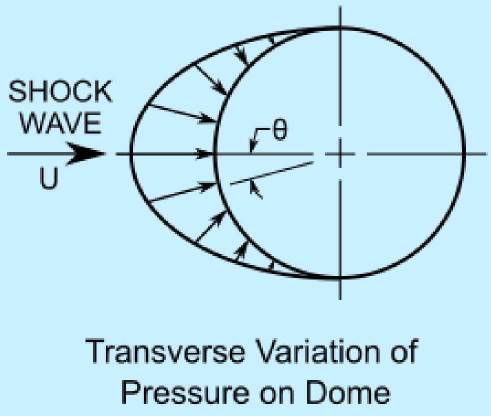

FIG. 44 TRANSVERSE VARIATION OF PRESSURE ON DOME

L-7.2 Blast Load on Below-Ground Structures

L-7.2.1 *Types of Structures*

The below-ground structures are classified into buried and semi-buried structures depending upon the earth cover and slopes of earth berms. The buried structures are subjected only to the general overpressure p_{so}, the reflected and dynamic pressures being neglected. The semi-buried structures are subjected to partial dynamic pressures besides the general overpressure. Both are acted upon by air-induced ground shock also.

For assessing the effects of above-ground blasts on below-ground structures, dynamic finite element analysis can be performed considering the flexibility of soil and interactions of blast induced ground waves with the structure.

L-8 RESPONSE OF STRUCTURAL ELEMENTS

L-8.1 Properties of Materials

The nominal properties of materials are obtained as per relevant codes and guidelines. The change in material properties due to high strain rates associated with blast response are to be incorporated using the provisions in **L-8.1.1** and **L-8.1.2**.

L-8.1.1 *Elastic Modulus and Poisson's Ratio*

The elastic modulus and Poisson's ratio of the constituent materials used in the structural elements shall be estimated based on relevant standards as applicable to that material.

No increase in elastic modulus and Poisson's ratio is to be considered for the calculation of blast response of structures.

L-8.1.2 *Dynamic Strength*

L-8.1.2.1 *Design strength of structural steel*

The average dynamic increase factors of strength for structural, carbon, mild, weldable or rivet steels and high strength alloy steels are listed in Table 52 and Table 53.

Table 52 Dynamic Increase Factors for Mild Steels

(*Clause* L-8.1.2.1)

iii)	Ultimate strength in flexure	1.1
iv)	Ultimate strength in compression, diagonal tension, direct shear and bond	1.0

L-8.1.2.3 *Design strength for masonry or plain concrete*

The average dynamic strength increase factors for masonry and plain concrete are listed in Table 56.

Table 56 Dynamic Increase Factors for Masonry and Plain Concrete

(*Clause* L-8.1.2.3)

Sl No. (1)	Strength (2)	Dynamic Increase Factors (3)
i)	Flexure	1.15
ii)	Compression	1.10
iii)	Diagonal tension and direct shear and bond	1.00

L-8.1.3 *Design Strength*

For obtaining design strength, the resistance of various elements is to be estimated using the strength increased by the dynamic increase factors mentioned in Q-8.1.2.

L-8.1.4 *Deformation Limits*

Structural elements subjected to blast loading can be designed subject to certain allowable dynamic ductility ratios and support rotations.

The blast resistance of a flexural member is to be expressed in terms of maximum permissible deflection. Support rotation and ductility is to be used to characterize the blast resistance of reinforced concrete and structural steel members, respectively.

The support rotation shall be defined as per Fig. 45.

The maximum permissible deflection defines the energy absorption capacity of the element which is equal to the area under the resistance versus deflection curve. For a given blast scenario, greater the permissible deflection, lesser will be the maximum resistance required in the member.

The allowable deformation parameters are included in Table 57.

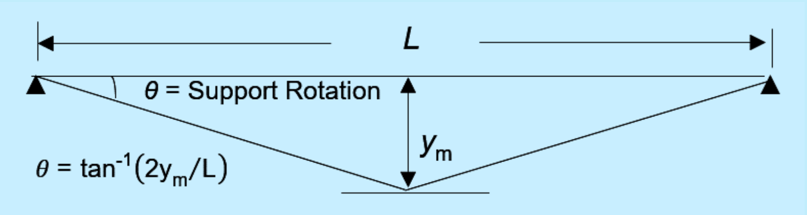

FIG. 45 SUPPORT ROTATION IN A FLEXURAL MEMBER

L-8.2 Modelling of Structural Members

L-8.2.1 *Geometry, Material and Boundary Conditions*

The methods of modelling are applicable to structural members of regular prismatic sections.

L-8.2.2 *Equivalent Single Degree of Freedom* (*SDOF*) *Model*

The structural element or system may be replaced by an equivalent single spring-mass system having effective stiffness k_{E} and effective mass equal to $K_{\mathrm{LM}}M_{\mathrm{t}}$, where M_{t} is the actual mass of the member under consideration and K_{LM} is a load-mass factor depending upon the stiffness and mass distribution in the member and its boundary conditions. The equivalent system is defined so that the deflection of the equivalent single mass is the same as that of some significant point in the given structure. The effective stiffness k_{E} is defined with respect to the deflection of this point.

The load-mass factor K_{LM} is equal to the ratio of mass factor K_{M} to the load factor K_{L}. The factors are evaluated on the basis of an assumed deflected shape of the structure as given below:

$$K_{\mathrm{M}} = \frac{1}{M_{\mathrm{t}}}\left\{\sum_{r=1}^{n} M_{\mathrm{r}}\emptyset_{\mathrm{r}}^{2} + \int m\emptyset^{2}(x)\,dx\right\}$$

$$K_{\mathrm{L}} = \frac{1}{P_{\mathrm{t}}}\left\{\sum_{r=1}^{j} p_{\mathrm{r}}\emptyset_{\mathrm{r}} + \int p(x)\emptyset(x)dx\right\}$$

where

n = number of concentrated masses;

M_r = concentrated mass at point r ;

M_t = total actual mass;

$\phi_r\phi_r$ = deflection at point r of an assumed deflected shape for concentrated loads;

m = distributed mass intensity per unit length;

$\phi_{(X)}$ = deflection at point x of an assumed deflected shape for distributed loads;

P_t = total dynamic load (at any instant of time);

j = number of concentrated load points;

P_r = concentrated dynamic force at point r; and

$p_{(X)}$ = intensity of distributed dynamic load per unit length.

L-8.2.2.1 *Effective single SDOF parameters*

Values of the factors k_E and K_{LM} for few structural members are given in Table 58 to Table 60. The effective SDOF parameters for other type of structural members shall be calculated by assuming an appropriate deflected shape as per **L-8.2.2.2**.

L-8.2.2.2 *Deflected shape*

The deflected shape is suitably chosen to resemble as far as possible the true deflected shape taking into consideration whether the structure or member remains elastic or goes into the plastic range. It may be taken the same as due to static application of the dynamic load on the structure. The deflected shape is normalized such that $\varphi(x)=1$ at the point with respect to which the effective stiffness k_E is defined.

L-8.2.2.3 *Effective time-period*

The effective time period T of the structural member may be calculated from the equation:

$$T = 2\pi\sqrt{\frac{K_{LM}\,M_t}{k_E}}$$

L-8.2.3 *Resistance Function*

The resistance versus deflection diagram of a structural element shall be idealized as elasto-plastic (*see* Fig. 46) by keeping the area under the actual and idealized curves about the same up to the maximum permissible deflection defined as per **L-8.1.4**.

FIG. 46(A) GENERAL NONLINEAR

FIG. 46(B) TRILINEAR

FIG. 46 IDEALIZATION OF RESISTANCE DEFLECTION DIAGRAM

A trilinear resistance versus deflection diagram may be simplified to its elasto-plastic (bilinear) equivalent of same peak resistance (R_m) and the elastic parameters calculated using following equations:

$$y_E = y_e + y_p \left(1 - \frac{R_m}{R_e}\right)$$

$$k_E = \frac{R_m}{y_E}$$

L-8.3 Methods of Analysis

These provisions apply to structures, components and systems subject to near-field and far-field detonations but not for contact or near-contact detonations.

L-8.3.1 *Analysis of Members*

Blast loaded structural components of a structure may be analysed independently provided it can be demonstrated that such independent member analysis would yield conservative performance of the member and the structure.

L-8.3.1.1 *Equivalent SDOF analysis*

The equivalent SDOF analysis may be used to determine response of structural members subject to blast loads when the following criteria are satisfied:

a) The equivalent mass, stiffness and damping parameters in the model must capture the dynamic response and failure mode of the structural member being analysed; and

b) A single flexural deformation mode controls the dynamic response of the structural system.

The equivalent SDOF analysis shall make use of following parameters:

a) Blast-pressure history obtained using L-6.3;

b) The effective time-period calculated using L-8.2.2.3;

c) Resistance function of the structural element established using provisions of L-8.2.3; and

d) Maximum permissible deflection provided in L-8.1.4.

L-8.3.1.2 *Blast overpressure history*

The exponential blast pressure history of Fig. 28 shall be idealized to a triangular pulse [Fig. 47(A) as per provisions of **L-6.5** for the purpose of obtaining equivalent SDOF blast loads. Such idealization may neglect the effect of negative phase, unless otherwise it is expected to influence the flexure response of the structural member.

The positive phase duration of the triangular loading shall be calculated as:

$$t_\mathrm{d} = \frac{2i_{ro}}{p_{ro}}$$

If the influence of clearing on the blast pressure history applied to the front face of the structural element is found to be significant, then the equivalent SDOF blast loads shall be idealized to Fig. 47(B) using **L-7.1.2**.

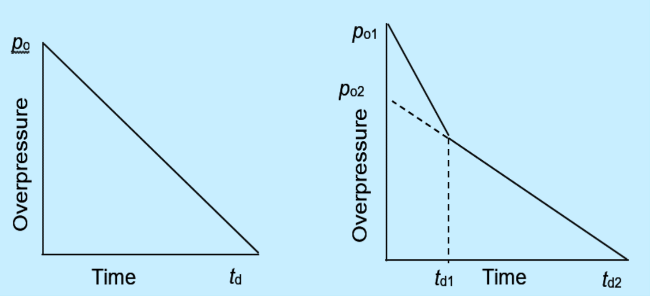

FIG. 47(A) LINEAR

FIG. 47(B) BILINEAR

FIG. 47 IDEALIZED BLAST PRESSURE HISTORIES

When the ratio of time duration t_{d1}, or t_{d2}, to the natural period of the element is less than 0.1, the problem may be considered as an impulse problem taking the area under the pressure versus time curve as impulse per unit area. In such a case, the shape of pressure-time curve is not important.

L-8.3.1.3 *Uniform blast pressure distribution*

A uniform distribution of blast pressure over the length of the structural member may be considered provided one of the following conditions are satisfied:

a) The minimum scaled distance to the structural component is greater than 1.2 m/kg$^{1/3}$; and

b) The variation of peak reflected pressures over the middle two-third of the component span length is less than 25 percent.

   For uniform distribution of blast pressure, the pressure value calculated at the closest point on the structure from the centre of detonation may be considered over the whole reflecting surface.

L-8.3.1.4 *Non-uniform blast pressure distribution*

For members subjected to spatially non-uniform blast loads, the effect of non-uniformity on the response shall be considered.

These provisions shall be applicable for non-uniform blast pressure distribution, provided the conditions outlined in **L-8.3.1.3** are not satisfied and the minimum scaled distance to the structural component is between 0.4 m/kg$^{1/3}$ and 1.2 m/kg$^{1/3}$.

An equivalent impulse weighted using deflected shape function shall be considered for the structural component as per following expression:

$$i_e = \frac{\int_0^L \int_0^H i(x,y)\phi(x,y)dxdy}{\int_0^L \int_0^H \phi(x,y)dxdy}$$

where

i_e = equivalent impulse of uniformly distributed load;

L = length of loaded area;

H = width of loaded area;

$\emptyset(x,y)$ = deflected shape function of blast-loaded component; and

$i(x,y)$ = non-uniform impulse applied to loaded area.

The simplified triangular representation of the pressure time history shall be constructed as per provisions of **L-6.5** by calculating the positive loading phase duration using the equivalent uniform impulse (i_e) and the peak overpressure at the midspan or geometric centre of the reflecting surface.

A safety factor of 1.25 shall be used if a non-uniform blast load is represented as an equivalent uniform impulse in a blast analysis.

L-8.3.1.5 *Elastic SDOF response*

For elastic analysis (ductility ratio $\mu \leq 1.0$) of structures, the effective stiffness k_E and load mass factor K_{LM} shall be used as given in Table 58 to Table 60.

For elastic response of an SDOF system, the peak response (y_m) and the time to peak response (t_m) may be obtained using following expressions:

$$\frac{y_m}{y_0} = 2 - \frac{t_m}{t_d}; \qquad \text{when } t < t_d$$

$$t_m = \frac{2}{\omega}\tan^{-1}(\omega t_d) \qquad \text{when } t < t_d$$

$$\frac{y_m}{y_0} = \frac{1}{\omega t_d}\sqrt{2(1-\cos\omega t_d - \omega t_d \sin\omega t_d) + (\omega t_d)^2}; \qquad \text{when } t > t_d$$

$$t_m = \frac{1}{\omega}\tan^{-1}\left(\frac{1-\cos\omega t_d}{\sin\omega t_d - \omega t_d}\right) \quad \text{when } t > t_d$$

where

y_m = peak elastic displacement;

y_o = peak static displacement; and

t_m = time to the peak displacement.

L-8.3.1.6 *Inelastic SDOF response*

For elasto-plastic analysis, k_E shall be used as given in Table 58 to Table 60 but value of K_{LM} may be chosen in between the elastic and plastic cases depending upon the ductility factor.

Based on the elasto-plastic resistance-deflection curve shown in Fig. 46 and triangular pressure-time curve shown in Fig. 47(A), the ratio of resistance R_m, required to the peak dynamic load (F_1) is given in Fig. 48 for various values of t_d/T and µ.

The time to peak deflection (t_m)shall be obtained from Fig. 49 for various values of td/T and µ.

When the time ratio, t_d/T, is less than 0.1, the ratio k may be computed from the following equation:

$$k = \frac{\pi}{\sqrt{2\mu - 1}} \cdot \frac{t_d}{T}$$

When the pressure-time diagram is given by Fig. 47B, the following equation shall be satisfied:

$$\frac{P_{01}}{R_m}k_1+\frac{P_{02}}{R_m}k_2=1$$

where

R_m = the required resistance; and

k_1, k_2 = the values of ratios k for ductility ratio μ and time ratios t_{d1}/T and t_{d2}/T respectively.

For elasto-plastic design of fixed slabs, the modified value of k_E is to be worked out in accordance with Fig. 46(B) using the stiffness values of slab in elastic and elasto-plastic cases as given in Table 60 and K_{LM} is to be suitably chosen depending upon the ductility factor.

The value of modular ratio shall be taken the same as in static design for calculating EI.

For calculating moment of inertia I of reinforced concrete sections, the concept of effective transformed area shall be used.

For analysis of reinforced concrete sections when the simplified elasto-plastic resistance function is used, the elastic stiffness shall be based on effective moment of inertia that shall be calculated as the average of the gross moment of inertia of the transformed section and the cracked moment of inertia.

The gross and cracked moment of inertias shall be obtained from Fig. 50.

FIG. 50 CRACKED MOMENT OF INERTIA OF PRISMATIC SECTIONS

L-8.3.2 *MDOF Analysis*

The multi degree of freedom (MDOF) analysis is permitted for structural systems which cannot be analysed using the simplified SDOF analysis, provided the expected failure mechanism under blast load can adequately be represented using the MDOF model representation.

L-8.3.2.1 The numerical model of MDOF system may comprise of distributed elements or combined lumped mass and stiffness elements.

L-8.3.2.2 The spring in the lumped-mass stiffness should adequately represent the member resistance-deflection behaviour by incorporating appropriate constitutive relationship.

L-8.3.2.3 The lumped-mass stiffness system should be able to properly account for the dynamic behaviour and failure modes at the structure and the element level.

L-8.3.2.4 The use of structural damping is permitted for MDOF system when the expected response is within elastic range. These structural damping values for elastic response shall conform to the typical values used for different type of structures.

L-8.3.2.5 The energy dissipation during inelastic response should be accounted by using appropriate nonlinear member resistance-deflection curves. Supplemental damping in form of structural damping is not permitted for nonlinear range of response.

L-8.3.2.6 The time-step for MDOF analysis shall be determined based on accuracy and convergence requirement. The time-step should be sufficiently small such that it captures the rise and decay of the applied blast load time history.

L-8.3.3 *Finite Element Analysis*

Advanced numerical analysis techniques, such as explicit dynamic finite element analysis (FEA), may be used to analyse structures subject to blast loading, if the methods described in **L-8.3.1** and **L-8.3.2** cannot be reliably used to obtain the response. Such methods shall be required if one or more of the following conditions are encountered:

a) detonation involves scaled distances smaller than 0.4 m/kg$^{1/3}$;
b) detonation of non-spherical charge masses at scaled distances smaller than 3 m/kg$^{1/3}$;
c) the blast wave propagation involves interaction with surrounding environment before it reaches the location of interest;
d) the variation in geometric and material properties of structural elements or the structure cannot appropriately be represented using the simplified methods; and
e) the interaction between the blast wave and structure is of significance and the assumption of rigid reflecting surface is not valid.

The FEA shall consider the modelling of non-ductile failure modes and failure surfaces that cannot be considered in the simplified SDOF and the MDOF methods of analysis.

The time-step of analysis need to be decided based on size of the smallest element of interest with appropriate consideration to the accuracy and convergence of the response.

The interaction of blast load with the surrounding shall be considered using computational fluid dynamics (CFD) methods.

Where the shape and size of the charge mass is expected to play a major role in the detonation process and the resulting blast load, the detonation process itself may be modelled.

The FEA methods shall not be subjected to the response limits typically used for structural members in the simplified SDOF and the MDOF analysis.

Range (OA) = moment at centre of long edge just becomes plastic;
Range (OB') = moment at supports and mid-span sections just becomes plastic;
M^o_{psb} = negative ultimate moment capacity per unit width at centre of long edge;
M_{psa} = total negative ultimate moment capacity along a short edge support;
M_{psb} = total negative ultimate moment capacity along a long edge support;
M_{pfa}, M_{pfb}, I, P_t = (*see* Table 46);
V_A = total dynamic reaction along a short edge; and
V_B = total dynamic reaction along a long edge.

L-9 LOAD COMBINATIONS FOR DESIGN

L-9.1 Partial Safety Factor

A partial safety factor of unity shall be assumed for blast loads.

L-9.2 Imposed loads

Imposed load on floors shall be considered as per **3**. No Imposed load shall be considered on roof at the time of blast.

L-9.3 Load Combination

Wind or earthquake forces shall not be assumed to occur simultaneously with blast effects. Effects of temperature and shrinkage shall be neglected.

Following load combinations for limit state design shall be considered:

$$1.0DL + 0.5IL + 1.0B$$
$$0.9DL + 1.0B$$

where

DL = design dead load;

IL = design imposed load; and

B = design blast load.

L-10 For design of structures for blast effects of explosions above ground, *see also* good practice [C-1(16)].

For safety of structures during underground blasting, *see also* good practice [C-1(17)].

ANNEX M

(*Clause* 10.2.2 *and* *Table* 61)

SUMMARY OF DISTRICTS HAVING SUBSTANTIAL MULTI-HAZARD RISK AREAS

State	*Name of Districts Having Substantial Multi-Hazard Prone Area*			
	E.Q. and Flood	Cyclone and Flood	E.Q., Cyclone and Flood	E.Q. and Cyclone
(1)	(2)	(3)	(4)	(5)
Andhra Pradesh	Adilabad, Karim Nagar, Khammam	Krishna, Nellore, Srikakulam, Visakhapatnam, Vizianagram	East Godavari, Guntur, Prakasam, West Godavari	—
Assam	All 22 districts listed in Table 61 could have M.S.K IX or more with flooding	No cyclone, but speed can be 50 m/s in districts of Table 61 causing local damage except Dhubri	—	—
Bihar	All 25 districts listed in Table 61	—	—	—
Goa	—	—	—	North and South Goa
Gujarat	Banaskantha, Danthe GS, Gandhinagar, Kheda, Mahesana, Panchmahals, Vadodara	—	Ahmedabad, Bharuch, Surat, Valsad	Amreli, Bhavnagar, Jamnagar, Rajkot, Junagad, Kachcha
Haryana	All 8 districts listed in Table 61	—	—	—
Kerala	Idduki, Kottayam, Palakkad, Pathanamthitta	—	Alappuzha, Ernakulum, Kannur, Kasargod, Kollam, Kozhikode, Malappuram, Thiruvanathapura, Thrissur	—
Maharashtra	—	—	—	Mumbai, Rayagad, Ratnagiri, Sindhudurg, Thane
Orissa	—	Ganjam	Baleshwar, Cuttack, Puri	Dhenkanal
Punjab	All 12 districts listed in Table 61	—	—	—
Uttar Pradesh and Uttarakhand	All 50 districts listed in Table 61	—	—	—
West Bengal	Birbhum, Darjeeling, Jalpaiguri, Cooch Behar, Malda, Murshidabad, West Dinajpur	—	Bardhaman, Kolkata, Hugli, Howrah, Midnapore, Nadia, North and South 24 Parganas	Bankura
Union Territories	Delhi	—	Yanam (Py)	Diu
India	**139 Districts**	**6 Districts**	**29 Districts**	**16 Districts**

Table 61 Multi-Hazard Prone Districts

(*Annex* M)

Assam

Barpeta, Bongaigaon, Cachar[1], Darrang, Dhemaji, Dhuburi, Dibrugarh, Goalpara, Golaghat, Hailaknadi[1], Jorhat, Kamrup, Karbianglong, Karimganj[1], Kokrajhar, Lakhimpur, Morigaon, Nagaon, Nalbari, Sibsagar, Sonitpur, Tinsukia

Bihar[2]

Araria, Begusarai, Bhagalpur, Bhojpur, Darbhanga, Gopalganj, Katihar, Khagaria, Kishanganj, Madhepura, Madhubani, Munger, Muzaffarpur, Nalanda, Nawada, Paschim Champaran, Patna, Purbachamparan, Purnia, Samastipur, Saran, Saharsa, Sitamarhi, Siwan, Vaishali

Haryana[3]

Ambala, Bhiwani, Faridabad, Gurgaon, Hisar, Jind, Kurukshetra, Rohtak

Punjab[4]

Amritsar, Bathinda, Faridkot, Firozpur, Gurdaspur, Hoshiarpur, Jalandhar, Kapurthala, Ludhiana, Patiala, Rupnagar, Sangrur

Uttar Pradesh and Uttarakhand[5]

Agra, Aligarh, Allahabad, Azamgarh, Bahraich, Ballia, Barabanki, Bareilly, Basti, Bijnor, Budaun, Bulandshahr, Deoria, Etah, Etawah, Faizabad, Farrukhabad, Fatehpur, Firozabad, Ghaziabad, Ghazipur, Gonda, Gorakhpur, Hardoi, Haridwar, Jaunpur, Kanpur (Dehat), Kanpur (Nagar), Kheri, Lucknow, Maharajganj, Mainpuri, Mathura, Mau, Meerut, Mirzapur, Mordabad, Muzaffarnagar, Nainital, Pilibhit, Partapgarh, Raebareli, Rampur, Saharanpur, Shahjahanpur, Siddarth Nagar, Sitapur, Sultanpur, Unnao, Varanasi

---

[1] Districts liable to cyclonic storm but no storm surge

[2] No cyclonic storm in Bihar

[3] No cyclonic storm in Haryana

[4] No cyclonic storm in Punjab

[5] No cyclonic storm in Uttar Pradesh and Uttarakhand

ANNEX N

[*Clause* 11.2]

STRUCTURAL DESIGN BASIS REPORT

N-1 This report shall accompany the application for Building Permit.

N-2 In case information on items (iii), (x), (xviii), (xix) and (xx) of Part 1 of SDBR not can be given at this time, it should be submitted at least one week before commencement of construction.

N-3 In case of reinforced concrete framed buildings, a certificate to the effect that the Part 3 of the SDBR will be completed and submitted at least one month before commencement of construction, shall be submitted with the application for building permit. In addition to the completed report, the following additional information shall be submitted, at the latest, one month before the commencement of construction:

a) Foundations:

  1) In case raft foundation has been adopted, indicate stiffness (K) value used for analysis of the raft;
  2) In case pile foundations have been used, give full particulars of the piles, type, diameter, length, capacity; and
  3) In case of high water table, indicate system of countering water pressure and indicate the existing water table and that assumed to design foundations.

  NOTE — The report/certificate of sub-surface investigation shall be duly considered and used in the preparation of foundation design and details.

b) Idealization for earthquake analysis:

  1) In case of a composite system of shear walls and rigid frames, give distribution of base shear in the two systems on the basis of analysis and that used for design of each system; and
  2) Indicate the idealization of frames and shear walls adopted in the analysis with the help of sketches.

c) Submit framing plans of each floor and in case of basements, indicate the system used to contain earth pressures.

N-4 The latest version of the Indian Standards with their amendments as indicated in the SDBR template given below, shall be referred for the preparation of the report.

N-5 The format of Part 1 of SDBR shall be as below:

PART 1 GENERAL DATA			
Sl No.	*Description*	*Information*	*Notes*
i)	Address of the building: a) Name of the building; b) Plot number; c) Subplot number, if any; d) Town Planning Scheme (if applicable): 1) Name; and 2) Number. e) Locality/Township; and f) District		
ii)	Name of owner		
iii)	Name of Building Constructor on record		

Sl No.	*Description*	*Information*	*Notes*
iv)	Name of Architect/Engineer on record		
v)	Name of Structural engineer on record		
vi)	Use of the building		
vii)	Number of storeys above ground level (including storeys to be added later, if any)		
viii)	Number of basements below ground level		
ix)	Type of structure: a) Load bearing walls; b) R.C.C frame; c) R.C.C frame and shear walls; and d) Steel frame.		
x)	Soil data: a) Type of soil; and b) Design safe bearing capacity.		IS 1892 IS 1904
xi)	Dead loads (Unit weight adopted): a) Earth; b) Water; c) Brick masonry; d) Plain cement concrete; e) Reinforced cement concrete; f) Floor finish; g) Other fill materials; and h) Piazza floor fill and landscape.		IS 875 (Part 1)
xii)	Imposed (Live) loads: a) Piazza floor accessible to fire tender; b) Piazza floor not accessible to fire tender; c) Floor loads[1]; and d) Roof loads[2].		IS 875 (Part 2)
xiii)	Cyclone/Wind: a) Speed; and b) Design pressure intensity.		IS 875 (Part 3)
xiv)	Other loads, if any		Relevant parts of IS 875
xv)	Seismic zone		IS 1893 (Part 1)
xvi)	Importance factor (*I*)		IS 1893 (Part 1)
xvii)	Earthquake zone factor (Z)		IS 1893 (Part 1)
xviii)	Elastic force reduction factor (*R*)		IS 1893 (Part 1)
xix)	Fundamental natural period (approximate)		IS 1893 (Part 1)

Sl No.	*Description*	*Information*	*Notes*
xx)	Horizontal site-specific acceleration PSA (A_{SS})		IS 1893 (Part 1)
xxi)	Expansion/Separation Joints[3]		

---

[1] Enclose small scale plans of each floor on A4 sheets

[2] In case terrace garden is provided, indicate additional fill load and imposed (live) load

[3] Indicate on a small scale plan on A4 sheet

N-7 The format of Part 3 of SDBR shall be as below:

PART 3 REINFORCED CONCRETE FRAMED BUILDINGS			
Sl No.	*Description*	*Information*	*Notes*
i)	Type of Building: a) Regular frames; b) Regular frames with shear walls; c) Irregular frames; d) Irregular frames with shear walls; and e) Soft storey.		IS 1893 (Part 1)
ii)	Number of basements		
iii)	Number of floors including ground floor		
iv)	Horizontal floor system: a) Beams and slabs; b) Waffles; c) Ribbed Floor; d) Flat slab with drops; and e) Flat plate without drops.		
v)	Soil data: a) Type of soil; b) Recommended type of foundation: 1) Independent footings; 2) Raft; and 3) Piles. c) Recommended bearing capacity of soil; d) Recommended, type, length, diameter and load capacity of piles; e) Depth of water table; f) Chemical analysis of ground water; and g) Chemical analysis of soil.		
vi)	Foundations: a) Depth below ground level; and b) Type of independent interconnected raft piles.		
vii)	System of interconnecting foundations: a) Plinth beams; and b) Foundation beams.		
viii)	Grades of concrete used in different parts of building		

Sl No.	*Description*	*Information*	*Notes*
ix)	Method of analysis used		
x)	Computer software used		
xi)	Torsion included		IS 1893 (Part 1)
xii)	Base shear:		IS 1893 (Part 1)
	a) Based on approximate fundamental period;		
	b) Based on dynamic analysis; and		
	c) Ratio of a/b.		
xiii)	Distribution of seismic forces along the height of the building		IS 1893 (Part 1) (provide sketch)
xiv)	The column of soft ground storey specially designed		IS 1893 (Part 1)
xv)	Clear minimum cover provided in:		IS 456
	a) Footing;		
	b) Column;		
	c) Beams;		
	d) Slabs; and		
	e) Walls.		
xvi)	Ductile detailing of RC frame:		
	a) Type of reinforcement used;		IS 456 IS 13920
	b) Minimum dimension of beams;		IS 13920
	c) Minimum dimension of columns;		IS 456
	d) Minimum percentage of reinforcement of beams at any cross-section;		IS 13920 IS 456
	e) Maximum percentage of reinforcement at any section of beam;		IS 13920
	f) Spacing of transverse reinforcement in 2-D length of beams near the ends;		IS 13920
	g) Ratio of capacity of beams in shear to capacity of beams in flexure;		IS 456
	h) Maximum percentage of reinforcement in column;		
	j) Confining stirrups near ends of columns and in beaL-column joints:		IS 13920
	1) Diameter; and		
	2) Spacing.		
	k) Ratio of shear capacity of columns to maximum seismic shear in the storey

N-8 The format of Part 4 of SDBR shall be as below:

PART 4 STRUCTURAL STEEL/STEEL CONCRETE COMPOSITE BUILDINGS			
i)	Adopted method of design	a) Simple; b) Semi-rigid; and c) Rigid.	IS 800
ii)	Design based on	a) Elastic analysis; and b) Plastic analysis.	IS 800 SP 6 (6)
iii)	Floor construction	a) Composite; b) Non-composite; and c) Boarded.	
iv)	Roof construction	a) Composite; b) Non-composite; c) Metal; and d) Any other.	
v)	Horizontal force resisting system adopted	a) Frames; b) Braced frames; and c) Frames and shear walls.	NOTE — Seismic force as per IS 1893 (Part 1) would depend on the system.
vi)	Slenderness ratios maintained	Members defined in IS 800	IS 800
vii)	Member deflection limited to	a) Beams, rafters; b) Crane girders; c) Purlins; and d) Top of columns.	IS 800
viii)	Structural members	a) Encased in Concrete; and b) Not encased.	IS 800
ix)	Proposed material	a) General weldable; b) High strength; c) Cold formed; and d) Tubular.	IS 2062 (Part 1) IS 801, IS 811 IS 806
x)	Minimum metal thickness specified for corrosion	a) Hot rolled sections	IS 800

	protection	b) Cold formed sections c) Tubes	
xi)	Structural connections	a) Rivets b) CT bolts c) HSFG bolts d) Black bolts e) Welding- Field/Shop (Specify welding type proposed) f) Composite	IS 800 IS 1929, IS 2155, IS 1148 IS 6639, IS 1367 IS 3757, IS 4000, IS 1363 IS 1367, IS 816, IS 814, IS 1395 IS 15977, IS 6419, IS 6560, IS 813, IS 9595 IS 11384
xii)	Minimum fire rating proposed, with method	a) Rating ___ hours; b) Method proposed: 1) Intumescent painting; 2) Spraying; 3) Quilting; and 4) Fire retardant boarding.	IS 1641, IS 1642, IS 1643

LIST OF STANDARDS

The following list records those standards which are acceptable as 'good practice' and 'accepted standards' in the fulfillment of the requirements of this NBCS. The latest version of a standard shall be adopted at the time of enforcement of this NBCS. The standards listed may be used by the Authority as a guide in conformance with the requirements of the referred clauses in this NBCS.

In the following list, the number appearing in the first column within parentheses indicates the number of the reference in this Section.

	IS No.	*Title*
(1)	IS 8888 : 2020	Requirements of low income housing for urban areas — Guide (*second revision*)
(2)	IS 807 : 2006	Design, erection and testing (structural portion) of cranes and hoists — Code of practice (*second revision*)
	IS 3177 : 2020	Electric overhead travelling crane and gantry crane for all applications — Code of practice (*third revision*)
(3)	IS 17951 : 2023	Method for determination of performance relating to safety of external building envelope impacted by wind borne debris
(4)	IS 14732 : 2000/ISO 9867 : 1984	Guidelines for the evaluation of the response of occupants of fixed structures, especially buildings and off-shore structures, to low-frequency horizontal motion (0.063 to 1 Hz)
(5)	IS 18315 : 2023	Estimation of cyclonic factor (k_4) — Guidelines
(6)	IS 1893 (Part 1) : 2016	Criteria for earthquake-resistant design of structures: Part 1 General provisions and buildings (*sixth revision*)
(7)	IS 13827 : 1993	Improving earthquake resistance of earthen buildings — Guidelines
	IS 13828 : 1993	Improving earthquake resistance of Low strength masonry buildings — Guidelines
(8)	IS 13920 : 2016	Ductile design and detailing of reinforced concrete structures subjected to seismic forces — Code of practice (*first revision*)
(9)	IS 18168 : 2023	Earthquake resistant design and detailing of steel Buildings — Code of practice
(10)	IS 3414 : 1968	Code of practice for design and installation of joints in buildings
(11)	IS 875 (Part 5) : 1987	Code of practice for design loads (Other than earthquake) for building and structures: Part 5 Special loads and combinations (*second revision*)
(12)	IS 1642 : 2013	Fire safety of buildings (general) details of construction — Code of practice (*second revision*)
(13)	IS 14680 : 2024	Landslide control measures — Guidelines (*first revision*)
	IS 17162 : 2020	Preparation of landslide risk assessment maps in mountainous terrains — Guidelines
	IS 17163 : 2020	Site specific investigation and stability analysis of landslides — Guidelines
	IS 14496	Preparation of landslide hazard zonation maps in mountainous terrains — Guidelines:
	(Part 1) : 2020	Meso-zonation
	(Part 2) : 1998	Macro-zonation
	IS 18736 : 2024	Micropiles for slope stabilization for mitigation of landslides — Guidelines
	IS 14458 (Part 1) : 1998	Retaining wall for hill area — Guidelines: Part 1 Selection of type of wall

FOREWORD

This NBCS (Part C/Sec 2) deals with the structural design aspects of foundations and mainly covers the design principles involved in different types of foundations.

This Section was published in 1970 and subsequently revised in 1983, 2005 and 2016 as a chapter of the National Building Code of India. In the first revision of 1983, design considerations in respect of shallow foundation were modified, provisions regarding pier foundation were added and provisions regarding raft foundation and pile foundation were revised and elaborated. In the second revision of 2005, design considerations in respect of shallow foundations were again modified, method for determining depth of fixity, lateral deflection and maximum moment of laterally loaded piles were modified and reference was made to ground improvement techniques.

In the third revision in 2016, the significant changes incorporated were: including the extension of the scope to cover the design of foundations on rock, modifications to definitions in line with prevailing engineering practices; addition of new terms related to pile foundations and ground improvement; inclusion of the clause on site investigation and number of modifications, such as, new methods of soil investigation; addition of depth of exploration for pile foundations; addition of new sub-clauses on vertical interval for field tests and site investigation report; inclusion of method for assessment of liquefaction potential of a site; modification of permissible differential settlements and tilt (angular distortion) for shallow foundations in soils; modification of procedures for calculation of bearing capacity, structural capacity, factor of safety, lateral load capacity, overloading, etc, in case of pile foundations; revision of design parameters with respect to adhesion factor, earth pressure coefficient, modulus of subgrade reaction, etc, for design of pile foundations to make them consistence with the outcome of modern research and construction practices; inclusion of provision for use of any established dynamic pile driving formulae, instead of recommending any specific formula, to control the pile driving at site, giving due consideration to limitations of various formulae; inclusion of a reference to spun piles, which are used in deep marshy soils where conventional pile installation beyond 50 m is difficult; elaboration of the clause on ground improvement techniques; and addition of a table on summary of soil improvement methods.

In the current revision, this publication has been renamed as National Building Construction Standards (NBCS).

As a result of technical developments in this subject, the experience gained since implementation of 2016 version of the NBCS and feedback received as well as the revision of related Indian Standards on the subject, a need was felt to revise this Section. The significant modifications made in this revision of the subsection include amongst others, the following:

a) Provisions on location and depth of investigation have been modified;

b) Provisions on various boring techniques have been updated and continuous soil samplers have been included;

c) Series of in-situ tests have been added, such as electric cone penetration test using piezocone with pore pressure measurement (CPTu), field California bearing ratio (CBR) test, cross hole seismic test (CHST), ground penetrating radar survey (GPR), spectral analysis of surface wave (SASW) and multi-channel analysis of surface wave (MASW), dilatometer test (DMT) and in-situ permeability test, etc;

d) Provisions on optical and acoustic tele-viewer methods have been added;

e) Provisions on pressuremeter test (PMT) have been detailed;

f) Detailed explanation for deep foundation has been added;

g) The provisions for the design and construction of Combined Piled Raft Foundations (CPRF) have been added. These provisions cover a composite foundation system that utilizes both raft and pile components to effectively transfer structural loads to the ground; and

h) Provision relating to geotechnical instrumentation has been introduced.

For detailed information regarding structural analysis and soil mechanics aspects of individual foundations, reference should be made to standard textbooks and available literature.

The requirements for geotechnical engineering services, including roles and responsibilities, qualifications and experience of professionals and deliverables expected from various stakeholders, are covered in IS 19235 : 2025 ‘Geotechnical engineering services — Requirements’. While the standard primarily addresses pre-construction services, it also outlines interlinked construction stage services, thereby providing comprehensive guidance for geotechnical aspects throughout the project lifecycle.

The information contained in this section is mainly based on the following Indian Standards:

IS 1080 : 1985	Code of practice for design and construction of shallow foundations in soils (other than raft, ring and shell) (*second revision*)
IS 1892 : 2021	Subsurface investigation for foundations — Code of practice (*second revision*)
IS 1904 : 2021	General requirements for design and construction of foundation in soils — Code of practice (*fourth revision*)
IS 2911	Code of practice for design and construction of pile foundations
(Part 1/Sec 1) : 2010	Concrete piles, Section 1 Driven cast *in-situ* concrete piles (*second revision*)
(Part 1/Sec 2) : 2010	Concrete piles, Section 2 Bored cast *in-situ* piles (*second revision*)
(Part 1/Sec 3) 2010	Concrete piles, Section 3 Driven precast concrete piles (*second revision*)
(Part 1/Sec 4) : 2010	Concrete piles, Section 4 Precast concrete piles in prebored holes (*first revision*)
(Part 2) : 2021	Timber piles (*second revision*)
(Part 3) : 2021	Under-reamed piles (*second revision*)
IS 2950 (Part 1) : 1981	Code of practice for design and construction of raft foundations: Part 1 Design (*second revision*)
IS 19117 : 2025	Design and construction of combined piled raft foundations — Code of practice
IS 2131 : 2025	Standard penetration test of soil — Method of test

All standards, whether given herein above or cross-referred to in the main text of this Section, are subject to the revision. The parties to agreement based on this Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

As the regulation of land development and buildings is a state subject and is dealt by the states and local bodies such as urban local bodies within their jurisdiction through building regulatory documents like building regulations, building byelaws and fire regulations, this document is voluntary in nature and is non-binding. The implementation depends on adoption by concerned parties or stipulations in a contract or by appropriate adoption by the concerned authorities.

For the purpose of deciding whether a particular requirement of this standard is complied with, the final value, observed or calculated, expressing the result of a test or analysis, shall be rounded off in accordance with IS 2 : 2022 ‘Rules for rounding off numerical values (*second revision*)’. The number of significant places retained in the rounded off value should be the same as that of the specified value in this Section.

This Page has been Intentionally left blank

Important Explanatory Note for Users of the NBCS

In any Part/Section of this NBCS, where reference is made to **'good practice'** in relation to design, constructional procedures or other related information and where reference is made to **'accepted standard'** in relation to material specification, testing, or other related information, the Indian Standards listed at the end of the Part/Section shall be used as a guide to the interpretation.

At the time of publication, the editions indicated in the standards were valid. All standards are subject to revision and parties to agreements based on any Part/Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

In the list of standards given at the end of a Part/Section, the number appearing within parentheses in the first column indicates the number of the reference of the standard in the Part/Section. For example:

a) Good practices [C-2(1)] refers to the Indian Standard(s) given at serial number (1) of the list of standards given at the end of this Part/Section, that is, IS 1892 : 2021 'Code of practice for subsurface investigation for foundation (*second revision*)', IS 2131 : 2025 'Method of standard penetration test for soils (*second revision*)', IS 2132 : 1986 'Code of practice for thin walled tube sampling of soils (*second revision*)', IS 4434 : 1978 'Code of practice for in-situ vane shear test for soils (*first revision*)', IS 4968 (Part 1) : 1976 'Method for subsurface sounding for soils: Dynamic method using 50 mm cone without bentonite slurry (*first revision*)', IS 4968 (Part 2) : 1976 'Method for subsurface sounding for soils: Dynamic method using cone and bentonite slurry (*first revision*)', IS 4968 (Part 3) : 1976 'Method for subsurface sounding for soils: Static cone penetration test (*first revision*)', IS 8763 : 1978 'Guide for undisturbed sampling of sands and sandy soils' and IS 9214 : 1979 'Method for determination of modulus of subgrade reaction (k-value) of soils in the field'.

NATIONAL BUILDING CONSTRUCTION STANDARDS

PART C STRUCTURAL DESIGN

SECTION 2 SOILS AND FOUNDATIONS

1 SCOPE

1.1 This NBCS (Part C/Section 2) covers geotechnical design (principles) of building foundations, such as shallow foundations, like, continuous strip footings, combined footings, raft foundations, deep foundations like pile foundations and other foundation systems to ensure safety and serviceability without exceeding the permissible stresses of the materials of foundations and the bearing capacity of the supporting soil/rock.

1.2 This Section also covers provisions relating to preliminary work required for construction of foundations and protection of excavation.

2 TERMINOLOGY

For the purpose of this Section, the following definitions shall apply.

2.1 General

2.1.1 *Clay* — An aggregate of microscopic and sub-microscopic particles derived from the chemical decomposition and disintegration of rock constituents. It is plastic within a moderate to wide range of water content. The particles are less than 0.002 mm in size.

2.1.2 *Clay*, *Firm* — A clay which at its natural water content can be moulded by substantial pressure with the fingers and can be excavated with a spade.

2.1.3 *Clay*, *Soft* — A clay which at its natural water content can be easily moulded with the fingers and readily excavated.

2.1.4 *Clay*, *Stiff* — A clay which at its natural water content cannot be moulded with the fingers and requires a pick or pneumatic spade for its removal.

2.1.5 *Foundation* — That part of the structure which is in direct contact with and transmits loads to the ground.

2.1.6 *Gravel* — Angular, rounded or semi-rounded particles of rock or soil of particle size between 4.75 mm and 75 mm.

2.1.7 *Peat* — A fibrous mass of organic matter in various stages of decomposition generally dark brown to black in colour and of spongy consistency.

2.1.8 *Sand* — Cohesion less aggregates of angular, sub-angular, sub-rounded, rounded, flaky or flat fragments of more or less unaltered rocks, or mineral of size between 4.75 mm and 0.075 mm IS Sieve.

2.1.9 *Sand*, *Coarse* — Sand of particle size between 2.0 mm and 4.75 mm IS Sieve.

2.1.10 *Sand*, *Fine* — Sand of particle size between 0.075 mm and 0.425 mm IS Sieve.

2.1.11 *Sand*, *Medium* — Sand of particle size between 0.425 mm and 2.0 mm IS Sieve.

2.1.12 *Silt* — Fine-grained soil or fine-grained portion of soil which exhibits a little or no plasticity and has a little or no strength when air dried. The size of particles ranges from 0.075 mm to 0.002 mm.

2.1.13 *Soft Rock* — A rocky cemented material which offers a high resistance to picking up with pick axes and sharp tools but which does not normally require blasting or chiselling for excavation.

2.1.14 *Soil*, *Black Cotton* — Inorganic clays of medium to high compressibility. They form a major soil group in India. They are predominately montmorillonitic in structure and yellowish black or blackish grey in colour. They are characterized by high shrinkage and swelling properties.

2.1.15 *Soil*, *Coarse Grained* — Soils which include the coarse and largely siliceous and unaltered products of rock weathering. They possess no plasticity and tend to lack cohesion when in dry state. In these soils, more than half the total material by weight is larger than 75-micron IS Sieve size.

2.1.16 *Soil*, *Fine Grained* — Soils consisting of the fine and altered products of rock weathering, possessing cohesion and plasticity in their natural state, the former even when dry and both even when submerged. In these soils, more than half of the material by weight is smaller than 75-micron IS Sieve size.

2.1.17 *Soil*, *Highly Organic and Other Miscellaneous Soil Materials* — Soils consisting of large percentages of fibrous organic matter, such as peat and particles of decomposed vegetation. In addition, certain soils containing shells, concretions, cinders and other non-soil materials in sufficient quantities are also grouped in this division.

2.1.18 *Total Settlement* — The total downward movement of the foundation unit under load.

2.2 Ground Improvement

2.2.1 *Ground Improvement* — Enhancement of the in-place properties of the ground by controlled application of techniques suited to subsoil conditions.

NOTE — These techniques are used to improve the load bearing capacity and settlement potential of the loose or soft soil lying close to the surface or at depths.

2.2.2 *Injection* — Introduction of a chemical/cementitious material into a soil mass by application of pressure.

2.2.3 *Liquefaction* — It is a state primarily in saturated cohesionless soils wherein the effective shear strength is reduced to negligible value for all engineering purposes, when the pore pressure approaches the total confining pressure during earthquake shaking. In this condition, the soil tends to behave like a fluid mass.

2.2.4 *Preloading* — Application of loads to achieve improvement of soil properties prior to imposition of structural loads.

2.2.5 *Soil Densification* — A technique to densify cohesionless soils by imparting shocks or vibrations.

2.2.6 *Soil Reinforcement* — Rods, strips or geosynthetics (metallic or fabric) incorporated within soil mass to impart resistance to tensile, shear and compressive forces.

2.3 Shallow Foundation

2.3.1 *Back Fill* — Materials used or reused to fill an excavation.

2.3.2 *Bearing Capacity*, *Safe* — The maximum intensity of loading that the soil will safely carry with a factor of safety against shear failure of soil irrespective of any settlement that may occur.

2.3.3 *Bearing Capacity*, *Ultimate* — The intensity of loading at the base of a foundation which would cause shear failure of the supporting soil.

2.3.4 *Bearing Pressure*, *Allowable* (*Gross or Net*) — The intensity of loading which the foundation will carry without undergoing settlement in excess of the permissible value for the structure under consideration but not exceeding safe bearing capacity.

The net allowable bearing pressure is the gross allowable bearing pressure minus the surcharge intensity.

NOTE — The concept of ‘gross’ and ‘net’ used in defining the allowable bearing pressure could also be extended to safe bearing capacity, safe bearing pressure and ultimate bearing capacity.

2.3.5 *Factor of Safety* (*with Respect to Bearing Capacity*) — A factor by which the ultimate bearing capacity (net) shall be reduced to arrive at the value of safe bearing capacity (net).

2.3.6 *Footing* — A structure constructed in brick work, masonry or concrete under the base of a wall or column for the purpose of distributing the load over a larger area.

2.3.7 *Foundation*, *Raft* — A substructure supporting an arrangement of columns or walls in a row or rows transmitting the loads to the soil by means of a continuous slab, with or without depressions or openings.

2.3.8 *Made-up Ground* — Refuse, excavated soil or rock deposited for the purpose of filling a depression or raising a site above the natural surface level of the ground.

2.3.9 *Offset* — The projection of the lower step from the vertical face of the upper step.

2.3.10 *Permanent Load* — Loads which remain on the structure for a period, or a number of periods, long enough to cause time dependent deformation/settlement of the soil.

2.3.11 *Shallow Foundation* — A foundation whose width is generally equal to or greater than its depth. The shearing resistance of the soil in the sides of the foundation is generally neglected.

2.3.12 *Spread* (*or Isolated or Pad*) *Foundation/Footing* — A foundation which transmits the load to the ground through one or more footings. A spread footing (or isolated or pad) is provided to support an individual column. A spread footing is circular, square or rectangular slab of uniform thickness. Sometimes, it is stepped or haunched to spread the load over a large area.

2.3.13 *Strip Foundation/Footing* — A type of shallow foundation which provides continuous and longitudinal bearing for loads carried by vertical elements, such as continuous wall foundation beams or the like. A strip footing is also provided for a row of columns which are so closely spaced that their spread footings overlap or nearly touch each other. A strip footing is also known as continuous footing.

2.4 Pile Foundation

2.4.1 *Allowable Load* — The load which may be applied to a pile after taking into account its ultimate load capacity, group effect, the allowable settlement, negative skin friction and other relevant loading conditions including reversal of loads, if any.

2.4.2 *Anchor Pile* — An anchor pile means a pile meant for resisting pull or uplift forces.

2.4.3 *Batter Pile* (*Raker Pile*) — The pile which is installed at an angle to the vertical using temporary casing or permanent liner.

2.4.4 *Bored Cast In-Situ Pile* — Piles formed by boring a hole in the ground by percussive or rotary method with the use of temporary/permanent casing or drilling mud and subsequently filling the hole with reinforced concrete.

2.4.5 *Bored Compaction Pile* — A bored cast *in-situ* pile with or without bulb(s) in which the reinforcement cage is driven by suitable method in the freshly filled concrete in the bore. If the pile is with bulb(s), it is known as under-reamed bored compaction pile.

2.4.6 *Bored Pile* — A pile formed with or without casing by excavating or boring a hole in the ground and subsequently filling it with plain or reinforced concrete.

2.4.7 *Cut-off Level* — It is the level where a pile is cut-off to support the pile caps or beams or any other structural components at that level.

2.4.8 *Driven Cast in-situ Pile* **—** The pile formed within the ground by driving a casing of uniform diameter, or a device to provide enlarged base and subsequently filling the hole with reinforced concrete. For displacing the subsoil the casing is driven with a plug or a shoe at the bottom. When the casing is left permanently in the ground, it is termed as cased pile and when the casing is taken out, it is termed as uncased pile. The steel casing tube is tamped during its extraction to ensure proper compaction of concrete.

2.4.9 *Efficiency of a Pile Group* — It is the ratio of the actual supporting value of a group of piles to the supporting value arrived at by multiplying the pile resistance of an isolated pile by their number in the group.

2.4.10 *Initial Load Test* — A test pile is tested to determine the load carrying capacity of the pile by loading either to its ultimate load or to twice the estimated safe load.

2.4.11 *Negative Skin Friction* — Negative skin friction is the force developed through the friction between the pile and the soil in such a direction as to increase the loading on the pile, generally due to drag of a consolidating soft layer around the pile resting on a stiffer bearing stratum such that the surrounding soil settles more than the pile.

2.4.12 *Pile Spacing* **—** The spacing of piles means the centre to centre distance between adjacent piles.

2.4.13 *Precast Concrete Piles in Prebored Holes —* A pile constructed in reinforced concrete in a casting yard and subsequently lowered into prebored holes and the annular space around the pile grouted.

2.4.14 *Precast Driven Pile* — The pile constructed in concrete in a casting yard and subsequently driven into the ground when it has attained sufficient strength.

2.4.15 *Routine Test* — Test carried out on a working pile with a view to check whether pile is capable of taking the working load assigned to it without exceeding permissible settlement.

2.4.16 *Safe Load* **—** It is the load derived by applying a factor of safety on the ultimate load capacity of the pile/pile group or as determined from load test.

2.4.17 *Ultimate Load Capacity* — The maximum load which a pile can carry before failure, that is, when the founding strata fails by shear as evidenced from the load settlement curve or the pile fails as a structural member.

2.4.18 *Under-Reamed Pile* — A bored cast *in-situ* or bored compaction concrete pile with enlarged bulb(s) made by either cutting or scooping out the soil or by any other suitable process.

An under-reamed pile having more than one bulb is termed as multi under-reamed piles. The piles having two bulbs may be called double under-reamed piles.

2.4.19 *Working Load* — The load assigned to a pile as per design.

2.4.20 *Working Pile* — A pile forming part of the foundation system of a given structure.

2.5 Combined Piled-Raft Foundations

2.5.1 *Allowable Load* **—** The load which can be applied on the combined pile-raft foundation system by taking into account the load capacities of piles and raft, soil-pile-raft interaction effects and allowable displacement from serviceability criteria, negative skin friction on pile and other relevant loading types including reversal of loads, if any. In other words, it is the load at which the allowable settlement reduction ratio considering serviceability is achieved.

2.5.2 *Angular Distortion* ($\boldsymbol{\theta}$) **—** Vertical distance after deformation due to applied load between the points of maximum and minimum settlement divided by the horizontal distance between the two points (*see* Fig. 1).

2.5.3 *Combined Piled Raft Foundation* **—** A pile group in which the raft connecting all the pile heads positively contributes to the overall foundation behaviour. The presence of raft is recognized and its contribution in sharing the load with the pile group is taken into account. This composite foundation which combines load carrying capabilities of raft and pile foundations together, considers four interactions, namely, pile-pile interaction, pile-soil interaction, pile-raft interaction and raft-soil interaction [*see* Fig. 2(A)].

2.5.3.1 *Large CPRF* **—** CPRF in which the ratio of raft width (Br) to pile length (Lp) is greater than 1, that is, $\frac{B_r}{L_p} > 1$.

2.5.3.2 *Small CPRF* **—** CPRF in which the ratio of raft width (Br) to pile length (Lp) is less than or equal to 1, that is, $\frac{B_r}{L_p} \leq 1$.

2.5.4 *Cut-off Level* **—** The level where a pile is cut-off in order to make structural connection to the pile caps or beams or raft or any other structural component at that level.

2.5.5 *Design Load* — The loads (compression, tension, lateral, moment or any combination thereof) considered to act on the CPRF during the life of the structure satisfying provisions mentioned in other relevant Indian Standards.

2.5.6 *Design Stress* — The stress (compressive, tensile or combination) imposed on the CPRF by the design load and calculated in accordance with engineering practice.

2.5.7 *Differential Settlement of CPRF* (*Spr*, *Diff*) — The difference between the maximum and the minimum settlement, across any section of the CPRF (*see* Fig. 1).

2.5.8 *Limiting Capacity* — The vertical load at which for a CPRF, bearing capacity failure occurs due to exceedance of the combined capacity of raft resistance and that of piles in terms of shaft resistance and end bearing resistance. The assessed value of the total resistance Rtot,k(s) of the CPRF depends on the settlements of the foundation and consists of the sum of the assessed pile resistances $\Sigma Rpile{,}k{,}j$ (s) and the assessed raft resistance, Rraft,k (s) [*see* Fig. 2(A)]. The assessed raft resistance results from the integration of the settlement dependent contact pressure, $\sigma(s,\, x,\, y)$ in the ground plan area of the raft and can be expressed as, $Rraft{,}k(s) = \iint \sigma(s,\, x,\, y)dxdy$. Similarly, due considerations for horizontal load capacity and moment capacity should be considered for the CPRF system.

2.5.9 *Load Eccentricity* (*eL or eB*) — Distance between the point of application of applied resultant load and the centre of gravity of the pile-raft system along length and width, respectively (*see* Fig. 1).

2.5.10 *Maximum CPRF Settlement* (*Spr*, *Max*) — The maximum value of settlement occurred at a particular point of the CPRF system (*see* Fig. 1).

2.5.11 *Pile-Pile Interaction* — The result of pile group effect, defined as the changes in the load-displacement response of a pile group and single piles due to superimposition of stress and displacement field of a single pile in a group [*see* Fig. 2(A)].

2.5.12 *Pile-Raft Interaction* — The changes in the load-displacement response of pile group when the raft is being rested to the soil surface [*see* Fig. 2(A)].

2.5.13 *Pile-Raft Coefficient or Load Sharing Ratio* (α_{CPRF}) — The ratio between the sum of the pile resistances and the value of the total resistance.

NOTE — $\alpha_{\mathrm{CPRF}} = \frac{R_{\mathrm{piles}}}{R_{\mathrm{total}}}$, in which R_{piles} is the resistance provided by piles and R_{total} is the total resistance provided by the CPRF system under vertical load as shown in Fig. 2(B). Whenever, α_{CPRF} is equal to 1, all the vertical loads are taken up by the pile component which essentially makes the system to behave as a pile group foundation. Whereas, α_{CPRF} equals to zero indicates that the vertical loads are borne by raft component, hence, the foundation behaviour will be like spread raft foundation. To utilize both the foundation components effectively, the value of α_{CPRF} should be chosen carefully and the standard is not valid for $\alpha_{\mathrm{CPRF}} \geq 0.9$.

2.5.14 *Pile-Enhanced Raft* — CPRF in which the piles are designed to mobilize their total ultimate capacity and the raft carries majority of the design load [*see* Fig. 3(A)].

2.5.15 *Raft-Pile Interaction* — The modification in the load carrying mechanism of the raft when piles are introduced beneath [*see* Fig. 2(A)]

2.5.16 *Raft-Enhanced Pile* — CPRFs in which both the piles and raft work within a pseudo-elastic range of behaviour. The pile group capacity is not fully mobilized at working load and the pile group carries majority of the design load [*see* Fig. 3(B)].

2.5.17 *Settlement Reduction Ratio* (*SRR*) — The ratio of the difference of settlement of the unpiled raft under the given loading, Sr and the settlement of the piled raft under the same loading considered in the case of the unpiled raft, S_{pr} to the settlement of the unpiled raft, that is, under any given loading conditions, SRR $= \frac{(S_{\mathrm{r}} - S_{\mathrm{pr}})}{S_{\mathrm{r}}}$.

3 SITE INVESTIGATION

3.1 General

3.1.1 Site investigation is essential in determining the physical, chemical and engineering properties of subsoil to arrive at the required foundation system. However, in areas which have already been developed, information may be obtained regarding the existing local knowledge, records of trial pits, boreholes, etc, in the vicinity and the behaviour of the existing structures, particularly those of a similar nature to those proposed. This information may be made use of for design of foundation of lightly loaded structures of not more than two storeys and also for deciding the scope of further investigation for other structures.

3.1.2 If the existing information is not sufficient or is inconclusive, the proposed site should be explored in detail as per good practice [C-2(1)], so as to obtain a knowledge of the type, uniformity, consistency, thickness, sequence and dip of the strata, hydrology of the area and also the engineering properties. In the case of lightly loaded structures of not more than two storeys the tests required to obtain the above information are optional, mainly depending on site conditions.

3.1.3 *Geotechnical Engineering Services*

Geotechnical engineering services encompass the entire process of understanding ground conditions and providing reliable inputs for civil engineering works. They include site reconnaissance, planning and execution of field and laboratory investigations and interpretation of soil and rock behaviour for safe and economical design. The services also define the roles of the Appointing Authority (AA), Geotechnical Consultant (GC) and Geotechnical Investigation Agency (GIA), along with structured models of appointment — Model 1, where GC and GIA are appointed separately and Model 2, where GC is appointed and may additionally act as GIA. These provisions cover both pre-construction and interlinked construction stage activities, ensuring that the design and execution of works are based on sound geotechnical data and professional judgement.

A clear distinction is laid down between geotechnical factual reports (GFR), which document the results of investigations and geotechnical interpretive reports (GIR), which provide engineering analysis and design recommendations. The framework specifies minimum qualifications and experience requirements for team leaders to promote competence and accountability, while also incorporating provisions on safety, quality assurance, quality control and declarations against conflict of interest. Together, these measures strengthen transparency, consistency and technical integrity in geotechnical practice. Reference may be made to the good practice [C-2(2)] for more detail.

3.2 Stages of Subsurface Investigation

3.2.1 The stages of subsurface investigation are:

a) site reconnaissance;

b) preliminary investigation;

c) detailed investigation;

d) construction stage investigation; and

e) post-construction stage investigation.

3.2.2 *Site Reconnaissance*

3.2.2.1 Site reconnaissance would help in deciding future programme of field investigations, that is, to assess the need for preliminary and/or detailed investigations.

This would also help in determining scope of work, methods of exploration to be adopted, *in-situ* tests to be carried out and administrative arrangements required for the investigation. Where detailed information on the geotechnical conditions is not available, an inspection of site and study of topographical features are helpful in getting information about soil, rock and ground-water conditions. Site reconnaissance includes a study of local topography, excavations, ravines, quarries, escarpments; evidence of erosion or landslides, behaviour of existing structures at or near the site; water level in streams, water courses and wells; flood marks; nature of vegetation; drainage pattern, location of seeps, springs and swamps, evidence of expansive soils. Information on some of these may be obtained from topographical maps, geological maps, pedological and soil survey maps, vicinity maps, metrological data and digitized images.

3.2.2.2 Data regarding removal of overburden by excavation, erosion or landslides should be obtained. This gives an idea of the amount of pre-consolidation the soil strata have undergone. Similarly, data regarding recent fills is also important to study the consolidation characteristics of the fill as well as the original strata.

3.2.2.3 The type of flora affords at times some indication of the nature of the soil. The extent of swamp and superficial deposits and peats will usually be obvious. In general, such indications, while worth noting, require to be confirmed by actual exploration.

3.2.2.4 *Ground-water conditions*

The ground-water level fluctuates and will depend upon the permeability of the strata and the head causing the water to flow. The water level in streams and water courses, if any, in the neighbourhood, should be noted, but it may be misleading to take this as an indication of the depth of the water table in the ground. Wells at the site or in the vicinity give useful indications of the ground-water conditions. Flood marks of rivers may indicate former highest water levels. Tidal fluctuations may be of importance. There is also a possibility of there being several water tables at different levels, separated by impermeable strata and some of this water may be subject to artesian head. It is also important to collect water samples to check its suitability for construction purpose and any treatment of foundation required for corrosion protection.

3.2.2.5 *Enquiries regarding earlier use of the site*

In certain cases, the earlier uses of the site may have a very important bearing on proposed new works. This is particularly so in areas, where there have been underground workings, such as worked-out ballast pits, quarries, old brick fields, coal mines and mineral workings. Enquiries should be made regarding the location of shafts and workings, particularly shallow ones, where there may be danger of collapse, if heavy new structures are superimposed.

The possibility of damage to sewers, conduits and drainage systems by subsidence should also be investigated.

3.2.3 *Preliminary Investigation*

The purpose of preliminary investigation is to assess the feasibility of a project. The preliminary investigation includes determination of approximate depth, thickness, extent and composition of sub-strata, ground water table and also to obtain approximate information regarding strength and compressibility of the various strata. The preliminary investigation comprises boreholes with standard penetration test (SPT), collection of disturbed samples (DS), undisturbed samples (UDS), dynamic cone penetration test (DCPT), trial pits and laboratory testing. Geophysical investigation may also be carried out during the preliminary investigation to establish the sequence of layers, their approximate properties, depth of bedrock, etc.

3.2.4 *Detailed Investigation*

Planning of detailed investigation is generally based on the information obtained in the preliminary investigation. The objective is to find the sequence of various layers, thickness of the layers, ground water table and detailed engineering properties of each layer. Detailed investigation involves *in-situ* (field) testing and laboratory testing. The *in-situ* tests are described in 3.4. Laboratory testing on soil/rock/water samples collected from the site is carried out to determine the index, physical, engineering and chemical properties as given in 3.5.7. The type and number of tests shall depend upon the nature of the project, geology of the area and site conditions.

3.2.5 *Construction Stage Investigation*

During construction, there may be a requirement of additional investigation to overcome the difficulties/modifying the foundation system due to change in subsoil/ground water conditions. The type of test required shall be selected from those specified under detailed investigation.

3.2.6 *Post-construction Stage Investigation*

At times, in order to study the behaviour/strengthening of substructure/foundation, investigation may be required.

3.3 Subsurface Exploration

The subsurface exploration includes the following:

- a) Geophysical investigation;
- b) Trial pits;
- c) Subsurface soundings;
- d) Boring in soil;
- e) Core drilling in rock; and
- f) Location and depth of investigation.

3.3.1 *Geophysical Investigation*

The geophysical investigation includes measurement of physical properties of the ground based on which the type of strata and depth of strata can be approximately evaluated. These tests provide a quick means of getting useful information about the stratification and underground utilities. This will enable to plan the depth/extent of the *in-situ* tests and type of test to be carried out *in-situ* and in the laboratory. The method provides only approximate parameters about the strata which need to be confirmed by conducting detailed investigation. These methods may be employed to get preliminary information on stratigraphy or complement a rationalized boring programme by correlation of stratigraphy between widely spaced boreholes. Commonly adopted geophysical tests are given in Table 1.

Table 1 Geophysical Tests

(*Clause* 3.3.1)

Sl No. (1)	Type of Test (2)	Property Measured (3)
i)	Electrical resistivity test (ERT)	Electrical resistivity
ii)	Seismic refraction test (SRT)	Primary wave velocity
iii)	Cross hole seismic test (CHST) and down hole seismic test (DHST)	Shear wave velocity
iv)	Spectral analysis of surface wave (SASW) and multi-channel analysis of surface wave (MASW)	Primary/Shear wave velocity
v)	Ground penetrating radar survey (GPR survey)	Electromagnetic intensity (resistivity)
vi)	Thermal resistivity test	Thermal conductivity

3.3.2 *Trial Pit*

This method consists of excavating a pit at the site and thereby exposing the strata. This enables visual inspection of the strata, collection of disturbed/undisturbed samples and carrying out *in-situ* tests. Generally, trial pits are excavated up to 4 m depth below the ground level.

Minimum dimension of the pit shall be such that there is an adequate working space for excavation and carrying out sampling/testing. Generally, the pits have planned dimensions varying from 1 m × 1 m up to 3 m × 3 m depending on the depth required.

After the pit is excavated, the details of the strata shall be recorded with the description of each layer with thickness and ground water table, if any. After collecting the samples/in-situ testing, the pit shall be backfilled with the same excavated material. Arrangement shall be made for dewatering below ground water table. Precautions shall be taken to prevent surface water draining into the trial pit.

3.3.3 *Subsurface Soundings*

Subsurface soundings provide quick means to get continuous resistance against penetration indicating compactness of the strata. The following sounding tests are generally carried out:

a) Dynamic cone penetration test;

b) Static cone penetration test; and

c) Static cone penetration test using piezocone with pore water pressure measurement.

The limitation of soundings is that samples cannot be collected. In addition, strata having stones, gravels, boulders, etc and stiff formations cannot be penetrated by sounding device.

3.3.4 *Boring in Soil*

Various techniques are available for boring in soil depending on the substrata and depth of investigation. Commonly used boring methods are given below and described in **3.3.4.1** to **3.3.4.4**.

a) Auger boring;

b) Shell and auger boring;

c) Rotary boring; and

d) Percussion drilling.

In general, the diameter of the borehole is about 100 mm to 150 mm. In boreholes, in-situ testing like standard penetration test along with collection of disturbed and undisturbed samples at regular depth intervals and at change of strata is carried out. Other *in-situ* tests may also be carried out in the boreholes as per requirements.

In order to prevent caving in of soil during boring, stabilizing fluid like bentonite slurry/temporary steel casing or combination of both should be used.

The bottom of the borehole shall be cleaned prior to sampling/testing at different levels.

3.3.4.1 *Auger boring*

An auger is either power or hand operated with periodic removal of cuttings. The bore profile is prepared based on physical observation of the cut material removed from auger.

The process is slow in case of manual operation. Hand operated auger is generally used for boring up to a depth of 6 m. Casing is not used in this method. The method is convenient considering ease of mobilization. The auger is used in soil where borehole stands unsupported. Auger is penetrated into the ground for a depth of about 300 mm to 600 mm and the auger is withdrawn for removing the cuttings. The auger is then reintroduced to extend the borehole.

3.3.4.2 *Shell and auger boring*

Shell and auger boring is adopted for deep boreholes. The equipment consists of auger and a shell (bailer) for boring, connected with steel wire ropes/drilling rods which are lowered/raised with the help of tripod and mechanical winch. The casing is lowered in the borehole by rotating/pushing to the required depth.

The auger is generally used up to the ground water table level followed by shell.

The shell is raised/lowered repeatedly to cut the soil at the bottom and the cut material collected in the shell is removed. In stiff cohesive soil, it may be necessary to soak the borehole while boring above the ground water table. Where ground water is encountered, the water level in the borehole shall always be maintained at or above the water table.

The method is efficient to drill in hard strata but may disturb the soil at the bottom of the borehole. The method should be adopted with caution to minimize disturbances in the soil, prior to sampling/testing.

3.3.4.3 *Percussion drilling*

This method should only be used for drilling boreholes in bouldery and gravelly strata where other boring methods become ineffective.

In this method, the formation is pulverized/broken by repeated blows using a bit or a chisel. Water should be added at the time of boring and the cuttings are bailed out at intervals. The bit/chisel is suspended by a cable or rods from a hoist.

As this method involves repeated dropping of a heavy chisel and can disturb the strata considerably, it is preferable that at least 0.5 m above the level of sampling/testing, the use of percussion method shall be discontinued and the borehole advanced/cleaned with shell or any other suitable method till the sampling depth has reached.

3.3.4.4 *Rotary boring*

In this method, boring is advanced by the cutting action of a rotating bit which should be kept in firm contact with the bottom of the hole. The bit is connected at the end of hollow, jointed drill rods which are rotated by a suitable chuck. Water/stabilizing fluid like bentonite slurry is pumped continuously down the hollow drill rods and the fluid returns to the surface through the annular space between the rods and the side of the hole and the casing may not be generally required. This method can be used in all type of strata.

3.3.5 *Core Drilling in Rock*

Core drilling in rock shall be carried out with rotary hydraulic rig using diamond-tipped bit (*see* Note) as per good practice [C-2(3)]. The core drilling equipment shall conform to accepted standard [C-2(4)]. Drilling shall be carried out with NX/HX size diamond-tipped drill bits or impregnated diamond bit depending on the type of rock formation. Double tube core barrel with core lifter shall be used. The diamond bit is attached to double tube core barrel with reaming shell. The bit cuts an annular groove into the formation and the inner core formed by the groove enters into the inner barrel as a core sample. The circulating fluid is injected through the annular gap between the outer barrel and inner barrel and hence the fluid does not come in contact with the core received in the barrel. This prevents damage to the core by washing out of the loose particles in the joints (if any) and improves both core recovery and rock quality designation (RQD). After advancing the core barrel, the barrel is withdrawn, the rock cores are removed by detaching the core cutter, reassembled and introduced back in the borehole for further coring. Indexing and storage of drill cores shall be in accordance with good practice [C-2(5)].

NOTE — Tungsten carbide bit may be used for rocks like, shale, siltstone and claystone.

The drilling rig shall have necessary facilities to regulate the spindle speed, bit pressure and water pressure during core drilling to get good core recovery.

The rotational speed of the bit (spindle speed), the amount of downward pressure applied on the bit (bit pressure) and water pressure shall be suitably adjusted and properly monitored so that the core is collected with least disturbance and avoid shearing of the core from its base.

Drilling run should be 0.75 m in length. This can be increased up to 1.5 m run in case core recovery is more than 50 percent in two successive 0.75 m drill runs. If the core recovery is nil, then SPT shall be performed before commencing the next drill run.

If at any time a blocking of the bit or grinding of the core is indicated, the core barrel shall be immediately withdrawn from the borehole regardless of the length of drill run completed.

3.3.6 *Location and Depth of Investigation*

3.3.6.1 The location and depth of investigation points shall depend upon the type of structure/building considering variation in substrata based on the preliminary subsurface investigation or available geotechnical data in an already developed site. The investigation points should be arranged in such a pattern that the stratification can be assessed across the site. The guidelines as specified in **3.3.6.2** and **3.3.6.3** may be adopted for deciding the location and depth of boreholes/trial pits and other *in-situ* tests.

3.3.6.2 *Disposition of Boreholes/Trial Pits*

The guidelines for disposition of boreholes/trial pits are given in Table 2. In case significant variation in stratification is observed, additional boreholes/tests, as required may be carried out.

Table 2 Disposition of Borehole/Trial Pit

(*Clause* 3.3.6.2)

Sl No. (1)	**Type of Structure/Buildings** (2)	**Location of Borehole/Trial Pit** (3)
i)	For lightly loaded residential building (such as single/double storeyed building)	At least one borehole/trial pit in the centre of the building (*see* Note)
ii)	For building(s) in a site covering an area of about 0.4 hectares	At least one borehole in each corner and one in the centre
iii)	a) For structure/building having any of the plan dimensions exceeding 50 m b) For multiple buildings in a site covering an area of more than 0.4 hectares c) For multistoried buildings and structure of height less than and equal to 50 m	Boreholes in a grid pattern with points at not more than 50 m distance, subject to a minimum of two boreholes. Boreholes should cover built-up areas.
iv)	For multistoried buildings and structure of height more than 50 m	Minimum three boreholes at each building/structure
v)	Linear structures (roads, railways, embankments, pipelines, boundary walls, tunnels, retaining walls, transmission lines, etc)	Boreholes at a spacing of 50 m to 500 m. In highly erratic substrata, spacing may be suitably reduced. In uniform substrata, the spacing may be suitably increased.
vi)	Solar power plant	One borehole for every 2 to 5 hectares subject to a minimum of 5 boreholes per site

NOTE — Boreholes are preferred over trial pits.

3.3.6.3 *Depth of Investigation*

3.3.6.3.1 The depth of investigation shall be adequate enough to provide necessary data for estimating safe bearing capacity and settlement. In general, the investigation shall be carried out to a minimum depth to which the increase in stress level due to the foundation load is lesser than 10 percent of the in-situ stress level.

The depth of investigation also depends on the risk induced by the presence of weaker formations below the influence zone to be stressed due to the proposed construction.

3.3.6.3.2 The following guidelines may be followed for adopting the depth of investigation:

a) *Shallow foundation* (*other than raft foundations*) *in soil* —The depth of investigation shall be up to 2 to 3 times the estimated width of the largest foundation below the expected founding level;

b) *Raft foundation* (*minimum foundation width equal to 6 m for the purpose of investigation*) *in soil* — In case of raft foundation, the depth of investigation shall be up to 1.0 to 2.0 times the width of the raft foundation below the expected founding level;

c) *Pile foundation in soil* — The depth of investigation shall be sufficiently below the expected founding level of piles but this should not be less than 5 m or 5 times the diameter of piles, whichever is more beyond the estimated pile termination level;

d) *Embankments* — The depth of investigation shall be 1.0 to 2.0 times the height of the embankment;

e) *Well foundation in soil* — The depth of investigation in the case of well foundation shall be 1.5 to 2.0 times the width/diameter of the well from the estimated termination level of the well; and

f) *Penetration into rock* — In case rock formation is encountered prior to the termination depth of boreholes as stipulated in (a) to (e) above, the boreholes may be extended by minimum 5 m in rock strata depending upon rock characteristics and project requirements.

NOTE — The depth of investigation may be suitably arrived as per the specific requirements for any other foundation/substructure.

3.3.6.4 *Other in-situ tests*

The location and depth of investigation for other *in-situ* tests shall be as per the requirements.

3.4 *In-Situ* Testing

In-situ tests provide information about the strength and deformability characteristics of the strata. Following are the *in-situ* tests which may be conducted depending on the nature of the strata and project requirements:

a) Standard penetration test (SPT);
b) Vane shear test (VST);
c) Pressuremeter test (PMT);
d) Plate load test (PLT);
e) Cyclic plate load test (CPLT);
f) Block vibration test (BVT);
g) Dynamic cone penetration test (DCPT);
h) Static cone penetration test (SCPT);
j) Piezocone with pore pressure measurement (CPTu);
k) Flat dilatometer test (DMT);
m) Electrical resistivity test (ERT);
n) Seismic refraction test (SRT);
p) Down hole, up-hole and cross hole seismic test (CHST);
q) Spectral analysis of surface wave (SASW) and multi-channel analysis of surface wave (MASW) test;
r) Ground penetrating radar (GPR) survey;
s) Thermal resistivity test;
t) *In-situ* permeability test;
u) Modulus of subgrade reaction;
v) Field california bearing ratio test (CBR); and
w) Optical and acoustic tele-viewer methods.

3.4.1 *Standard Penetration Test*

Standard penetration test (SPT) shall be conducted in all type of soil deposits to determine the resistance of soil at any depth in a bore hole and to recover disturbed soil sample for laboratory testing/identification purpose.

The basis of the test consists of driving a split spoon sampler by dropping a hammer of 63.50 kg ± 0.50 kg mass onto an anvil or drive head from a height of 750 mm ± 10 mm. The number of blows necessary to achieve 300 mm penetration of the sampler after the seating penetration of 150 mm is the penetration resistance. The test shall be conducted in accordance to good practice [C-2(6)]. In this test, the drive weight assemblies namely:

a) safety hammer with inner guide rod assembly and concealed anvil over which the hammer strikes;

b) do-nut hammer or safety hammer equipped with auto trip mechanism; and

c) automatic hammer system with the housing are preferred for consistent transfer of energy in each strike.

Hammer drop system used for lifting and dropping during the test shall be either mechanical auto-trip system or fully automated system in order to minimize human error. Rope and cat-head mechanism shall be used only when the other systems namely. mechanical auto trip system/fully automated system are not practicable. The depth interval between the bottom of the test and next undisturbed sampling/testing shall not be less than 500 mm.

3.4.2 *Vane Shear Test*

Field vane shear test shall be performed inside the borehole to determine the shear strength of cohesive soils, especially in soft clays which are highly susceptible to sampling disturbance, in accordance with good practice [C-2(7)].

3.4.3 *Pressuremeter Test*

The test is carried out to determine the *in-situ* stress-strain characteristics of the substrata. The test involves positioning of a radially expandable probe at the desired depth in a borehole and applying increments of pressure to inflate the probe thus applying increasing radial stresses on the substrata in the walls of the borehole and measuring the volumetric deformations at different pressure increments. Applied pressure *versus* volumetric deformation is plotted and analyzed. Further details regarding the test are given in good practice [C-2(8)].

3.4.4 *Plate Load Test*

Plate load test shall be conducted to determine the load/settlement characteristics of the substrata. The specifications for the equipment and accessories required for conducting the test, the test procedure, field observations and reporting of results shall conform to accepted standard [C-2(9)].

3.4.4.1 *Test for determination of modulus of subgrade reaction*

Modulus of subgrade reaction shall be determined in accordance with accepted standard [C-2(10)].

3.4.5 *Cyclic Plate Load Test*

This test shall be carried out to determine the dynamic soil properties required for the analysis of foundation subjected to dynamic loads. This test shall be conducted on similar lines as the ordinary plate load test. In addition, unloading shall also be done before each stage of loading. Test set up, load increment, maximum load intensity, recording of field data, etc shall be as per accepted standards [C-2(11)].

After each stage of loading, the load shall be removed in a minimum of two stages. After each stage of reduction of load, dial gauge readings and settlements shall be taken for at least one hour until the readings stabilize. There after the next loading stage shall commence. Analysis of test data shall be reported in accordance with accepted standard [C-2(12)].

3.4.6 *Block Vibration Test*

This test shall be carried out in accordance with accepted standard [C-2(12)] to determine the dynamic soil properties required for the analysis of foundation subjected to dynamic loads.

A test pit of suitable size depending upon size of block should be made. The size of the pit may be 3 m × 6 m at the bottom and a depth preferably equal to proposed depth of foundation. The test should be conducted above the ground water table. In case of rock, the test may be performed on the surface of rock bed itself. The bottom of the pit should be levelled. Side slopes of the pit should be stable. Analysis of test data shall be reported as per accepted standard [C-2(12)].

3.4.7 *Dynamic Cone Penetration Test* (*DCPT*)

Dynamic cone penetration test is a method of sub surface sounding, wherein a continuous record of soil resistance is obtained from of the ground to the depth below by driving a cone. Dynamic cone penetration test shall be conducted either as per accepted standard [C-2(13)] or as per [C-2(14)], as required. The test shall be conducted up to the required depth; however, in order to avoid damage to the equipment, driving may be stopped when the number of blows exceeds 35 mm for 100 mm penetration when the cone is driven dry {*see* accepted standard [C-2(13)]} and 20 mm for 100 mm penetration when the cone is penetrated by circulating slurry {*see* accepted standard [C-2(14)]}. The specification for the equipment and accessories required for performing this test, procedure, field observations and reporting of results shall be in accordance with accepted standard [C-2(13)] or as per [C-2(14)], as applicable. For gravelly deposits (gravel size 100 mm to 120 mm), DCPT may be conducted as per good practice [C-2(15)].

3.4.8 *Static Cone Penetration Test* (*SCPT*)

Static cone penetration test is conducted to record the continuous *in-situ* penetration resistance of soils below the ground level. The specification for the equipment and accessories required for performing the test procedure, field observations and reporting of results shall be in accordance with accepted standard [C-2(16)].

3.4.9 *Static Cone Penetration Test using Piezocone with Pore Water Pressure Measurement* (*CPTu*)

The test is used to record the continuous *in-situ* penetration resistance, frictional resistance along with pore water pressure during penetration at the level of the base of the cone. For CPTu, all measurements shall be made by sensors contained in penetrometer.

The cone shall be pushed into the soil at a constant rate of penetration.

Test performed using this test method provide a detailed record of cone penetration which is useful for evaluation of site stratigraphy, homogeneity, voids or cavities and other discontinuities. The use of friction sleeve and porewater pressure element can provide an estimate of preliminary soil classification and correlations with engineering properties of soils.

NOTE — The test procedure, field observation and reporting of result may be referred from international standards.

3.4.10 *Flat Dilatometer Test* (*DMT*)

The test is used to determine *in-situ* strength and deformation properties of soils. The test consists of inserting a blade-shaped steel probe vertically into the soil with a thin expandable circular steel membrane mounted flush on one face and determining, at selected depths or in a semi-continuous manner, the contact pressure exerted by the soil against the membrane when the membrane is flush with the blade and subsequently the pressure exerted when the central displacement of the membrane reaches 1.10 mm. Further details regarding the test are given in good practice [C-2(8)].

NOTE — The test procedure, field observation and reporting of results may be referred from international standards.

3.4.11 *Electrical Resistivity Test*

This test is carried out to assess the substrata profiles (that is, soil and rock profiles) over large areas at a relatively lower cost and can thus supplement the information obtained from detailed site investigations.

This test involves placing four electrodes in line along the ground surface and passing an alternating current through the outer two current electrodes and measuring the resulting potential drop between the two inner potential electrodes. From the resistance, calculated as the ratio of the potential drop to the current applied, the apparent resistivity of the substrata (that is, soil or rock strata) is determined by multiplying with applicable factors which are dependent on the geometry and spacings of the four electrodes. The electrode spacings are varied and the apparent resistivity of the substrata is determined for various electrode spacings.

Detailed analysis/interpretation of the plot of apparent resistivity *versus* electrode spacings is carried out to assess the number and type of substrata and their thicknesses.

The equipment and accessories required for carrying out the test, the test procedure, recording of observations, presentation and analysis of results shall be in accordance with good practice [C-2(17)].

Electrical resistivity tests are also carried out to determine the earth resistivity of the substrata for use in the design of earthing systems. The equipment and accessories required for carrying out the test for earth resistivity determination, the test procedure, recording of observations, presentation and analysis of results shall be in accordance with good practice [C-2(18)].

3.4.12 *Seismic Refraction Test*

This test is carried out to assess the substrata profiles (that is, soil and rock profiles) over large areas to supplement the information obtained from detailed site investigations.

This test involves the generation of seismic waves in the ground using a suitable seismic source and recording these seismic waves through geophones (that is, instruments which convert ground vibrations to electrical signals) located in a line along the ground surface at regular distance intervals. From the recorded waveforms, the arrival times of the seismic waves at different geophone locations are determined and a plot is then drawn of the geophone distances *versus* the corresponding arrival times. The refraction/reflection of the seismic waves at the interfaces of the various substrata leads to variations in the arrival times of the seismic waves at larger distances from the seismic source. The slopes of the lines connecting the data points on such a plot give the seismic wave velocities of the various substrata. The thicknesses of the various substrata so identified are determined by detailed analysis/interpretation of the plot which are based on the principles of refraction/reflection of the seismic waves.

The equipment and accessories required for carrying out the test, the test procedure, recording of observations, presentation and analysis of results shall be in accordance with good practice [C-2(19)].

3.4.13 *Downhole*, *Uphole and Crosshole Seismic Tests*

These tests are carried out to determine the seismic wave velocity profiles with depth and therefrom the profiles of dynamic modulus of rigidity (that is, shear modulus) and dynamic Young’s modulus (that is, elastic modulus) with depth.

In the downhole seismic test, seismic waves are generated in the ground by a suitable seismic source at the ground surface near a borehole and the seismic waves so generated are recorded using geophones located at different depths within the borehole. On the other hand, in the uphole seismic test, seismic waves are generated at different depths within a borehole by a suitable seismic source and the seismic waves so generated are recorded using a geophone located at the ground surface near the borehole.

In the crosshole seismic test, seismic waves are generated at different depths within a borehole termed the source borehole, using a suitable seismic source and the seismic waves so generated are recorded using geophones installed at the corresponding depths in one or two other boreholes termed the receiver boreholes, located in a straight line with the source borehole at predefined borehole spacings.

In these tests, from the recorded waveforms, the seismic wave velocities are determined and therefrom the dynamic shear and elastic moduli are determined.

The equipment and accessories required for carrying out the downhole or uphole seismic test, the test procedure, recording of observations, presentation and analysis of results shall be in accordance with good practice [C-2(20)].

The equipment and accessories required for carrying out the crosshole seismic test, the test procedure, recording of observations, presentation and analysis of results shall be in accordance with good practice [C-2(21)].

3.4.14 *Spectral Analysis of Surface Wave* (*SASW*) *and Multi-Channel Analysis of Surface Wave* (*MASW*) *Test*

The tests are used for evaluation of substrata properties based on the generation of wave propagation phenomena like reflection, refraction and dispersion. Compression and surface wave velocities are measured. Further details regarding the test are given in the good practice [C-2(8)].

NOTE — The test procedure, field observation and reporting of results may be referred from international standards.

P-wave and S-wave velocities as obtained from above tests can also be used to get seismic tomography.

3.4.15 *Ground Penetrating Radar Survey*

Ground penetrating radar (GPR) is a tool to assess the presence of soil/rock strata and to identify presence of buried objects such as pipeline, conduit, concrete, etc. This works on the principle of reflection of the electromagnetic waves at the interface of two different materials. The depth of penetration below the ground surface can be increased by reducing the frequency.

3.4.16 *Thermal Resistivity Test*

Thermal resistivity test is conducted to determine the thermal conductivity of soil and soft rock in field using thermal needle probe procedure. Further details regarding the test are given in good practice [C-2(8)].

NOTE — The test procedure, field observation and reporting of results may be referred from international standards.

3.4.17 *In-situ Permeability Test (in Soil)*

In-situ permeability test is conducted to determine the water percolation capacity of the sub strata. This test is performed inside a borehole/trial pit at specified depths. The type of test shall be either pump-in or pump-out test depending on the subsoil and ground water conditions. Pump-in test is suitable for sub-strata with or without ground water; wherein pump-out test is conducted for sub-strata with ground water.

3.4.17.1 *Pump-in test*

Pump-in test is conducted in a borehole/trial pit by allowing water to percolate into the soil.

a) *Constant head method* (*in borehole*) — This test is preferred for soils with high permeability. The specification for the equipment and the procedure of testing shall be in accordance with good practice [C-2(22)];

b) *Falling head method* (*in borehole*) — This method is preferred for soils with low permeability. The specification for the equipment and the procedure of testing shall be in accordance with good practice [C-2(22)]; and

c) *Percolation test* (*in trial pit*) — Percolation test in trial pit shall be conducted as per good practice [C-2(23)].

3.4.17.2 *Pump-out test*

Pump-out test is conducted in a borehole by pumping out of water from sub-soil. The specification for the equipment and procedure for testing shall be in accordance with good practice [C-2(22)].

3.4.18 *In-situ Permeability Test* (*in Rock*)

In-situ permeability test is conducted inside the drilled hole by pumping in water under pressure to determine the percolation capacity of the rock stratum. The test may be conducted by single packer method or by double packer method. The specification for the equipment and the procedure of testing shall be in accordance with accepted standard [C-2(24)].

3.4.18.1 *Single packer method*

This method shall be adopted when the bottom elevation of the test section is the same as the bottom of the drill hole and where it is considered necessary to know the permeability value during drilling itself. This test shall be useful where the full length of the hole cannot stand encased or ungrouted. The packer shall be fixed at the top level of the test section, such that only the test section lies below the packer. Water shall then be pumped through a pipe into the test section under a required pressure and maintaining it till a constant quantity of water intake is observed. The amount of water percolating through the hole shall be recorded at every 5 min intervals. The test shall be repeated by increasing the pressure at regular intervals up to a pressure limit as specified in accordance to accepted standard [C-2(24)]. The details and observations during the test shall be suitably recorded in a proforma recommended in the accepted standard [C-2(24)].

3.4.18.2 *Double packer method*

This method shall be used when the permeability of an isolated section inside a drill hole is to be determined. Packers shall be fixed both at the top and bottom of the test section such that their spacing is exactly equal to the length of the test section.

3.4.19 *Field California Bearing Ratio* (*CBR*) *Test*

This test is carried out to determine the *in-situ* CBR value of the compacted subgrade on which the road pavement will be constructed so as to confirm that the *in-situ* CBR value is equal to or greater than the design CBR value for the road pavement. The test involves applying static loading to cause penetration of a cylindrical plunger of standard diameter into the compacted subgrade material and recording the applied static load to cause the required increments of penetration till the required maximum penetration of the plunger is achieved. Based on the plot of the recorded applied load and corresponding penetrations of the plunger, the CBR value is determined as the ratio of the applied test load to the predefined standard load for different standard penetrations of the plunger. The equipment and accessories required for carrying out the test, the test procedure, recording of observations and presentation of results shall be in accordance with accepted standard [C-2(25)].

3.4.20 *Optical and Acoustic Tele-Viewer Methods*

The optical and acoustic tele-viewers provide a continuous, 360°view of the borehole wall that allows rock mass discontinuities to be identified and characterized. Both devices can be oriented within the borehole so that the absolute orientation of features like bedding planes can be measured. An optical tele-viewer (OTV) uses a camera to record high-resolution images of the borehole wall and includes lights for illumination. An OTV is best suited for dry boreholes or boreholes filled with clear water.

Any conditions that produce cloudy or murky water or coatings on the borehole wall, limit the usefulness of the OTV. If good images are obtained, it is possible to identify locations and orientations of joints, bedding planes, foliations, faults, shears and other naturally occurring rock mass discontinuities.

The acoustic tele-viewer (ATV) uses ultrasound pulses from a rotating sensor in an open, fluid-filled borehole to record the amplitude and travel time of the signals reflected at the (high-impedance) interface between fluids and the borehole wall. Because an ATV uses ultrasound rather than visible light, the borehole fluid is not required to be clear. Rock mass discontinuities in the wall of the borehole will change the amplitude of the reflected acoustic wave compared to the surrounding material. The method does not work well in soil because of the lack of a high-impedance boundary between the fluid and soil. ATV surveys are used to provide information regarding locations and orientations of joints, bedding planes, faults, shears and other naturally occurring rock mass discontinuities.

3.5 Sampling and Testing

3.5.1 In order to identify the type of soil/rock and to determine the physical, chemical and engineering properties of sub strata, samples of soil, rock and water, as applicable are collected during the investigation. The samples are of the following two types:

a) *Disturbed sample* — The sample in which natural structure of the material is disturbed; and

b) *Undisturbed sample* — The sample in which the natural structure of the material is not disturbed.

3.5.2 The type of sample, quantity of sample and number of samples to be collected depends on the purpose of investigation and the nature of the strata condition. The interval at which the samples are collected depends on the type of strata variation of the profiles within the strata. Generally, undisturbed samples (UDS) are collected at depth interval of 3.0 m or change of strata, whichever is lower. The depth between UDS and SPT are generally staggered at 1.5 m so that at every 1.5 m depth either UDS is collected or SPT is conducted. In case of variations of profiles within a stratum, the samples shall be collected at a frequency of at least every 1.5 m to 2 m depth interval in a borehole. Wherever undisturbed sampling is not possible, such as in cohensionless soil or some utility service is encountered during the investigation, the same may be replaced by standard penetration test. In cohesive soils, when N value is above 32, undisturbed samples may be replaced by standard penetration test.

3.5.3 The following are the methods that are usually employed for sampling:

Nature of stratum	*Type of sample*	*Method of sampling*
Soil	Disturbed	Shovel, pick axe, etc Auger and shell boring Split spoon sampler
	Undisturbed	Block sample Tube sampler Piston sampler Core cutter sampler Continuous soil sampler
Rock	Disturbed	Blasting Chiseling
	Undisturbed	Coring

3.5.4 In cohesive soils, it is possible to collect undisturbed samples for examination and testing. In cohesionless soils below water table, undisturbed sampling is difficult with the samplers other than piston sampler.

3.5.5 Disturbed soil sample and undisturbed soil sample are to be obtained as per **3.5.5.1** and **3.5.5.2**, respectively.

3.5.5.1 *Disturbed soil sample*

Disturbed sample of soil is obtained during the course of excavation of trial pit, boring and after conducting standard penetration test. This sample can be used for testing of physical and chemical properties. The disturbed sample of clay is also useful for determining shear strength of remoulded sample.

3.5.5.2 *Undisturbed soil sample*

Undisturbed sample is obtained from pits and boreholes in such a manner that moisture content and structure do not get altered. This may be attained by careful protection, packing and by the use of a correctly designed sampler. Various methods of undisturbed sampling are as given in good practice [C-2(8)].

3.5.6 *Protection, Handling and Labelling of Samples*

Care should be taken in protecting, handling and subsequent transport of samples and in their full labelling, so that samples can be received in a fit state for examination and testing and can be correctly recognized as coming from a specified trial pit or boring.

3.5.7 *Examination and Testing of Samples*

3.5.7.1 The following tests shall be carried out in accordance with accepted standard [C-2(26)]:

a) *Test on disturbed/undisturbed soil samples*
   1) Visual and engineering classification;
   2) Sieve analysis and hydrometer analysis;

   3) Atterberg limits (liquid limit, plastic limit and shrinkage limit);
   4) Specific gravity;
   5) Free swell index;
   6) Light/Heavy compaction test (standard/modified proctor compaction test);
   7) California bearing ratio;
   8) Relative density (for sand); and
   9) Laboratory permeability test (constant head/falling head).

b) *Test on undisturbed soil samples*
   1) Bulk density and moisture content;
   2) Unconfined compression test (on remoulded or undisturbed sample);
   3) Swelling pressure (on undisturbed and remoulded sample);
   4) Direct shear test (drained/undrained) (on remoulded or undisturbed sample);
   5) Triaxial compression tests (on undisturbed or remoulded sample):
      i) Unconsolidated undrained;
      ii) Consolidated undrained test with/without the measurement of pore water pressure; and
      iii) Consolidated drained;
   6) Consolidation test; and
   7) Vane shear test.

c) *Test on rock samples*
   1) Visual classification;
   2) Water absorption;
   3) Porosity;
   4) Density;
   5) Specific gravity;
   6) Hardness;
   7) Slake durability;
   8) Uniaxial compression test (both saturated and unsaturated);
   9) Point load strength index;
   10) Deformability test (both saturated and unsaturated);
   11) Tensile strength (Brazilian); and
   12) Triaxial compression test.

d) *Chemical analysis on subsoil and ground water* — Tests are conducted to determine the concentration of following chemicals:
   1) *p*H value;
   2) Sulphates (SO_3 and/or SO_4);
   3) Chlorides;
   4) Organic matter; and
   5) Any other chemicals harmful to the foundation material.

In case of ground water, colour, odour, turbidity and specific conductivity should also be determined.

3.6 Soil Investigation Report

3.6.1 *General*

On completion of the *in-situ* and laboratory tests, subsurface investigation report shall be prepared which should include, geological information, procedure adopted for investigation, field observations, laboratory test data, analysis, interpretation, recommendation, etc.

3.6.2 *Information to be Provided*

3.6.2.1 The report shall include but not be limited to the following:

a) Plan showing location and depth of *in-situ* tests;

b) Geological information of the area;

c) General topography of the site;

d) Past usage and historical data of the site, if available;

e) Borelog/trial pit log (*see* good practice [C-2(8)] for format of borelog);

f) *In-situ* test results;

g) Plot of standard penetration test (N values both uncorrected and corrected) with depth for identified areas;

h) Laboratory test results (*see* good practice [C-2(8)] for format for laboratory test results);

j) Summary of strata profile; and

k) In case of pressuremeter tests, the following should be furnished:

    1) Calibration record including, description of membrane and sheath on probes, dimension of thick walled cylinder, length of flexible tubing, calibration curves/chart, temperature, etc;

    2) Drilling record including, borehole number, method of making borehole, log of soil type and condition, depth of water in borehole, weather and temperature; and

    3) *Test record* — Type of test, date and time, depth of centre point of probe, volume readings at 30 s and 60 s elapsed time and corresponding pressure readings, notes on any deviation from standard test procedure.

3.6.2.2 Reporting of *in-situ* and laboratory test results should be in accordance with relevant Indian Standards.

3.6.3 *Analysis and Interpretation of Results*

The following shall be included in the report:

a) Analysis of test results;

b) Discussion and interpretation of results analyzed including basis of adopting design parameters for the substrata;

c) For shallow foundations:

    1) Net allowable bearing pressure considering shear as well as settlement criteria for isolated footing, continuous strip footing and raft foundation; and

    2) Modulus of subgrade reaction and modulus of elasticity of substrata.

d) For pile foundations: Safe load carrying capacity;

e) Dynamic soil properties such as shear wave velocity, dynamic shear modulus, Poisson's ratio, damping ratio, as applicable;

f) Suitability of the soil for backfilling around foundations;

g) Susceptibility of sub-soil strata to liquefaction, if any, in the event of dynamic loading; and

h) Remedial measures against the presence of harmful chemicals in the sub-soil/ground water.

4 CLASSIFICATION AND IDENTIFICATION OF SOILS

The classification and identification of soils for engineering purposes shall be in accordance with accepted standard [C-2(27)].

5 MATERIALS

5.1 Cement, coarse aggregate, fine aggregate, lime, *Surkhi*, steel, timber and other materials go into the construction of foundations shall conform to the requirements of Part B 'Building Materials' of this NBCS.

5.2 Protection Against Deterioration of Materials

Where a foundation is to be in contact with soil, water or air, that is, in a condition conducive to the deterioration of the materials of the foundation, protective measures shall be taken to minimize the deterioration of the materials.

5.2.1 *Concrete*

The concrete used for construction shall be in accordance with Part C 'Structural Design/ Section 5 Structural Concrete' of this NBCS.

5.2.2 *Timber*

Where timber is exposed to soil, it shall be treated in accordance with good practice [C-2(28)].

6 GENERAL REQUIREMENTS FOR FOUNDATIONS/SUB-STRUCTURES FOR BUILDINGS

6.1 Types of Foundations

Types of foundations for buildings covered in this Section are:

a) *Shallow foundations* (*see* **7**)
    1) Pad or spread and strip foundations (*see* **7.3**);
    2) Raft foundations (*see* **7.4**);
    3) Ring foundations (*see* **7.5**); and
    4) Shell foundations (*see* **7.6**).

b) *Deep foundations*
    1) Pile Foundations
        i) Driven cast *in-situ* concrete piles (*see* **8.2**);
        ii) Bored cast *in-situ* concrete piles (*see* **8.2**);
        iii) Driven precast concrete piles (*see* **8.3**);
        iv) Precast concrete piles in prebored holes (*see* **8.4**);
        v) Under-reamed concrete piles (*see* **8.5**);
        vi) Timber piles (*see* **8.6**); and
        vii) Spun piles.

        NOTE — Spun piles are used in deep marshy soils as conventional pile installation beyond 50 m in such soils is very difficult.

c) *Other foundations/Sub-structures/Foundations for special structure*
    1) Pier foundations (*see* **10.1**);
    2) Combined piled-raft foundation (*see* **9**);
    3) Diaphragm walls (*see* **10.2**); and
    4) Machine foundations (*see* **10.2**).

6.2 Depth of Foundations

6.2.1 The depth to which foundations should be carried depends upon the following principal factors:

a) Getting adequate allowable bearing capacity;

b) In the case of clayey soils, penetration below the zone where shrinkage and swelling due to seasonal weather changes and due to trees and shrubs are likely to cause appreciable movements;

c) In fine sands and silts, penetration below the depth of frost penetration;

d) Maximum depth of scour, wherever relevant, should also be considered and the foundation should be located sufficiently below this depth; and

e) Other factors such as ground movements and heat transmitted from the building to the supporting ground may be important.

6.2.2 All foundations shall extend to a depth of at least 500 mm below natural ground level. On rock or such other weather resisting natural ground, removal of the top soil may be all that is required. In such cases, the surface shall be cleaned and, if necessary, stepped or otherwise prepared so as to provide a suitable bearing and thus prevent slipping or other unwanted movements.

6.2.3 Where there is excavation, ditch, pond, water course, filled-up ground or similar condition of the subsoil on which the structure is to be erected, the foundation of such structure shall either be carried down to a depth beyond the detrimental influence of such conditions, or retaining walls shall be provided for the purpose of shielding from the effects of such conditions.

6.2.4 A foundation in any type of soil shall be below the zone significantly weakened by root holes or cavities produced by burrowing animals or works. The depth shall also be enough to prevent the rainwater scouring below the footings.

6.2.5 Clayey soils, like black cotton soils, are seasonally affected by drying, shrinkage and cracking in dry and hot weather and by swelling in the following wet weather to a depth which will vary according to the nature of the clay and the climatic condition of the region. It is necessary in these soils, either to place the foundation bearing at such a depth where the effects of seasonal changes are not important or to make the foundation capable of eliminating the undesirable effects due to relative movement by providing flexible type of construction or rigid foundations. Adequate load counteracting against swelling pressures also provide satisfactory foundations.

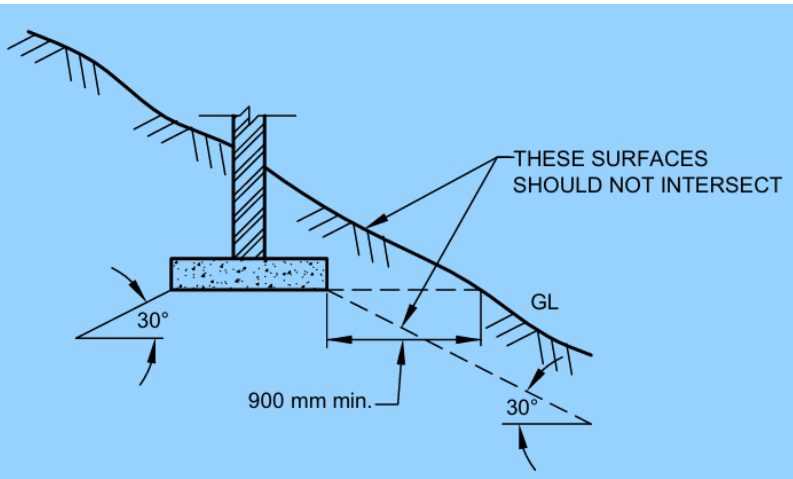
6.3 Foundation at Different Levels

6.3.1 Where footings are adjacent to sloping ground or where the bottoms of the footings of a structure are at different levels or at levels different from those of the footings of adjoining structures, the depth of the footings shall be such that the difference in footing elevations shall be subject to the following limitations:

a) When the ground surface slopes downward adjacent to a footing, the sloping surface shall not intersect a frustum of bearing material under the footing having sides which make an angle of 30° with the horizontal for soil and horizontal distance from the lower edge of the footing to the sloping surface shall be at least 600 mm for rock and 900 mm for soil (*see* Fig. 4);

b) In the case of footings in granular soil, a line drawn between the lower adjacent edges of adjacent footings shall not have a steeper slope than one vertical to two horizontal (*see* Fig. 5); and

c) In case of footing in clayey soils a line drawn between the lower adjacent edge of the upper footing and the upper adjacent edge of lower footing shall not have a steeper slope than one vertical to two horizontal (*see* Fig. 6).



THESE SURFACES SHOULD NOT INTERSECT

FIG.6 FOOTING IN CLAYEY SOIL

6.3.2 The requirement given in 6.3.1 shall not apply in the condition where adequate provision is made for the lateral support (such as with retaining walls) of the material supporting the higher footing.

6.4 Effect of Seasonal Weather Changes

During periods of hot, dry weather a deficiency of water develops near the ground surface and in clay soils, that is associated with a decrease of volume or ground shrinkage and the development of cracks. The shrinkage of clay will be increased by drying effect produced by fast growing and water seeking trees. The range of influence depends on size and number of trees and it increase during dry periods. In general, it is desirable that there shall be a distance of at least 6 m between such trees. Boiler installations, furnaces, kilns, underground cables and refrigeration installations and other artificial sources of heat may also cause increased volume changes of clay by drying out the ground beneath them, the drying out can be to a substantial depth. Special precautions either in the form of insulation or otherwise should be taken. In periods of wet weather, clay soils swell and the cracks lend to close, the water deficiency developed in the previous dry periods may be partially replenished and a subsurface zone or zones deficient in water may persist for many years. Leakage from water mains and underground sewers may also result in large volume changes. Therefore, special care shall be taken to prevent such leakages.

6.5 Effect of Mass Movements of Ground in Unstable Areas

In certain areas mass movements of the ground are liable to occur from causes independent of the loads applied by the foundations of structures. These include mining subsidence, landslides on unstable slopes and creep on clay slopes.

6.5.1 *Mining Subsidence*

In mining areas, subsidence of the ground beneath a building or any other structure is liable to occur. The magnitude of the movement and its distribution over the area are likely to be uncertain and attention shall, therefore, be directed to make the foundations and structures sufficiently rigid and strong to withstand the probable worst loading condition and probable ground movements. Where future subsidence is likely, care should be taken to design the superstructure and foundation sufficiently strong to cater for probable ground movements. Long continuous buildings should be avoided in such areas and large building in such area should be divided into independent sections of suitable size, each with its own foundations. Expert advice from appropriate mining authority should be sought.

NOTE — For prediction of subsidence in coal mines, guidelines as given in the accepted standard [C-2(29)] may be referred.

6.5.2 *Landslide Prone Areas*

The construction of structures on slopes which are suspected of being unstable and are subject to landslip shall be avoided.

On sloping ground on clay soils, there is always a tendency for the upper layers of soil to move downhill, depending on type of soil, the angle of slope, climatic conditions, etc. In some cases, the uneven surface of the slope on a virgin ground will indicate that the area is subject to small land slips and, therefore, if used for foundation, will obviously necessitate special design consideration as specified in accepted standard [C-2(30)].

Where there may be creep of the surface layer of the soil, protection against creep may be obtained by following special design considerations.

On sloping sites, spread foundations shall be on a horizontal bearing and stepped. At all changes of levels, they shall be lapped at the steps for a distance at least equal to the thickness of the foundation or twice the height of the step, whichever is greater. The steps shall not be of greater height than the thickness of the foundation, unless special precautions are taken.

Cuttings, excavations or sloping ground near and below foundation level may increase the possibility of shear failure of the soil. The foundation shall be well beyond the zone of such shear failure.

If the probable failure surface intersects a retaining wall or other revetment, the latter shall be made strong enough to resist any unbalanced thrust. In case of doubt as to the suitability of the natural slopes or cuttings, the structure shall be kept well away from the top of the slopes, or the slopes shall be stabilized.

Cuttings and excavations adjoining foundations reduce stability and increase the likelihood of differential settlement. Their effect should be investigated not only when they exist but also when there is possibility that they are made subsequently.

Where a structure is to be placed on sloping ground, additional complications are introduced. The ground itself, particularly if of clay, may be subject to creep or other forms of instability, which may be enhanced if the strata dip in the same direction as the ground surface. If the slope of the ground is large, the overall stability of the slope and substructure may be affected. These aspects should be carefully investigated.

6.6 Precautions for Foundations on Inclined Strata

In the case of inclined strata, if they dip towards a cutting of basement, it may be necessary to carry foundation below the possible slip planes, land drainage also requires special consideration, particularly on the uphill side of a structure to divert the natural flow of water away from the foundations.

6.7 Strata of Varying Thickness

Strata of varying thickness, even at appreciable depth, may increase differential settlement. Where necessary, calculations should be made of the estimated settlement from different thickness of strata and the structure should be designed accordingly. When there is large change of thickness of soft strata, the stability of foundation may be affected. Site investigations should, therefore, ensure detection of significant variations in strata thickness.

6.8 Layers of Softer Material

Some soils and rocks have thin layers of softer material between layers of harder material, which may not be detected unless thorough investigation is carried out. The softer layers may undergo marked changes in properties if the loading on them is increased or decreased by the proposed construction or affected by related changes in ground water conditions. These should be taken into account.

6.9 Spacing Between Existing and New Foundation

The deeper the new foundation and the nearer to the existing it is located, the greater the damage is likely to be. Preferably, the minimum horizontal spacing between existing and new footings shall be equal to the width of the wider clear footing. While the adoption of such provision shall help minimizing damage to adjacent foundation, an analysis of bearing capacity and settlement shall be carried out to have an appreciation of the effect on the adjacent existing foundation. Suitable site-specific protection measures shall be adopted for the existing foundation, as required.

6.10 Preliminary Work for Construction

6.10.1 The construction of access roads, main sewers and drains should preferably be completed before commencing the work of foundations; alternatively, sufficient precautions shall be taken to protect the already constructed foundations during subsequent work.

6.10.2 *Clearance of Site*

Any obstacles, including the stump of trees, likely to interfere with the work shall be removed. Holes left by digging, such as those due to removal of old foundation, uprooted trees, burrowing by animals, etc, shall be back-filled with soil and well compacted.

6.10.3 *Drainage*

If the site of a structure is such that surface water drain towards it, land may be dressed or drains laid to divert the water away from the site.

6.10.4 *Setting Out*

Generally, the site shall be levelled before the layout of foundations are set out. In case of sloping terrain, care shall be taken to ensure that the dimensions on plans are set out correctly in one or more horizontal planes.

6.10.5 The layout of foundations shall be set out in accordance of good practice [C-2(31)]. The setting out of walls shall be facilitated by permanent row of pillars, parallel to and at a suitable distance beyond the periphery of the building. The pillars shall be located at junctions of cross walls with the peripheral line of pillars. The centre lines of the cross walls shall be extended to and permanently erected on the plastered tops of the corresponding sets of pillars. The datum lines parallel to and at the known fixed distance from the centre lines of the external walls also be permanently worked on the corresponding rows of pillars to pillars to serve as checks on the accuracy of the work as it proceeds. The tops of these pillars shall be at the same level and preferably at the plinth or floor level. The pillars shall be of sizes not less than 250 mm wide and shall be bedded sufficiently deep into ground, so that they are not disturbed.

6.11 Protection of Excavation

6.11.1 The protection of excavation during construction shall be done in accordance with good practice [C-2(32)].

6.11.2 After excavation, the bottom of the excavation shall be cleared of all loose soil and rubbish and shall be levelled, where necessary. The bed shall be wetted and compacted by heavy rammers to an even surface.

6.11.3 Excavation in clay or other soils that are liable to be effected by exposure to atmosphere shall, wherever possible, be concreted as soon as they are dug. Alternatively, the bottom of the excavation shall be protected immediately by 80 mm thick layer of cement concrete not leaner than mix 1 : 5 : 10 over which shall come the foundation concrete; or in order to obtain a dry hard bottom, the last excavation of about 100 mm shall be removed only before concreting.

6.11.4 The backfilling of the excavation shall be done with care so as not to disturb the constructed foundation and shall be compacted in layers not exceeding 150 mm thick with sprinkling of minimum quantity of water necessary for proper compaction.

6.11.5 To support excavation sides where open excavation is required beyond a certain depth and safe slopes are not feasible, shoring shall be provided. This ensures stability, allows near-vertical soil cutting and prevents soil collapse. Shoring systems can include concrete shoring pile walls (secant or tangent wall systems), soldier pile walls, diaphragm walls, or other suitable methods, depending on soil conditions, excavation depth and selected construction technology.

Temporary shoring is generally defined as a system intended for service for a limited period. If earth retention structures are required for an extended duration, they should be designed as permanent structures.
For temporary shoring, the design should consider soil pressure and ensure that the selected system, including piles and anchors (if provided), can safely support the applied loads under service conditions.

The type of earth pressure to be considered depends on the flexibility and support conditions of the shoring system. Cantilevered or flexible walls with limited support require a specific earth pressure approach, whereas more rigid walls that exhibit minimal deflection require a different consideration.

For permanent conditions, all final loads, including surcharge effects, must be resisted by the structural walls, designed with appropriate safety considerations. The structural design should ensure:

a) deflections remain within allowable limits; and

b) structural elements maintain adequate strength and stability.

6.12 Alterations During Construction

a) Where during construction the soil or rock to which foundation is to transfer loads is found not to be the type or in the condition assumed, the foundation shall be redesigned and constructed for the existing type or conditions and the Authority notified;

b) Where a foundation bears on gravel, sand or silt and where the highest level of the ground water is or likely to be higher than an elevation defined by bearing surface minus the width of the footing, the bearing pressure shall be suitably altered;

c) Where the foundation has not been placed or located as indicated earlier or is damaged or bears on a soil whose properties may be adversely changed by climatic and construction conditions, the error shall be corrected, the damaged portion repaired or the design capacity of the affected foundation recalculated to the satisfaction of the Authority; and

d) Where a foundation is placed and if the results of a load test so indicate, the design of the foundation shall be modified to ensure structural stability of the same.

7 SHALLOW FOUNDATIONS

7.1 Design Information

For the satisfactory design of foundations, the following information is necessary:

a) Type and condition of the soil or rock to which the foundation transfers the loads;

b) General layout of the columns and load-bearing walls showing the estimated loads, including moments and torques due to various loads (dead load, imposed load, wind load, seismic load) coming on the foundation units;

c) Allowable bearing pressure of the soils;

d) Changes in ground water level, drainage and flooding conditions and also the chemical conditions of the subsoil water;

e) Behaviour of the buildings, topography and environment/surroundings adjacent to the site, the type and depths of foundations and the bearing pressure; and

f) Seismic zone of the region.

7.2 Design Considerations

7.2.1 *Design Loads*

The foundation shall be proportioned for the following combination of loads:

a) Dead load + Imposed load; and

b) Dead load + Imposed load + Wind load or seismic loads, whichever is critical.

For details, reference shall be made to Part C 'Structural Design/ Section 1 Loads and Load Effects' of this NBCS.

NOTE — For shallow foundations on coarse grained soils, settlements shall be estimated corresponding to **7.2.1**(b) and for foundations on fine grained soils, the settlement shall be estimated corresponding to permanent loads only. Permanent loads shall be in accordance with good practice [C-2(33)].

7.2.2 *Allowable Bearing Pressure*

The allowable bearing pressure shall be taken as either of the following, whichever is less:

a) the safe bearing capacity on the basis of shear strength characteristics of soil; and

b) the bearing pressure that the soil can take without exceeding the permissible settlement (*see* **7.2.3**).

7.2.2.1 *Bearing capacity by calculation*

Where the engineering properties of the soil are available, that is, cohesion, angle of internal friction, density, etc, the bearing capacity shall be calculated from stability considerations of shear; factor of safety of 2.5 shall be adopted for safe bearing capacity. The effect of interference of different foundations should be taken into account. The procedure for determining the ultimate bearing capacity and bearing pressure of shallow foundations based on shear and allowable settlement criteria shall be in accordance with good practice [C-2(34)]. Depth factor correction is to be applied only when backfilling is done with proper compaction.

7.2.2.2 *Field method for determining allowable bearing pressure*

Where appropriate, plate load tests can be performed and allowable pressure determined as per accepted standard [C-2(9)]. The allowable bearing pressure for sandy soils may also be obtained by loading tests. When such tests cannot be done, the allowable bearing pressure for sands may be determined using penetration test.

7.2.2.3 Where the bearing materials directly under a foundation over-lie a stratum having smaller safe bearing capacity, these smaller values shall not be exceeded at the level of such stratum.

7.2.2.4 *Effect of wind and seismic force*

7.2.2.4.1 Where the bearing pressure due to wind is less than 25 percent of that due to dead and imposed loads, it may be neglected in design. Where this exceeds 25 percent, foundations may be so proportioned that the pressure due to combined dead, imposed and wind loads does not exceed the allowable bearing pressure by more than 25 percent.

7.2.2.4.2 When earthquake forces are considered for the computation of design loads, the permissible increase in bearing pressure of pertaining soil shall be as given in Part C 'Structural Design/Section 1 Loads and Load Effects'of this NBCS, depending upon the type of foundation of the structure and the type of soil.

7.2.2.5 *Bearing capacity of buried strata*

If the base of a foundation is close enough to a strata of lower bearing capacity, the latter may fail due to excess pressure transmitted to it from above. Care should be taken to see that the pressure transmitted to the lower strata is within the prescribed safe limits. When the footings are closely spaced, the pressure transmitted to the underlying soil will overlap. In such cases, the pressure in the overlapped zones will have to be considered. With normal foundations, it is sufficiently accurate to estimate the bearing pressure on the underlying layers by assuming the load to be spread at a slope of 2 (vertical) to 1 (horizontal).

7.2.3 *Settlement*

The permissible values of total and differential settlement for a given type of structure may be taken as given in Table 3. Total settlements of foundation due to net imposed loads shall be estimated in accordance with accepted standard [C-2(6)]. The following causes responsible for producing the settlement shall be investigated and taken into account.

a) *Causes of Settlement*:

   1) Elastic compression of the foundation and the underlying soil;
   2) Consolidation including secondary compression;
   3) *Ground water lowering* — Specially repeated lowering and raising of water level in loose granular soils tend to compact the soil and cause settlement of the footings. Prolonged lowering of the water table in fine grained soils may introduce settlement because of the extrusion of water from the voids. Pumping water or draining water by tiles or pipes from granular soils without an adequate mat of filter material as protection may, in a period of time, carry a sufficient amount of fine particles away from the soil and cause settlement;
   4) Seasonal swelling and shrinkage of expansive clays;
   5) Ground movement on earth slope, for example, surface erosion, slow creep or landslides; and
   6) Other causes, such as adjacent excavation, mining, subsidence and underground erosion.

b) *Causes of Differential Settlements*:

   1) Geological and physical non-uniformity or anomalies in type, structure, thickness and density of the soil medium (pockets of sand in clay, clay lenses in sand, wedge like soil strata, that is, lenses in soil), an admixture of organic matter, peat, mud;
   2) Non-uniform pressure distribution from foundation to the soil due to non-uniform loading and incomplete loading of the foundations;
   3) Water regime at the construction site,
   4) Overstressing of soil at adjacent site by heavy structures built next to light ones;
   5) Overlap of stress distribution in soil from adjoining structures;
   6) Unequal expansion of the soil due to excavation for footing;

7) Non-uniform development of extrusion settlements; and

8) Non-uniform structural disruptions or disturbance of soil due to freezing and thawing, swelling and softening and drying of soils.

7.2.4 *Shallow Foundations on Rocks*

Estimation of the safe bearing pressures of rocks for shallow foundations based on strength, allowable settlement and classification criteria; and also design and construction of shallow foundations on rocks shall be carried out in accordance with the good practice [C-2(35)].

7.3 Pad or Spread and Strip Foundations

7.3.1 In such type of foundations, wherever the resultant of the load deviates from the centre line by more than 1/6 of its least dimension at the base of footing, it should be suitably reinforced.

7.3.2 For continuous wall foundations (plain or reinforced) adequate reinforcement should be provided particularly at places where there is abrupt change in magnitude of load or variation in ground support.

7.3.3 On sloping sites the foundation should have a horizontal bearing and stepped and lapped at changes of levels for a distance at least equal to the thickness of foundation or twice the height of step, whichever is greater. The steps should not be of greater height than thickness of the foundations.

7.3.4 *Ground Beams*

The foundation can also have the ground beam for transmitting the load. The ground beam carrying a load bearing wall should be designed to act with the wall forming a composite beam, when both are of reinforced concrete and structurally connected by reinforcement. The ground beam of reinforced concrete structurally connected to reinforced brick work can also be used.

7.3.5 *Dimensions of Foundation*

The dimensions of the foundation in plan should be such as to support loads as given in good practice [C-2(33)]. The width of the footings shall be such that maximum stress in the concrete or masonry is within the permissible limits. The width of wall foundation (in mm) shall not be less than that given by:

$$B = W + 300$$

where

B = width at base, in mm; and

W = width of supported wall, in mm.

7.3.6 In the base of foundations for masonry foundation it is preferable to have the steps in multiples of thickness of masonry unit.

7.3.7 The plan dimensions of excavation for foundations should be wide enough to ensure safe and efficient working in accordance with good practice [C-2(32)].

7.3.8 Unreinforced foundation may be of concrete or masonry (stone or brick) provided that angular spread of load from the base of column/wall or bed plate to the outer edge of the ground bearing is not more than 1 vertical to 1/2 horizontal for masonry or 1 vertical to 1 horizontal for cement concrete and 1 vertical to 2/3 horizontal for lime concrete. The minimum thickness of the foundation of the edge should not be less than 150 mm. In case the depth to transfer the load to the ground bearing is less than the permissible angle of spread, the foundations should be reinforced.

7.3.9 If the bottom of a pier is to be belled so as to increase its load carrying capacity such bell should be at least 300 mm thick at its edge. The sides should be sloped at an angle of not less than 45° with the horizontal. The least dimension should be 600 mm (circular, square or rectangular). The design should allow for the vertical tilt of the pier by 1 percent of its height.

7.3.10 If the allowable bearing capacity is available only at a greater depth, the foundation can be rested at a higher level for economic considerations and the difference in level between the base of foundation and the depth at which the allowable bearing capacity occurs can be filled up with either: (a) concrete of allowable compressive strength not less than the allowable bearing pressure, (b) incompressible fill material, for example, sand, gravel, etc, in which case the width of the fill should be more than the width of the foundation by an extent of dispersion of load from the base of the foundation on either side at the rate of 2 vertical to 1 horizontal.

7.3.11 The cement concrete foundation (plain or reinforced) should be designed in accordance with Part C 'Structural Design/ Section 5 Structural Concrete' of this NBCS and masonry foundation in accordance with Part C 'Structural Design/ Section 4 Masonry' of this NBCS.

7.3.12 *Thickness of Footing*

The thickness of different types of footings, if not designed according to **7.2**, should be as given in Table 4.

Table 3 Permissible Differential Settlements and Tilt (Angular Distortion) for Shallow Foundations in Soils

(*Clause* 7.2.3)

Sl No.	**Type of Structure**	**Isolated Foundations**						**Raft Foundations**

	a) For normal structures	a) 200 mm;	—
		b) Twice the maximum offset in a stepped footing; and	For footings resting on soil
		c) 300 mm.	For footings resting on top of the pile
	b) For lightly loaded structures	a) 150 mm; and	Resting on soil
		b) 200 mm.	Resting on pile
iii)	Reinforced concrete	a) 150 mm; and	Resting on soil
		b) 300 mm.	Resting on pile

7.3.13 *Land Slip Area*

On a sloping site, spread foundation shall be on a horizontal bearing and stepped. At all changes of levels, they shall be lapped at the steps for a distance at least equal to the thickness of the foundation or twice the height of the step, whichever is greater. The steps shall not be of greater height than the thickness of the foundation unless special precautions are taken. On sloping ground on clay soils, there is always a tendency for the upper layers of soil to move downhill, depending on type of soil, the angle of slope, climatic conditions, etc. Special precautions are necessary to avoid such a failure.

7.3.14 In the foundations, the cover to the reinforcement shall be as prescribed in Part C 'Structural Design/ Section 5 Structural Concrete' of this NBCS for the applicable environment exposure condition.

7.3.15 For detailed information regarding preparation of ground work, reference shall be made to good practice [C-2(36)].

7.4 Raft Foundations

7.4.1 *Design Considerations*

Design provisions given in 7.2 shall generally apply.

7.4.1.1 The structural design of reinforced concrete rafts shall conform to Part C 'Structural Design/Section 5 Structural Concrete' of this NBCS.

7.4.1.2 In the case of raft, whether resting on soil directly or on lean concrete, the cover to the reinforcement shall be as prescribed in Part C 'Structural Design/ Section 5 Structural Concrete' of this NBCS for the applicable environment exposure condition.

7.4.1.3 In case the structure supported by the raft consists of several parts with varying loads and heights, it is advisable to provide separation joints between these parts. Joints shall also be provided, wherever there is a change in the direction of the raft.

7.4.1.4 Foundations subject to heavy vibratory loads should preferably be isolated.

7.4.1.5 The minimum depth of foundation shall generally be not less than 1 m.

7.4.1.6 *Dimensional parameters*

The size and shape of the foundation adopted affect the magnitude of subgrade modulus and long term deformation of the supporting soil and this, in turn, influences the distribution of contact pressure. This aspect needs to be taken into consideration in the analysis.

7.4.1.7 *Eccentricity of loading*

A raft generally occupies the entire area of the building and often it is not feasible and rather uneconomical to proportion it coinciding the centroid of the raft with the line of action of the resultant force. In such cases, the effect of the eccentricity on contact pressure distribution shall be taken into consideration.

7.4.1.8 *Properties of supporting soil*

Distribution of contact pressure underneath a raft is affected by the physical characteristics of the soil supporting it. Consideration shall be given to the increased contact pressure developed along the edges of foundation on cohesive soils and the opposite effect on granular soils. Long term consolidation of deep soil layers shall be taken into account in the analysis. This may necessitate evaluation of contact pressure distribution both immediately after construction and after completion of the consolidation process. The design shall be based on the worst conditions.

7.4.1.9 *Rigidity of foundations*

Rigidity of the foundation tends to iron out uneven deformation and thereby modifies the contact pressure distribution. High order of rigidity is characterized by long moments and relatively small, uniform settlements. A rigid foundation may also generate high secondary stresses in structural members. The effect of rigidity shall be taken into account in analysis.

7.4.1.10 *Rigidity of the super structure*

Free response of the foundations to soil deformation is restricted by the rigidity of the superstructure. In the extreme case, a stiff structure may force a flexible foundation to behave as rigid. This aspect shall be considered to evaluate the validity of the contact pressure distribution.

7.4.1.11 *Modulus of elasticity and modulus of subgrade reaction*

Annex A enumerates the methods of determination of modulus of elasticity (E_s). The modulus of subgrade reaction (k) may be determined in accordance with Annex B.

7.4.2 *Necessary Information*

The following information is necessary for a satisfactory design and construction of a raft foundation:

a) Site plan showing the location of the proposed as well as the neighbouring structures;

b) Plan and cross-sections of building showing different floor levels, shafts and openings, etc, layout of load bearing walls, columns, shear walls, etc;

c) Loading conditions, preferably shown on a schematic plan indicating combination of design loads transmitted to the foundation;

d) Information relating to geological history of the area, seismicity of the area, hydrological information indicating ground water conditions and its seasonal variations, etc;

e) Geotechnical information giving subsurface profile with stratification details, engineering properties of the founding strata (namely, index properties, effective shear parameters determined under appropriate drainage conditions, compressibility characteristics, swelling properties, results of field tests like static and dynamic penetration tests, pressure meter tests, etc); and

f) A review of the performance of similar structure, if any, in the locality.

7.4.3 *Choice of Raft Type*

7.4.3.1 For fairly small and uniform column spacing and when the supporting soil is not too compressible a flat concrete slab having uniform thickness throughout (a true mat) is most suitable [*see* Fig. 7(A)].

7.4.3.2 A slab may be thickened under heavy loaded columns to provide adequate strength for shear and negative moment. Pedestals may also be provided in such cases [*see* Fig. 7(B)].

7.4.3.3 A slab and beam type of raft is likely to be more economical for large column spacing and unequal column loads particularly when the supporting soil is very compressive [*see* Fig. 7(C) and Fig. 7(D)].

7.4.3.4 For very heavy structures, provision of cellular raft or rigid frames consisting of slabs and basement walls may be considered.

7.4.4 *Methods of Analysis*

The essential task in the analysis of a raft foundation is the determination of the distribution of contact pressure underneath the raft which is a complex function of the rigidity of the superstructure, the supporting soil and the raft itself and cannot be determined with exactitude, except in very simple cases. This necessitates a number of simplifying assumptions to make the problem amenable to analysis. Once the distribution of contact pressure is determined, design bending moments and shears can be computed based on statics. The methods of analysis suggested are distinguished by the assumptions involved. Choice of a particular method should be governed by the validity of the assumptions in the particular case.

7.4.4.1 *Rigid foundation* (*conventional method*)

7.4.4.1.1 This method is based on the assumption of linear distribution of contact pressure. The basic assumptions of this method are:

a) the foundations rigid relative to the supporting soil and the compressible soil layer is relatively shallow; and

b) the contact pressure variation is assumed as planar, such that the centroid of the contact pressure coincides with the line of action of the resultant force of all loads acting on the foundation.

7.4.4.1.2 This method may be used when either of the following conditions is satisfied:

a) the structure behaves as rigid (due to the combined action of the superstructure and the foundation) with relative stiffness factor $K > 0.5$ (for evaluation of K, *see* Annex C); and

b) the column spacing is less than $1.75/\lambda$ (*see* Annex C).

7.4.4.1.3 The raft is analyzed as a whole in each of the two perpendicular directions. The contact pressure distribution is determined by the procedure outlined in Annex D. Further analysis is also based on statics.

7.4.4.1.4 In the case of uniform conditions when the variations in adjacent column loads and column spacings do not exceed 20 percent of the higher value, the raft may be divided into perpendicular strips of widths equal to the distance between mid-spans and each strip may be analyzed as an independent beam with known column loads and known contact pressures. Such beams will not normally satisfy statics due to shear transfer between adjacent strips and design may be based on suitable moment coefficients, or by moment distribution.

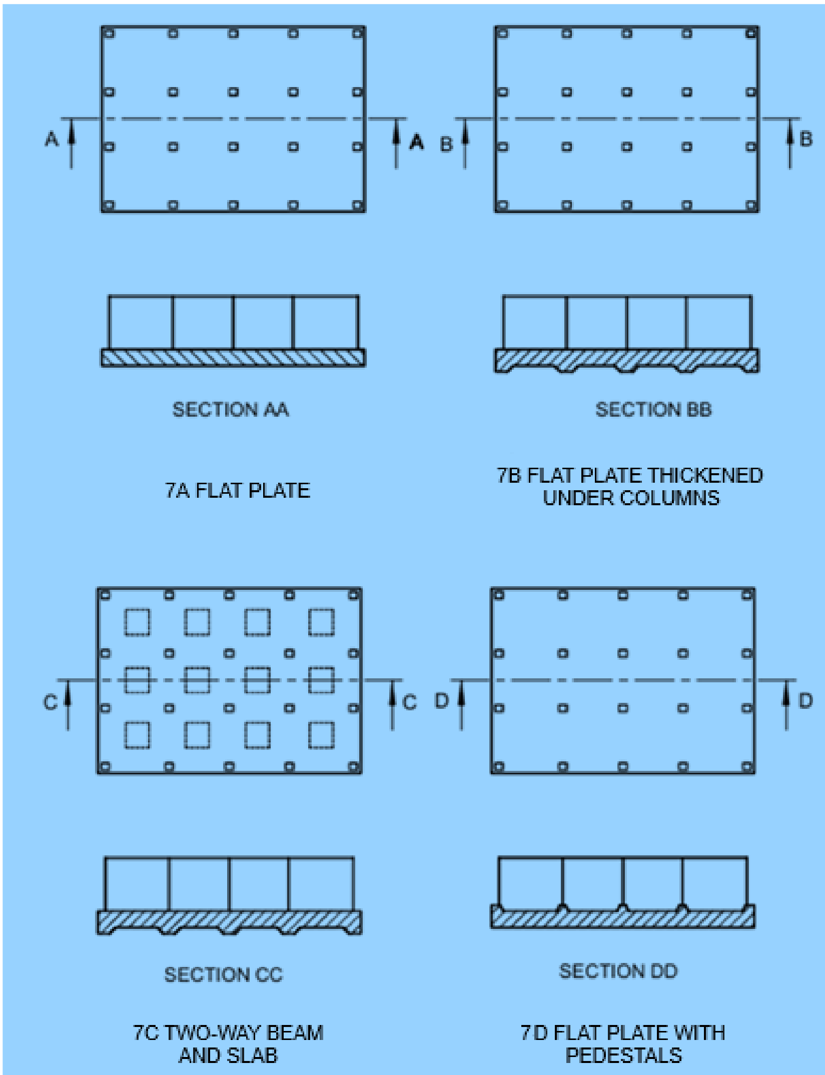
NOTE — On soft soils, for example, normally consolidated clays, peat, muck, organic silts, etc, the assumptions involved in the conventional method are commonly justified.

7.4.4.2 *Flexible foundations*

a) *Simplified method* — In this method, it is assumed that the subgrade consists of an infinite array of individual elastic springs each of which is not affected by others. The spring constant is equal to the modulus of subgrade reaction (*k*). The contact pressure at any point under the raft is, therefore, linearly proportional to the settlement at the point. Contact pressure may be determined as given in Annex E. This method may be used when all the following conditions are satisfied; and

   1) The structure (combined action of superstructure and raft) may be considered as flexible (relative stiffness factor $K < 0.5$, *see* Annex C); and

   2) Variation in adjacent column load does not exceed 20 percent of the higher value.



7A FLAT PLATE

7B FLAT PLATE THICKENED UNDER COLUMNS

7C TWO-WAY BEAM AND SLAB

7D FLAT PLATE WITH PEDESTALS

FIG.7 COMMON TYPES OF RAFT FOUNDATION

b) *General method* — For the general case of a flexible foundation not satisfying the requirements of (a) the method based on closed form solution of elastic plate theory may be used. This method is based on the theory of plates on winkler foundation which takes into account the restraint on deflection of a point provided by continuity of the foundation in orthogonal foundation. The distribution of deflection and contact pressure on the raft due to a column load is determined by the plate theory. Since the effect of a column load on an elastic foundation is damped out rapidly, it is possible to determine the total effect at a point of all column loads within the zone of influence by the method of superimposition. The computation of effect at any point may be restricted to columns of two adjoining bays in all directions. The procedure is outlined in Annex F.

7.5 Ring Foundations

For provisions regarding ring foundations, good practice [C-2(37)] shall be referred to.

7.6 Shell Foundations

For provisions regarding shell foundations, good practice [C-2(38)] shall be referred to.

8 DEEP FOUNDATIONS

8.1 Deep foundations are structural elements used to transfer loads from a building or structure through weak, compressible soil to stronger, more competent soil or rock at depth. They're essential when shallow foundations, such as footings, are not feasible due to inadequate bearing capacity or excessive settlement.

Some important types of deep foundations which are being used in building and other structures are as follows:

a) Pile foundations; and
    1) driven/bored cast *in-situ* concrete piles;
    2) driven precast concrete piles;
    3) precast concrete piles in prebored holes;
    4) under- reamed piles; and
    5) timber piles.
b) Pier foundation

8.2 Driven/Bored Cast *In-Situ* Concrete Piles

8.2.1 *General*

Piles find application in foundations to transfer loads from a structure to competent subsurface strata having adequate load-bearing capacity. The load transfer mechanism from a pile to the surrounding ground is complicated and is not yet fully understood, although application of pile foundations is in practice over many decades. Broadly, piles transfer axial loads either substantially by friction along its shaft and/or by end bearing. Piles are used where either of the above load transfer mechanism is possible depending upon the subsoil stratification at a particular site. Construction of pile foundations require a careful choice of piling system depending upon the subsoil conditions, the load characteristics of a structure and the limitations of total settlement, differential settlement and any other special requirement of a project.

8.2.2 *Materials and Stresses*

8.2.2.1 *Concrete*

Consistency of concrete to be used shall be consistent with the method of installation of piles. Concrete shall be so designed or chosen as to have a homogeneous mix having a slump/workability consistent with the method of concreting under the given conditions of pile installation.

The slump should be 150 mm to180 mm at the time of pouring.

The minimum grade of concrete to be used for bored piling shall be M 25. For sub-aqueous concrete, the requirements specified in Part C ‘Structural Design/ Section 5 Structural Concrete’ of this NBCS shall be followed. The minimum cement content shall be 400 kg/m^3. However, with proper mix design and use of proper admixture the cement content may be reduced but in no case the cement content shall be less than 350 kg/m^3 [*See also* Table 5 (and Notes thereunder) of Part C ‘Structural Design/ Section 5 Structural Concrete’ of this NBCS].

For the concrete, water and aggregates, specifications laid down in Part C ‘Structural Design/ Section 5 Structural Concrete’ of this NBCS shall be followed in general.

The average compressive stress under working load should not exceed 25 percent of the specified works cube strength at 28 days calculated on the total cross-sectional area of the pile. Where the casing of the pile is permanent, of adequate thickness and of suitable shape, the allowable compressive stress may be increased.

8.2.2.2 *Steel reinforcement*

Steel reinforcement shall conform to any one of the types of steel specified in Part C 'Structural Design/ Section 5 Structural Concrete' of this NBCS.

8.2.3 *Design Considerations*

8.2.3.1 *General*

Pile foundations shall be designed in such a way that the load from the structure can be transmitted to the subsurface with adequate factor of safety against shear failure of subsurface and without causing such settlement (differential or total), which may result in structural damage and/or functional distress under permanent/transient loading. The pile shaft should have adequate structural capacity to withstand all loads (vertical, axial or otherwise) and moments which are to be transmitted to the subsoil and shall be designed according to Part C 'Structural Design/ Section 5 Structural Concrete' of this NBCS.

8.2.3.2 *Adjacent structures*

8.2.3.2.1 When working near existing structures, care shall be taken to avoid damage to such structures. The good practice [C-2(39)] may be used as a guide for studying qualitatively the effect of vibration on persons and structures.

8.2.3.2.2 In case of deep excavations adjacent to piles, proper shoring or other suitable arrangement shall be made to guard against undesired lateral movement of soil.

8.2.3.3 *Pile capacity*

The load carrying capacity of a pile depends on the properties of the soil in which it is embedded. Axial load from a pile is normally transmitted to the soil through skin friction along the shaft and end bearing at its tip. A horizontal load on a vertical pile is transmitted to the subsoil primarily by horizontal subgrade reaction generated in the upper part of the shaft. Lateral load capacity of a single pile depends on the soil reaction developed and the structural capacity of the shaft under bending. It would be essential to investigate the lateral load capacity of the pile using appropriate values of horizontal subgrade modulus of the soil. Alternatively, piles may be installed in rake.

8.2.3.3.1 The ultimate load capacity of a pile may be estimated by means of static formula on the basis of soil test results, or by using a dynamic pile formula using data obtained during driving the pile. However, dynamic pile driving formula should be generally used as a measure to control the pile driving at site. Pile capacity should preferably be confirmed by initial load tests {*see* good practice [C-2(40)]}. For rock-socketed piles, reference shall also be made to good practice [C-2(41)] for estimating the load capacity of piles.

The settlement of pile obtained at safe load/working load from load-test results on a single pile shall not be directly used for estimating the settlement of a structure. The settlement may be determined on the basis of subsoil data and loading details of the structure as a whole using the principles of soil mechanics.

8.2.3.3.1.1 *Static formula*

The ultimate load capacity of a single pile may be obtained by using static analysis, the accuracy being dependent on the reliability of the soil properties for various strata. When computing capacity by static formula, the shear strength parameters obtained from a limited number of borehole data and laboratory tests should be supplemented, wherever possible by *in-situ* shear strength obtained from field tests. The two separate static formulae, commonly applicable for cohesive and non-cohesive soil respectively, are indicated in Annex G. Other formula based on static cone penetration test {*see* the accepted standards [C-2(42)]} and standard penetration test {*see* the accepted standard [C-2(6)]} are given in **G-3** and **G-4**.

8.2.3.3.1.2 *Dynamic formula*

For driven piles, any established dynamic formula may be used to control the pile driving at site giving due consideration to limitations of various formulae.

Whenever, double acting diesel hammers or hydraulic hammers are used for driving of piles, manufacturer's guidelines about energy and set criteria may be referred to. Dynamic formulae are not directly applicable to cohesive soil deposits such as saturated silts and clays as the resistance to impact of the tip of the casing will be exaggerated by their low permeability while the frictional resistance on the sides is reduced by lubrication.

8.2.3.3.1.3 *Load test results*

The ultimate load capacity of a single pile is determined with reasonable accuracy from test loading as per good practice [C-2(40)]. The load test on a pile shall not be carried out earlier than four weeks from the time of casting the pile.

8.2.3.3.1.4 *Uplift capacity*

The uplift capacity of a pile is given by sum of the frictional resistance and the weight of the pile (buoyant or total as relevant). The recommended factor of safety is 3.0 in the absence of any pullout test results and 2.0 with pullout test results. Uplift capacity can be obtained from static formula (*see* Annex G) by ignoring end bearing but adding weight of the pile (buoyant or total as relevant).

8.2.3.4 *Negative skin friction or dragdown force*

When a soil stratum, through which a pile shaft has penetrated into a underlying hard stratum, compresses as a result of either it being unconsolidated or it being under a newly placed fill or as a result of remoulding during driving of the pile, a dragdown force is generated along the pile shaft up to a point in depth where the surrounding soil does not move downward relative to the pile shaft. Existence of such a phenomenon shall be assessed and suitable correction shall be made to the allowable load where appropriate.

8.2.3.5 *Structural capacity*

The piles shall have necessary structural strength to transmit the loads imposed on it, ultimately to the soil. In case of uplift, the structural capacity of the pile, that is, under tension should also be considered.

8.2.3.5.1 *Axial capacity*

Where a pile is completely embedded in the soil (having an undrained shear strength not less than 0.01 N/mm^2), its axial load carrying capacity is not necessarily limited by its strength as a long column. Where piles are installed through very weak soils (having an undrained shear strength less than 0.01 N/mm^2), special considerations shall be made to determine whether the shaft would behave as a long column or not. If necessary, suitable reductions shall be made for its structural strength following the normal structural principles covering the buckling phenomenon.

When the finished pile projects above ground level and is not secured against buckling by adequate bracing, the effective length will be governed by the fixity imposed on it by the structure it supports and by the nature of the soil into which it is installed. The depth below the ground surface to the lower point of contraflexure varies with the type of the soil. In good soil the lower point of contraflexure may be taken at a depth of 1 m below ground surface subject to a minimum of 3 times the diameter of the shaft. In weak soil (undrained shear strength less than 0.01 N/mm^2) such as soft clay or soft silt, this point may be taken at about half the depth of penetration into such stratum but not more than 3 m or 10 times the diameter of the shaft, whichever is more. The degree of fixity of the position and inclination of the pile top and the restraint provided by any bracing shall be estimated following accepted structural principles.

The permissible stress shall be reduced in accordance with similar provision for reinforced concrete columns as laid down in Part C 'Structural Design/ Section 5 Structural Concrete' of this NBCS.

8.2.3.5.2 *Lateral load capacity*

A pile may be subjected to lateral force for a number of causes, such as wind, earthquake, water current, earth pressure, effect of moving vehicles or ships, plant and equipment, etc. The lateral load capacity of a single pile depends not only on the horizontal subgrade modulus of the surrounding soil but also on the structural strength of the pile shaft against bending, consequent upon application of a lateral load. While considering lateral load on piles, effect of other co-existent loads, including the axial load on the pile, should be taken into consideration for checking the structural capacity of the shaft. A recommended method for the pile analysis under lateral load is given in Annex H.

Because of limited information on horizontal subgrade modulus of soil and pending refinements in the theoretical analysis, it is suggested that the adequacy of a design should be checked by an actual field load test. In the zone of soil susceptible to liquefaction, the lateral resistance of the soil shall not be considered.

8.2.3.5.2.1 *Fixed and free head conditions*

A group of three or more piles connected by a rigid pile cap shall be considered to have fixed head condition. Caps for single piles shall be interconnected by grade beams in two directions and for twin piles by grade beams in a line transverse to the common axis of the pair so that the pile head is fixed. In all other conditions the pile shall be taken as free headed.

8.2.3.5.3 *Raker piles*

Raker piles are normally provided where vertical piles cannot resist the applied horizontal forces. Generally, the rake will be limited to 1 horizontal to 6 vertical. In the preliminary design, the load on a raker pile is generally considered to be axial. The distribution of load between raker and vertical piles in a group may be determined by graphical or analytical methods. Where necessary, due consideration should be made for secondary bending induced as a result of the pile cap movement, particularly when the cap is rigid. Free-standing raker piles are subjected to bending moments due to their own weight or external forces from other causes. Raker piles, embedded in fill or consolidating deposits, may become laterally loaded owing to the settlement of the surrounding soil. In consolidating clay, special precautions, like provision of permanent casing should be taken for raker piles.

8.2.3.6 *Spacing of piles*

The minimum centre to centre spacing of pile is considered from three aspects, namely:

a) Practical aspects of installing the piles;

b) Diameter of the pile; and

c) Nature of the load transfer to the soil and possible reduction in the load capacity of piles group.

NOTE — In the case of piles of non-circular cross-section, diameter of the circumscribing circle shall be adopted.

8.2.3.6.1 In case of piles founded on hard stratum and deriving their capacity mainly from end bearing the minimum spacing shall be 2.5 times the diameter of the circumscribing circle corresponding to the cross-section of the pile shaft. In case of piles resting on rock, the spacing of two times the said diameter may be adopted.

8.2.3.6.2 Piles deriving their load carrying capacity mainly from friction shall be spaced sufficiently apart to ensure that the zones of soils from which the piles derive their support do not overlap to such an extent that their bearing values are reduced. Generally, the spacing in such cases shall not be less than 3 times the diameter of the pile shaft.

8.2.3.7 *Pile groups*

8.2.3.7.1 In order to determine the load carrying capacity of a group of piles a number of efficiency equations are in use. However, it is difficult to establish the accuracy of these efficiency equations as the behaviour of pile group is dependent on many complex factors. It is desirable to consider each case separately on its own merits.

8.2.3.7.2 The load carrying capacity of a pile group may be equal to or less than the load carrying capacity of individual piles multiplied by the number of piles in the group. The former holds true in case of friction piles, driven into progressively stiffer materials or in end-bearing piles. For driven piles in loose sandy soils, the group capacity may even be higher due to the effect of compaction. In such cases a load test may be carried out on a pile in the group after all the piles in the group have been installed.

8.2.3.7.3 In case of piles deriving their support mainly from friction and connected by a rigid pile cap, the group may be visualized as a block with the piles embedded within the soil. The ultimate load capacity of the group may then be obtained by taking into account the frictional capacity along the perimeter of the block and end bearing at the bottom of the block using the accepted principles of soil mechanics.

8.2.3.7.3.1 When the cap of the pile group is cast directly on reasonably firm stratum which supports the piles, it may contribute to the load carrying capacity of the group. This additional capacity along with the individual capacity of the piles multiplied by the number of piles in the group shall not be more than the capacity worked out as per 8.2.3.7.3.

8.2.3.7.4 When a pile group is subjected to moment either from superstructure or as a consequence of inaccuracies of installation, the adequacy of the pile group in resisting the applied moment should be checked. In case of a single pile subjected to moment due to lateral loads or eccentric loading, beams may be provided to restrain the pile cap effectively from lateral or rotational movement.

8.2.3.7.5 In case of a structure supported on single piles/group of piles resulting in large variation in the number of piles from column to column it may result in excessive differential settlement. Such differential settlement should be either catered for in the structural design or it may be suitably reduced by judicious choice of variations in the actual pile loading. For example, a single pile cap may be loaded to a level higher than that of the pile in a group in order to achieve reduced differential settlement between two adjacent pile caps supported on different number of piles.

8.2.3.8 *Factor of safety*

8.2.3.8.1 Factor of safety should be chosen after considering:

a) the reliability of the calculated value of ultimate load capacity of a pile;

b) the types of superstructure and the type of loading; and

c) allowable total/differential settlement of the structure.

8.2.3.8.2 When the ultimate load capacity is determined from either static formula or dynamic formula, the factor of safety would depend on the reliability of the formula and the reliability of the subsoil parameters used in the computation. The minimum factor of safety on static formula shall be 2.5. The final selection of a factor of safety shall take into consideration the load settlement characteristics of the structure as a whole at a given site.

8.2.3.8.3 Higher value of factor of safety for determining the safe load on piles may be adopted, where:

a) settlement is to be limited or unequal settlement avoided;

b) large impact or vibrating loads are expected; and

c) the properties of the soil may deteriorate with time.

8.2.3.9 *Transient loading*

The maximum permissible increase over the safe load of a pile, as arising out of wind loading, is 25 percent. In case of loads and moments arising out of earthquake effects, the increase of safe load on a single pile shall be as given in 7.2.2.4.2. For transient loading arising out of superimposed loads, no increase is allowed.

8.2.3.10 *Overloading*

When a pile in a group, designed for a certain safe load is found, during or after execution, to fall just short of the load required to be carried by it, an overload up to 10 percent of the pile capacity may be allowed on each pile. The total overloading on the group should not, however, be more than 10 percent of the capacity of the group subject to the increase of the load on any pile being not more than 25 percent of the allowable load on a single pile.

8.2.3.11 *Reinforcement*

8.2.3.11.1 The design of the reinforcing cage varies depending upon the driving and installation conditions, the nature of the subsoil and the nature of load to be transmitted by the shaft - axial, or otherwise. The minimum area of longitudinal reinforcement of any type or grade within the pile shaft shall be 0.4 percent of the cross-sectional area of the pile shaft. The minimum reinforcement shall be provided throughout the length of the shaft.

8.2.3.11.2 The curtailment of reinforcement along the depth of the pile, in general, depends on the type of loading and subsoil strata. In case of piles subjected to compressive load only, the designed quantity of reinforcement may be curtailed at appropriate level according to the design requirements. For piles subjected to uplift load, lateral load and moments, separately or with compressive loads, it would be necessary to provide reinforcement for the full depth of pile. In soft clays or loose sands, or where there may be danger to green concrete due to driving of adjacent piles, the reinforcement should be provided to the full pile depth, regardless of whether or not it is required from uplift and lateral load considerations. However, in all cases, the minimum reinforcement specified in **8.2.3.11.1** shall be provided throughout the length of the shaft.

8.2.3.11.3 Piles shall always be reinforced with a minimum amount of reinforcement as dowels keeping the minimum bond length into the pile shaft below its cut-off level and with adequate projection into the pile cap, irrespective of design requirements.

8.2.3.11.4 Clear cover to all main reinforcement in pile shaft shall be not less than 50 mm. The laterals of a reinforcing cage may be in the form of links or spirals. The diameter and spacing of the same is chosen to impart adequate rigidity of the reinforcing cage during its handling and installations. The minimum diameter of the links or spirals shall be 8 mm and the spacing of the links or spirals shall be not less than 150 mm. Stiffner rings preferably of 16 mm diameter at every 1.5 m centre to centre should be provided along the length of the cage for providing rigidity to reinforcement cage. Minimum 6 numbers of vertical bars shall be used for a circular pile and minimum diameter of vertical bar shall be 12 mm. The clear horizontal spacing between the adjacent vertical bars shall be four times the maximum aggregate size in concrete. If required, the bars can be bundled to maintain such spacing.

8.2.3.12 *Design of pile cap*

8.2.3.12.1 The pile caps may be designed by assuming that the load from column is dispersed at 45º from the top of the cap to the mid-depth of the pile cap from the base of the column or pedestal. The reaction from piles may also be taken to be distributed at 45º from the edge of the pile, up to the mid-depth of the pile cap. On this basis the maximum bending moment and shear forces should be worked out at critical sections. The method of analysis and allowable stresses should be in accordance with Part C 'Structural Design/ Section 5 Structural Concrete' of this NBCS.

8.2.3.12.2 Pile cap shall be deep enough to allow for necessary anchorage of the column and pile reinforcement.

8.2.3.12.3 The pile cap should be rigid enough so that the imposed load could be distributed on the piles in a group equitably.

8.2.3.12.4 In case of a large cap, where differential settlement may occur between piles under the same cap, due consideration for the consequential moment should be given.

8.2.3.12.5 The clear overhang of the pile cap beyond the outermost pile in the group shall be a minimum of 150 mm.

8.2.3.12.6 The cap is generally cast over a 75 mm thick levelling course of concrete. The clear cover for main reinforcement in the cap slab shall not be less than 60 mm.

8.2.3.12.7 The embedment of pile into cap should be 75 mm.

8.2.3.13 *Grade beams*

8.2.3.13.1 The grade beams supporting the walls shall be designed taking due account of arching effect due to masonry above the beam. The beam with masonry due to composite action behaves as a deep beam.

For the design of grade beams, a maximum bending moment of $\frac{wl^2}{30}$, where w is uniformly distributed load per metre run and l is the effective span in metres, shall be considered. For considering composite action, the minimum height of wall shall be 0.6 times the pile spacing. The brick strength should not be less than 3 N/mm^2. For concentrated and other loads which come directly over the beam, full bending moment should be considered.

8.2.3.13.2 The minimum overall depth of grade beams shall be 200 mm. An equal amount of reinforcement may be provided at the bottom and top of the beam. The longitudinal reinforcement both at top and bottom should not be less than three bars of 12 mm diameter with clear cover space of 50 mm. Spacing of stirrups of 8 mm diameter bars should not be more than the depth of grade beam.

8.2.3.13.3 In expansive soils, the grade beams and 75 mm levelling concrete course shall be provided over 40 mm down gravel layer/mechanically stabilized mix (MSM) layer having a minimum compacted thickness of 300 mm and minimum width equal to five times the width of grade beams (*see* Fig. 8).

8.2.3.13.4 In the case of exterior beams over piles in expansive soils, plinth protection with proper slope shall be provided.

8.2.4 For detailed information on driven/bored cast *in-situ* concrete piles regarding control of piling, installation, defective pile and recording of data, reference shall be made to good practice [C-2(43)].

8.2.5 *Bored Cast In-Situ Concrete Piles on Rocks*

Design and construction of bored cast *in-situ* piles founded on rocks shall be carried out in accordance with good practice [C-2(41)].

8.2.6 *Non-Destructive Testing*

For quality assurance of concrete piles, non-destructive integrity test may be carried out prior to laying of beam/caps, in accordance with accepted standard [C-2(44)].

8.3 Driven Precast Concrete Piles

8.3.1 Provisions of **8.2** except **8.2.3.11** shall generally apply.

8.3.2 *Design of Pile Section*

8.3.2.1 Design of pile section shall be such as to ensure the strength and soundness of the pile against lifting from the casting bed, transporting, handling and driving stresses without damage.

8.3.2.2 Any shape having radial symmetry will be satisfactory for precast piles. The most commonly used cross-sections are square and octagonal.

8.3.2.3 Where exceptionally long lengths of piles are required, hollow sections can be used. If the final condition requires larger cross-sectional area, the hollow sections may be filled with concrete after driving in position.

8.3.2.4 Wherever, final pile length is so large that a single length precast pile unit is either uneconomical or impracticable for installation, the segmental precast RCC piles with a number of segments using efficient mechanical jointing could be adopted.

Excessive whipping during handling precast pile may generally be avoided by limiting the length of pile to a maximum of 50 times the least width. As an alternative, segmental precast piling technique could be used.

The design of joints shall take care of corrosion by providing additional sacrificial thickness for the joint, wherever warranted.

8.3.2.5 Stresses induced by bending in the cross-section of precast pile during lifting and handling may be estimated as for any reinforced concrete section in accordance with relevant provisions of Part C 'Structural Design/ Section 5 Structural Concrete' of this NBCS. The calculations for bending moment for different support conditions during handling are given in Table 5.

Table 5 Bending Moment for Different Support Conditions (*Clause* 8.3.2.5)

Sl No. (1)	Number of Points of Pick Up (2)	Location of Support From End in Terms of Length of Pile For Minimum Moments (3)	Bending Moment to be Allowed for Design Kn-M (4)
i)	One	0.293 L	4.3 WL
ii)	Two	0.207 L	2.2 WL
iii)	Three	0.145 L, the middle point will be at the centre	1.05 WL

NOTE — W = weight of pile, in kN;

L = length of pile, in m.

8.3.2.6 The driving stresses on a pile may be estimated by the following formula:

$$\frac{\text{Driving resistance}}{\text{Cross}-\text{sectional area of the pile}}\times[\frac{2}{\sqrt{n}}-1]$$

where

n = efficiency of the blow (*see* 8.3.2.6.1 for probable value of n).

NOTE — For the purpose of this formula, cross-sectional area of the pile shall be calculated as the overall sectional area of the pile including the equivalent area for reinforcement.

8.3.2.6.1 The formula for efficiency of the blow, representing the ratio of energy after impact to striking energy of ram, n, is:

where W is greater than $P.e$ and the pile is driven into penetrable ground,

$$\boldsymbol{n} = \frac{\boldsymbol{W} + (\boldsymbol{P}\cdot\boldsymbol{e}^2)}{\boldsymbol{W} + \boldsymbol{P}}$$

where W is less than $P.e$ and the pile is driven into penetrable ground,

$$\boldsymbol{n} = [\frac{\boldsymbol{W}+(\boldsymbol{P}\cdot\boldsymbol{e}^2)}{\boldsymbol{W}+\boldsymbol{P}}] - [\frac{\boldsymbol{W} - (\boldsymbol{P}\cdot\boldsymbol{e})}{\boldsymbol{W} + \boldsymbol{P}}]^2$$

The following are the values of n in relation to e and to the ratio of P/W:

Sl No.	*Ratio of P/W*	*e = 0.5*	*e = 0.4*	*e = 0.32*	*e = 0.25*	*e = 0*
(1)	(2)	(3)	(4)	(5)	(6)	(7)
i)	½	0.75	0.72	0.70	0.69	0.67

iii)	1½	0.55	0.50	0.47	0.44	0.40
iv)	2	0.50	0.44	0.40	0.37	0.33
v)	2½	0.45	0.40	0.36	0.33	0.28
vi)	3	0.42	0.36	0.33	0.30	0.25
vii)	3½	0.39	0.33	0.30	0.27	0.22
viii)	4	0.36	0.31	0.28	0.25	0.20
ix)	5	0.31	0.27	0.24	0.21	0.16
x)	6	0.27	0.24	0.21	0.19	0.14
xi)	7	0.24	0.21	0.19	0.17	0.12
xii)	8	0.22	0.20	0.17	0.15	0.11

NOTES

1 W = mass of the ram, in tonne and P = weight of the pile, anvil, helmet and follower (if any), in tonne.

2 Where the pile finds refusal in rock, $0.5P$ should be substituted for P in the above expressions for n.

3 e is the coefficient of restitution of the materials under impact as tabulated below:

a) For steel ram of double-acting hammer striking on steel anvil and driving reinforced concrete pile, e = 0.5;

b) For cast-iron ram of single-acting or drop hammer striking on head of reinforced concrete pile, e = 0.4;

c) Single-acting or drop hammer striking a well-conditioned driving cap and helmet with hard wood dolly in driving reinforced concrete piles or directly on head of timber pile, e = 0.25; and

d) For a deteriorated condition of the head of pile or of dolly, e = 0.

8.3.3 *Reinforcement*

8.3.3.1 The longitudinal reinforcement of any type or grade shall be provided in precast reinforced concrete piles for the entire length. All the main longitudinal bars shall be of the same length and should fit tightly into the pile shoe, if there is one. Shorter rods to resist local bending moments may be added but the same should be carefully detailed to avoid any sudden discontinuity of the steel which may lead to cracks during heavy driving. The area of main longitudinal reinforcement shall not be less than the following percentages of the cross-sectional area of the piles:

a) For piles with a length less than 30 times the least width: 1.25 percent;

b) For piles with a length 30 to 40 times the least width: 1.5 percent; and

c) For piles with a length greater than 40 times the least width: 1.5 percent.

8.3.3.2 Piles shall always be reinforced with a minimum amount of reinforcement as dowels keeping the minimum bond length into the pile shaft below its cut-off level and with adequate projection into the pile cap, irrespective of design requirements.

8.3.3.3 Clear cover to all main reinforcement in pile shaft shall be not less than 50 mm. The laterals of a reinforcing cage may be in the form of links or spirals. The diameter and spacing of the same is chosen to impart adequate rigidity of the reinforcing cage during its handing and installations. The minimum diameter of the links or spirals shall be 8 mm and the spacing of the links or spirals shall be not less than 150 mm Stiffner rings preferably of 16 mm diameter at every 1.5 m centre to centre to be provided along the length of the cage for providing rigidity to reinforcement cage. Minimum 6 numbers of vertical bars shall be used for a circular pile and minimum diameter of vertical bar shall be 12 mm. The clear horizontal spacing between the adjacent vertical bars shall be four times the maximum aggregate size in concrete. If required, the bars may be bundled to maintain such spacing.

8.3.4 Additional provision for prestressed concrete piles shall be as per good practice [C-2(45)].

8.3.5 For detailed information regarding casting and curing, storing and handling, control of pile driving and recording of data, reference shall be made to good practice [C-2(45)].

8.3.6 *Non-Destructive Testing*

For quality assurance of concrete piles, non-destructive integrity test may be carried out prior to laying of beam/caps, in accordance with good practice [C-2(44)].

8.4 Precast Concrete Piles in Prebored Holes

8.4.1 Provisions of **8.3** except **8.3.3** shall generally apply.

8.4.2 *Handling Equipment for Lowering and Grouting Plant*

Handling equipment such as crane, scotch derricks, movable gantry may be used for handling and lowering the precast piles in the bore. The choice of equipment will depend upon length, mass and other practical requirements.

The mixing of the grout shall be carried out in any suitable high speed colloidal mixer. Normally the colloidal mixer is adequate to fill the annular space with grouts. Where this is not possible, a suitable grout pump shall be used.

8.4.3 *Reinforcement*

8.4.3.1 The design of the reinforcing cage varies depending upon the handling and installation conditions, the nature of the subsoil and the nature of load to be transmitted by the shaft - axial, or otherwise. The minimum area of longitudinal reinforcement of any type or grade within the pile shaft shall be 0.4 percent of the cross-sectional area of the pile shaft or as required to cater for handling stresses (*see* **8.3.2.5**), whichever is greater. The minimum reinforcement shall be provided throughout the length of the shaft.

8.4.3.2 Piles shall always be reinforced with a minimum amount of reinforcement as dowels keeping the minimum bond length into the pile shaft below its cut-off level and with adequate projection into the pile cap, irrespective of design requirements.

8.4.3.3 Clear cover to all main reinforcement in pile shaft shall be not less than 50 mm. The laterals of a reinforcing cage may be in the form of links or spirals. The diameter and spacing of the same is chosen to impart adequate rigidity of the reinforcing cage during its handing and installations. The minimum diameter of the links or spirals shall be 8 mm and the spacing of the links or spirals shall be not less than 150 mm. Stiffner rings preferably of 16 mm diameter at every 1.5 m centre to centre to be provided along length of the cage for providing rigidity to reinforcement cage. Minimum 6 numbers of vertical bars shall be used for a circular pile and minimum diameter of vertical bar shall be 12 mm. The clear horizontal spacing between the adjacent vertical bars shall be four times the maximum aggregate size in concrete. If required, the bars may be bundled to maintain such spacing.

8.4.3.4 A thin gauge sheathing pipe of approximately 40 mm diameter may be attached to the reinforcement cage, in case of solid piles, to form the central duct for pumping grout to the bottom of the bore. The bottom end of the pile shall have proper arrangements for flushing/cleaning for grouting. Air lift technique may be used for cleaning the borehole, however this technique should be used carefully in case of silty and sandy soil.

8.4.4 For detailed information regarding casting and curing, storing and handling, control of pile installation and recording of data, reference shall be made to good practice [C-2(46)].

8.4.5 *Non-Destructive Testing*

For quality assurance of concrete piles, non-destructive integrity test may be carried out prior to laying of beam/caps, in accordance with accepted standard [C-2(44)].

8.5 Under-Reamed Piles

8.5.1 *General*

Under-reamed piles are bored cast *in-situ* and bored compaction concrete types having one or more bulbs formed by suitably enlarging the borehole for the pileshaft. These piles are suited for expansive soils which are often subjected to considerable ground movements due to seasonal moisture variations. These also find wide application in other soil strata where economics are favorable. When the ground consists of expansive soil, for example black cotton soils, the bulb of under-reamed pile provide anchorage against uplift due to swelling pressure, apart from the increased bearing, provided topmost bulb is formed close to or just below the bottom of active zone. Negative slopes may not be stable in certain strata conditions, for example, in pure sands (clean sands with fines less than five per cent) and very soft clayey strata having N of SPT less than 2 (undrained shear strength of less than 12.5 kN/m^2). Hence formation of bulb(s) in such strata is not advisable. In subsoil strata above water table, the maximum number of bulbs in under-reamed pile should be restricted to four. In the strata such as clay, silty clay and clayey silt with high water table where sides of bore hole stand by itself without needing any stabilization by using drilling mud or otherwise, the maximum number of bulbs in under-reamed piles should be restricted to two. In strata for example clayey sand, silty sand and sandy silt with high water table where bore hole needs stabilization by using drilling mud, under-reamed piles with more than one bulb shall not be used. In loose to medium pervious strata such as clayey sand, silty sand and sandy silt strata, compaction under-reamed piles may be used as the process of compaction increases the load carrying capacity of piles. From practical considerations, under-reamed piles of more than 10 m depth shall not be used without ensuring their construction feasibility and load carrying capacity by initial load tests in advance. In view of additional anchorage available with the provision of bulbs, under-reamed piles can be used with advantage to resist uplift loads.

8.5.2 *Materials*

Provisions of 8.2.2 shall generally apply.

8.5.3 *Design Considerations*

8.5.3.1 *General*

Under-reamed pile foundation shall be designed in such a way that the load from the structure they support can be transmitted to the sub-surface with adequate factor of safety against shear failure of sub-surface and without causing such settlement (differential or total) which may result in structural damage and/or functional distress under permanent/transient loading. The pile shaft should have adequate structural capacity to withstand all loads (vertical compression, uplift, lateral) and moments which are to be transmitted to the subsoil and shall be designed according to [C-2(47)].

8.5.3.1.1 In expansive soils, the minimum length of piles shall be 3.5 m below ground level. In case of expansive soil deposits of shallow depth overlying non-expansive competent strata or rock, piles of shorter length can also be provided.

However, in case of high to very high expansive soils, due care shall be taken to establish the minimum depth of pile with the top-most (first) bulb located below the level of significant moisture variations/active zone.

8.5.3.1.2 The diameter of under-reamed bulbs may vary from 2 times to 2.5 times shaft diameter depending upon the feasibility of construction and design requirements. In bored cast *in-situ* under-reamed piles and under-reamed bored compaction piles, the bulb diameter shall be normally 2.5 times and 2 times the shaft diameter, respectively.

8.5.3.1.3 The spacing of bulbs should not be less than 1.5 times the diameter of bulb.

8.5.3.1.4 The first bulb should be at a minimum depth of 2 times the bulb diameter below ground level or cut-off level, whichever is lower.

8.5.3.1.5 Under-reamed piles with more than two bulbs are not advisable without ensuring their feasibility in strata needing stabilization of boreholes by drilling mud. The number of bulbs in case of under-reamed bored compaction piles should not exceed two in such strata.

8.5.3.1.6 The minimum diameter of pile shaft shall be 250 mm. However, in case of strata/ground water consisting of excessive chemicals such as sulphates and chlorides, or piles with tremie concreting, the minimum diameter of the pile shaft shall be 300 mm.

8.5.3.1.7 Under-reamed batter piles in dry soil conditions can be constructed with batter not exceeding 15°.

8.5.3.1.8 The construction feasibility of under-ream/ bulb should be examined as per soil characteristics, particularly in case of clean/river sands.

8.5.3.1.9 For guidance, typical details of bored cast *in-situ* under-reamed pile foundations are shown in Fig. 9.

9B SECTION OF MULTI - UNDER-REAMED PILE

FIG. 9 TYPICAL DETAILS OF BORED CAST IN-SITU UNDER-REAMED PILE FOUNDATION

8.5.3.2 *Safe load*

Safe load on a pile shall be taken as the least of the following:

a) By calculating the ultimate load from soil properties and applying a suitable factor of safety (*see* Annex J);

b) By load test on pile as good practice [C-2(40)]; and

c) From safe load tables.

8.5.3.2.1 *Load test*

Provisions of 8.2.3.3.1.3 shall generally apply.

8.5.3.2.2 In the absence of detailed subsoil investigations and pile load tests for minor and less important structures, a rough estimate of safe load on piles may be made from the safe load table given in the good practice [C-2(48)].

NOTE — Safe loads as given in the above referred Table are symptomatic. Safe load carrying capacity of pile shall be worked out for the actual geotechnical data using 6.2.3.1 of good practice [C-2(48)], subjected to confirmation by initial pile load test in accordance with good practice [C-2(39)] and other provisions in 6.2.3.2 of good practice [C-2(48)].

8.5.3.3 *Negative skin friction or dragdown force*

Provisions of 8.3.4 shall generally apply subject to the condition that the under-reamed bulb is provided below the strata susceptible to negative skin friction.

8.5.3.4 *Structural capacity*

Provisions of **8.3.5** shall generally apply except that the under-reamed pile stem is designed for axial capacity as a short column. Under-reamed piles under lateral loads and moments tend to behave more as rigid piles due to the presence of bulbs and therefore the analysis can be done on rigid pile basis. Nominally reinforced long single bulb piles which are not rigid may be analyzed as per the method given in Annex G or as per other accepted methods.

8.5.3.5 *Spacing*

Generally, the centre to centre spacing for bored cast *in-situ* under-reamed piles in a group should be two times the bulb diameter ($2D_u$). It shall not be less than 1.5 D_u. For under-grade beams, the maximum spacing of piles should generally not exceed 3 m. In under-reamed compaction piles, generally the spacing should not be less than 1.5 D_u. If the adjacent piles are of different diameter, the value of larger bulb diameter shall be considered for spacing.

8.5.3.6 *Pile groups*

In order to determine the load-carrying capacity of a group of piles, a number of efficiency equations are in use. However, it is difficult to establish the accuracy of these efficiency equations as the behaviour of pile group is dependent on many complex factors. It is desirable to consider each case separately on its own merits.

The load-carrying capacity of a pile group may be equal to or less than the load-carrying capacity of individual piles multiplied by the number of piles in the group.

In load bearing walls, piles should generally be provided under all wall junctions to avoid point loads on beams.

8.5.3.7 *Transient and overloading*

Provisions of **8.2.3.9** and **8.2.3.10** shall generally apply.

8.5.3.8 *Reinforcement*

8.5.3.8.1 The minimum area of longitudinal reinforcement shall be 0.4 percent of the cross-sectional area of the pile shaft and shall be provided throughout the length.

8.5.3.8.2 The main reinforcement of the pile shall extend above cut-off level for at least the development length to be embedded into the pile cap/grade beam.

8.5.3.8.3 The minimum diameter of the rings shall be 8 mm and the spacing of the rings shall be not less than 150 mm. Stiffener rings of suitable diameter and spacing should be provided in the reinforcing cage to impart adequate rigidity to the reinforcing cage during handling and installation. Stiffener rings preferably of 12 mm diameter at every 1.5 m centre to centre spacing should be provided along the entire length of the cage. Minimum 6 numbers of vertical bars shall be used for a circular pile and minimum diameter of vertical bar shall be 12 mm. The minimum clear horizontal spacing between the adjacent vertical bars shall be four times the maximum aggregate size in concrete. If required, the bars can be bundled to maintain such spacing.

8.5.3.8.4 Clear cover to all reinforcement including rings in pile shaft shall be not less than 50 mm, which shall be increased to 75 mm in case of aggressive environment of sulphates, etc. In addition, the clear cover of the main reinforcement from the pile tip shall be 75 mm to 100 mm.

8.5.3.9 The design of pile cap and grade beams shall conform to the requirements specified in **8.2.3.12** and **8.2.3.13** respectively.

8.5.4 For detailed information on under-reamed piles regarding control of pile, installation, reference shall be made to good practice [C-2(46)].

8.5.5 *Non-Destructive Testing*

For quality assurance of concrete piles, non-destructive integrity test may be carried out prior to laying of beam/caps, in accordance with accepted standard [C-2(44)].

8.6 Timber Piles

8.6.1 *General*

Piles find application in foundations to transfer loads from a structure to competent sub-surface strata having adequate load-bearing capacity. The load transfer mechanism from a pile to the surrounding ground is complicated and is not yet fully understood, although application of pile foundations is in practice over many decades. Broadly, piles transfer axial loads either substantially by friction along its shaft and/or by the end bearing. Piles are used where either of the above load transfer mechanism is possible depending upon the subsoil stratification at a particular site. Construction of pile foundation requires a careful choice of piling system depending upon the subsoil conditions, the load characteristics of the structure and the limitations of total settlement, differential settlement and any other special requirement of a project. The installation of piles demands careful control on position, alignment and depth and involves specialized skill and experience.

Timber piles, currently do not find extensive use in civil engineering works, however, these piles have been used for compaction of soils, for supporting and protecting water-front structures and also as pile foundations. The choice for using a timber pile is mainly governed by the availability of good quality structural timber, site conditions, particularly the water-table conditions. Timber piles, however, should be avoided because of two reasons, (a) to preserve the environment and green vegetative cover and (b) at most of the places in India, water table has gone down substantially which implies that the timber pile will be only partially under water and this condition is highly undesirable for durability of timber.

Use of treated or untreated piles will depend upon the site conditions and upon whether the work is of permanent or of temporary nature. The timber pile installed should have its entire length embedded under water so that the pile may not get deteriorated. They have the advantages of being comparatively light for their strength and are easily handled. However, they will not withstand as hard driving as steel or concrete piles. Timber has to be selected carefully and treated where necessary for use as piles, as the durability and performance would considerably depend upon the quality of the material and relative freedom from natural defects. If the piles are perennially under salt water condition, treatment of timber is not necessary since by immersion in salt water the life of the pile will be very long. Timber piles are generally used for single and two storeyed structures in back water area where bearing strata is available at a depth less than 12 m. Coconut/Palmyra tree trunks have also been used as timber piles in coastal areas.

8.6.2 *Materials*

8.6.2.1 *Timber*

The timber shall have the following characteristics:

a) Only structural timber shall be used for piles (*see* Part C 'Structural Design/Section 3 Timber and Bamboo, 3(A) Timber' of this NBCS);

b) The length of an individual pile shall be,

   1) the specified length ± 300 mm for piles up to and including 12 m in length; and

   2) the specified length ± 600 mm for piles above 12 m in length.

c) The ratio of heartwood diameter to the pile butt diameter shall be not less than 0.8; and

d) Piles to be used untreated shall have as little sapwood as possible.

8.6.3 *Design Considerations*

8.6.3.1 *General*

Pile foundations shall be designed in such a way that the load from the structure can be transmitted to the sub-surface with adequate factor of safety against shear failure of sub-surface and without causing such settlement, (differential or total), which may result in structural damage and/or functional distress under permanent/transient loading. The pile shaft should have adequate structural capacity to withstand all loads (vertical, lateral or otherwise) which are to be transmitted to the subsoil.

8.6.3.2 *Adjacent structures*

When working near existing structures, care shall be taken to avoid damage to such structures. In case of deep excavations adjacent to piles, proper shoring or other suitable arrangement shall be made to guard against undesired lateral movement of soil. Good practice [C-2(39)] may be used as a guide for studying qualitatively the effect of vibration on persons and structures.

8.6.3.3 *Pile capacity*

See **8.2.3.3**.

8.6.3.4 *Structural capacity*

8.6.3.4.1 The pile shall have necessary structural strength to transmit the loads imposed on it, ultimately to the soil. The structural capacity of the timber piles shall be based on the permissible compressive stress of the timber species.

8.6.3.4.2 The length of pile projected into the pile cap is critical for ensuring lateral load transfer and pull-out resistance. Effective transfer of lateral load may be possible with 100 mm to 200 mm projection into the pile cap concrete depending on the safe lateral load capacity. However, pull-out resistance that can be developed by such small penetration may be limited and the use of timber piles for resisting pull-out resistance may not be viable.

8.6.3.4.3 It is preferable to conduct an initial load test as given in good practice [C-2(40)] to assess the axial capacity, lateral capacity and pull-out capacity of piles. For compaction piles, tests should be done on a group of piles with the cap resting on the ground. The acceptance criteria shall also be as per the provisions given in good practice [C-2(40)]

8.6.3.5 For detailed information on timber piles regarding spacing, classification, control of pile driving, storing and handling, reference shall be made to good practice [C-2(49)].

9 DESIGN AND CONSTRUCTION OF COMBINED PILED RAFT FOUNDATIONS

9.1 General

This clause covers the design and construction of combined piled raft foundation (CPRF) for residential, commercial and industrial structures, tall structures, store houses, storage tanks, etc. The CPRF transmits the load to soil by resistance developed by the components of the foundation, that is, piles and raft, the raft being placed on competent ground. The piles develop resistance along the pile shaft by skin friction and at the pile tip by end bearing. The raft develops the resistance by generating the contact pressure below the raft.

CPRF shall not be used in cases where soil layers of relatively low stiffness (For example, very soft cohesive soil, organic soil, collapsible soil, liquefiable soil) are situated closely beneath the raft. Provisions of this standard shall not be applicable to layered soil with significantly high stiffness (modulus) contrast between the top and bottom layers.

9.2 Necessary Information

For satisfactory design and construction of a combined pile-raft foundation, the following information is necessary:

a) Details of site plan showing location of proposed and adjacent structures;

b) Details of plan and vertical cross-section of the proposed building with position of beam and columns;

c) Different load combinations and their intensity indicating design loads, preferably shown in schematic plan;

d) All the loads due to seismic, wind and water current, etc indicated separately;

e) Limiting values of performance parameters, such as allowable bearing pressure, allowable total settlement, allowable differential settlement, allowable angular distortion, that the foundation and superstructure can withstand;

f) Information on geological history, seismicity, seasonal variation of ground water, climatic factors, for example, sudden flooding, erosion, etc;

g) The design and construction of CPRF requires rigorous geotechnical investigations by using both field and laboratory techniques. The proper dimensioning of CPRF will purely depend up on the outcome of geotechnical investigations. The data obtained from the both the investigations, that is, preliminary investigation for feasibility study and detailed investigation for analyses and design shall be analysed by geotechnical experts;

h) *Geotechnical information* — Sub-surface profile with stratification details, engineering and index properties of founding media to be in accordance with good practice [C-2(8)] and [C-2(50)] and other relevant standards which are essential for the design of CPRF system. Any supplementary investigations should be carried out to obtain additional geotechnical information for design of CPRF;

j) *Extent of geotechnical investigations* — The structure and properties of the substrata and the groundwater conditions shall be known in sufficient detail for any piled-raft construction project. This is necessary to reliably assess the stability and serviceability of the pile and piled-raft foundations and of the overall structure as required by relevant Indian Standards and to assess the effects of foundations on their surroundings. The geotechnical investigations shall extend to sufficient depth below pile tip to record all ground formations and strata influencing the structure and its execution and to identify the load-bearing and deformation properties of the ground. The geotechnical investigations shall be in accordance with good practice [C-2(8)] and [C-2(50)];

k) The geotechnical investigation report and the geotechnical design report, respectively, shall contain all relevant data that can affect CPRF capacity, choice of the execution method and the pile installation. Design soil parameters shall be derived for the CPRF system. The ground information and the parameters related not only to pile capacity, but also to drilling ability, drivability, etc shall be provided;

m) The results of field test on single piles (both ultimate capacity and load- displacement curve). Static test as initial test can be used for design of CPRF, whereas dynamic test is not essential for CPRF design. Dynamic test may be used for additional check, if necessary, on later stage, but not directly related to CPRF design;

n) Dynamic properties of founding media to be taken from geotechnical investigation report; and

p) A review of performance of CPRF in similar locality or ground conditions, if available.

9.3 Design Considerations for Static Load

9.3.1 *General Design Considerations*

9.3.1.1 The design of CPRF should consider the following criteria:

a) Fluctuation in the water table condition and long-term stability of the bearing strata;

b) Consideration for handling sensitive clays and loose bearing soils;

c) Effect of soil excavations;

d) The soil stratigraphy shall be considered when calculating pile responses in the CPRF system;

e) Differential movement of the foundations between the old and new structures;

f) Wherever possible, the centre area of the foundation should be located directly beneath the centre of gravity of the imposed load or else effect of eccentricity should be considered;

g) The load carrying capacity of the combined system subjected to vertical, lateral and moment loadings, total and differential settlement; and

h) Some of the key design considerations are:

    1) Load carrying capacity of the combined system at the desired settlement level for vertical, lateral and moment loadings;

2) Maximum settlement;
3) Differential settlement;
4) Raft moments and shears for the structural design of the raft; and
5) Pile loads and moments, for the structural design of the piles.

9.3.2 *Stages of CPRF Design*

9.3.2.1 The three main stages of CPRF design are:

a) *Preliminary Stage* (*Feasibility Study*) — Assessment of the performance of raft without piles that includes estimation of vertical and lateral bearing capacity and the settlements. Assessment of the feasibility of using a pile raft and the required number of piles to satisfy the design requirement;

b) *General Pile Characteristics* (*Preliminary Design Stage*) — Pile should be designed for the combined resistances; and

c) *Final Detailed Design* — Final detailed design to obtain the number of piles, location and configuration, settlement, bending moment and shear forces in raft and the pile loads and moments.

9.3.3 *Design Steps*

Design philosophy is illustrated in Fig. 10 and the subsequent design steps to be followed are given in **9.3.3.1** to **9.3.3.5**, **9.3.4** and **9.3.5**.

9.3.3.1 The static pile formula based on the ground parameters of good practice [C-2(51)] can be used for estimation of ultimate load capacity of piles. The provision made in good practice [C-2(52)] as applicable should be followed for the design and construction of piles unless otherwise stated. The procedure for pile load testing should be as per good practice [C-2(40)]. Information obtained (load-settlement response) from pile load test shall be interpreted by geotechnical engineer to arrive at the allowable load with reference to a particular settlement. Pile loads and moment for the structural design of the piles should be considered.

9.3.3.2 The stability and capacity of raft based on the ground parameters as per good practice [C-2(34)] and [C-2(53)] can be estimated. The provision made in good practice [C-2(53)] should be followed for the design and construction of raft foundation unless otherwise stated. For estimation of raft settlement, the guidance given in good practice [C-2(54)] may be used. However, the calculation of settlement for entire CPRF system will be different as described in subsequent section of this standard. Raft moment and shear forces for structural design of raft should be considered.

9.3.3.3 The following are the design philosophies:

a) *Conventional Approach* — Piles are designed as a group while making some allowances for contribution of the raft, primarily to load carrying capacity;

b) *Settlement Control Approach* — Piles are placed strategically below the raft in order to reduce the total and differential settlement. However differential settlement reduction is more important than to reduce the overall average settlement; and

c) *Creep Piling Approach* — Piles are designed to operate at a working load at which significant creep starts to occur at some fraction, typically 70 percent to 80 percent, of the ultimate load capacity.

9.3.3.3.1 For CPRF, the design philosophy is generally governed by settlement control approach to meet the serviceability criteria.

9.3.3.4 The vertical load carrying capacity (Q_{CPRF}) of CPRF should be calculated as per Annex K.

9.3.3.5 Dimensionless factors for CPRF design with practical range of parameters are given in Table 6. This guideline should ensure the complete behavioural mechanism of CPRF system.

Table 6 Dimensionless Factors for Combined Piled Raft Foundations

(*Clause* 9.3.3.5)

Sl No.	Dimensionless Factors	Definition	Practical Range
(1)	(2)	(3)	(4)
i)	Pile slenderness ratio	L_p/D_p	10 to 100
ii)	Pile spacing ratio	S_p/D_p	2.5 to 8
iii)	Pile-soil stiffness ratio	$K_{ps} = E_p/E_s$	100 to 10 000
iv)	Raft plan aspect ratio	L_r/B_r	1 to 10
v)	Raft-soil stiffness ratio	$K_{rs} = \frac{4E_r B_r t_r^3(1-\vartheta_s^2)}{3\pi E_s L_r^4(1-\vartheta_r^2)}$	0.001 to 10

where

B_r = width of the raft;

D_p = diameter of the pile;

E_p = elastic modulus of pile material;

E_r = elastic modulus of raft material;

E_s = elastic modulus of soil;

L_p = length of the pile;

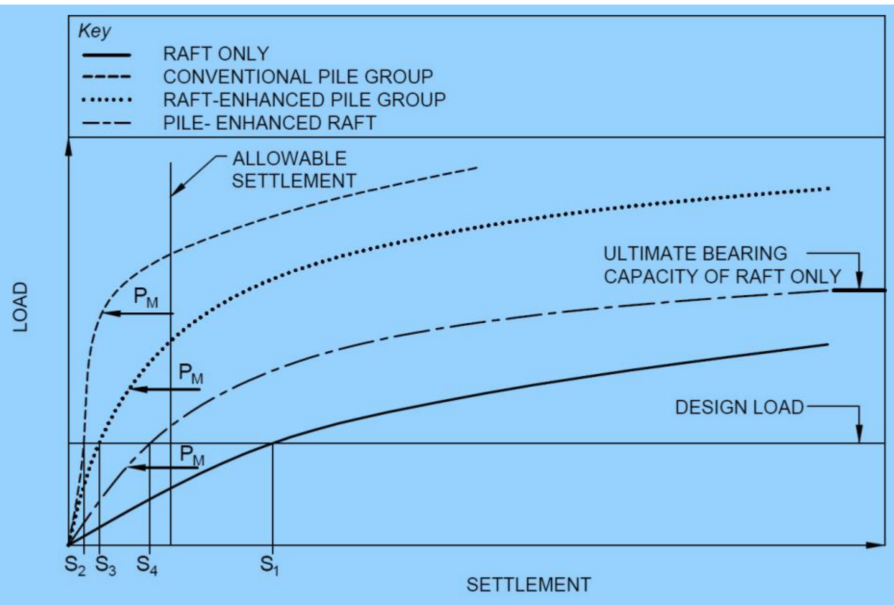
L_r = length of the raft;

S_p = spacing between the piles;

t_r = thickness of raft;

ϑ_r = poisson’s ratio of raft material; and

ϑ_s = poisson’s ratio of soil.



where
P_M = Pile capacity fully mobilized; and
S_1,S_2, etc = Settlement for raft, pile group, etc

FIG. 10(A) LOAD-SETTLEMENT BEHAVIOUR OF RAFTS, CONVENTIONAL PILE GROUPS AND DIFFERENT TYPES OF CPRF

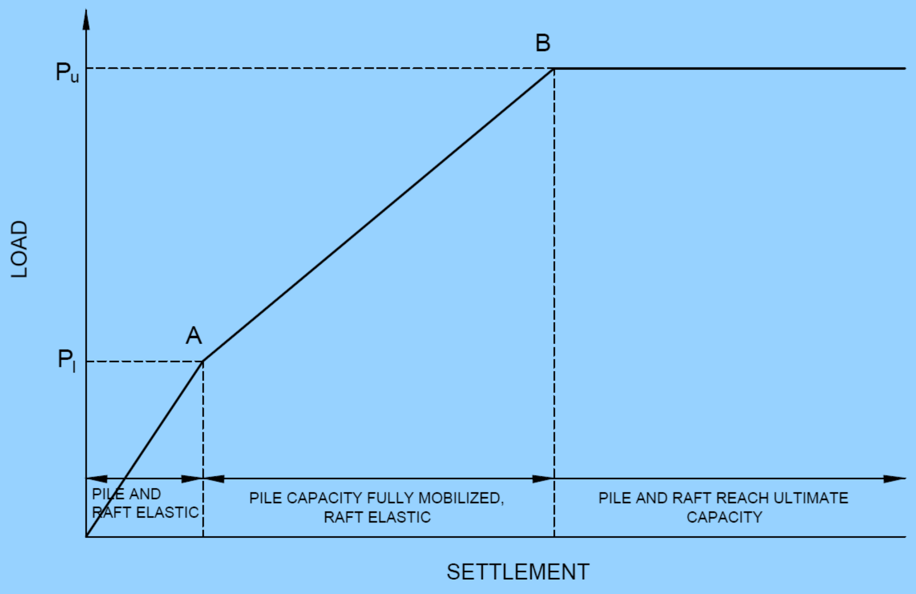


FIG.10(B) SIMPLIFIED LOAD SETTLEMENT CURVE OF A CPRF

FIG. 10 LOAD-SETTLEMENT BEHAVIOUR OF A CPRF

9.3.4 *Computational Model*

Analysis of CPRF shall be performed using computational model which will be able to simulate the appropriate behaviour of single pile. Later from the actual field test results on single pile, the computational model needs to be revised. The computational model shall capture all the interactions as mentioned in Fig. 2(A). Also, the superstructure effect shall be considered appropriately as shown in Fig. 11(A). The two features of estimating the stiffness of soil-pile-raft system are through estimation of pile spring stiffness and raft-soil spring stiffness. The iterative process of convergence of pile and raft response (if implicit) will only come after that. Fig. 11 presents the design model of CPRF system considering soil-pile-raft stiffness. Different values of pile stiffness can occur within a group of piles, depending on their position and on the relative stiffness of the raft.

9.3.4.1 *Estimation of pile spring stiffness*

Stiffness of spring representing the pile shall be estimated by dividing the load carried by pile top element in respective direction with the corresponding top displacement of the pile.

$$\text{Pile spring stiffness, } K_p = \frac{\text{Normal contact force at nodes}}{\text{Nodal displacement}}$$

9.3.4.2 *Estimation of raft-soil spring stiffness*

The soil spring stiffness shall be estimated from the load deformation behaviour of the founding medium as given below:

$$\text{Raft-soil Spring stiffness, } K_r = \frac{\text{Normal contact force at nodes}}{\text{Nodal displacement}}$$

9.3.5 *Allowable Settlement for Static Design Consideration*

For CPRF system, total settlement under gravity load should be restricted within 125 mm and the maximum angular distortion of raft as 1/500. There are four angular distortions (θ_{IL}, θ_{IIL}, θ_{IB} and θ_{IIB}) (Fig. 1) and maximum of these four angular distortions will govern CPRF design for Serviceability Limit State (SLS). The total settlement under gravity load may be taken only as a guide and the permissible total settlement should be decided as per serviceability criteria to fulfil the load sharing mechanism of CPRF system.

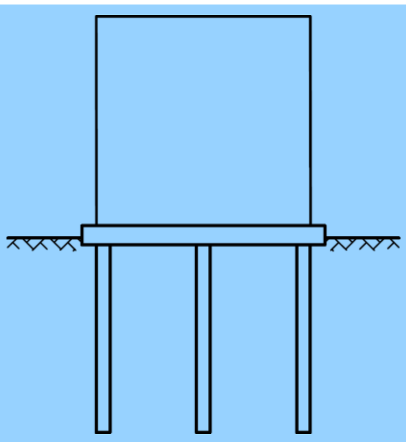

FIG. 11(A) RAFT–PILE–SOIL IN A CPRF

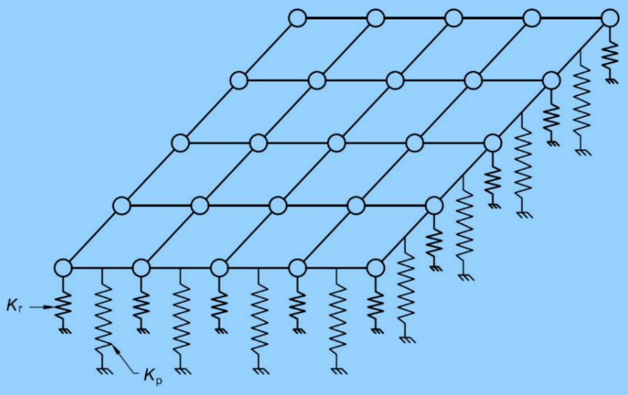

FIG.11(B) PILE AND RAFT-SOIL SPRINGS

FIG. 11 COMBINED ACTION OF SOIL-PILE SYSTEM (TYPICAL DESIGN MODEL)

9.4 Proof of Design and Construction of a CPRF

The examination of the design and the construction of a CPRF with respect to the geotechnical engineering aspects should be controlled by a geotechnical expert particularly qualified on this subject. This includes the construction for piles and deciding the foundation level. The protocols of the acceptance procedure and the measured values have to be included into the examination. The following aspects shall be considered:

a) Critical review of the soil investigation report (field and laboratory tests), including the selection of input parameters;

b) Evaluation of the computational model used for the design of the CPRF and the computation results by using independent comparative calculations. Apart from the independent comparative calculations, additional quality assurance measures in design should be ensured;

c) Assessment of the effects on the adjacent structures; and

d) Examination of the field monitoring (measuring) program within the construction process of the CPRF.

9.5 Monitoring of a CPRF

The load-settlement behaviour and the load transfer within a CPRF should be monitored for further use by a geotechnical expert. The monitoring comprises of geotechnical and geodetic measurements at the new building and also at the adjacent buildings for settlement. The monitoring of the contact pressure at the level of raft, axial load in selected piles, settlement at the level of raft, ground water table and pore-pressure may be adopted for important projects. The monitoring of a CPRF is an elementary and indispensable component of the safety concept and should be used for the following purposes:

a) Observational method should be followed for monitoring of the response of CPRF both during and post construction phases for projects of high importance;

b) Verification of the computational model and the computational approaches;

c) Detection of possible critical conditions in CPRF system;

d) Examination of the quality assurance during the construction and post construction process; and

e) Examination of distribution of loads may be implemented on piles in centre and edges to capture soil-pile-raft interactions.

The monitoring program should be designed by a geotechnical expert during the design phase depending on importance of the project, complexity of the ground condition and long-term performance. Summary of desired instrumentations and their locations should be highlighted in plan as well as sectional view of the foundation layout.

9.6 Structural Design

The general provision for load, shrinkage, creep and temperature effects and provision of design, reinforcement and detailing shall conform to good practice [C-2(47)] and other relevant standards.

9.7 Seismic Design

Design of the CPRF system considering the seismicity of the ground and entire structure and sub-structural system should be handled by experts to ensure conformity to various relevant standards. Both inertial and kinematic effects should be considered in the seismic design.

10 OTHER FOUNDATIONS, SUBSTRUCTURES AND FOUNDATIONS FOR SPECIAL STRUCTURES

10.1 Pier Foundations

10.1.1 *Design Considerations*

10.1.1.1 *General*

The design of concrete piers shall conform to the requirements for columns specified in Part C 'Structural Design/ Section 5 Structural Concrete' of this NBCS. If the bottom of the pier is to be belled so as to increase its load carrying capacity, such bell shall be at least 300 mm thick at its edge. The sides shall slope at an angle of not less than 60° with the horizontal. The least permissible dimensions shall be 600 mm, irrespective of the pier being circular, square or rectangular. Piers of smaller dimensions if permitted shall be designed as piles (*see* **8**).

10.1.1.2 *Plain concrete piers*

The height of the pier shall not exceed 6 times the least lateral dimension. When the height exceeds 6 times the least lateral dimension, buckling effect shall be taken into account, but in no case shall the height exceed 12 times the least lateral dimension.

When the height exceeds 6 times the least lateral dimension, the deduction in allowable stress shall be given by the following formula:

$$f_c' = f_c \ (1.3 - \frac{H}{20D})$$

where

f_c' = reduced allowable stress;

f_c = allowable stress;

D = least lateral dimension; and

H = height of pier.

NOTE — The above provision shall not apply for piers where the least lateral dimension is 1.8 m or greater.

10.1.1.3 *Reinforced concrete piers*

When the height of the pier exceeds 18 times its least dimension, the maximum load shall not exceed:

$$P' = P\,(1.5 - \frac{H}{36D})$$

where

D = least lateral dimension;

H = height of the pier measured from top of bell, if any, to the level of cut-off of pier;

P' = permissible load; and

P = permissible load when calculated as axially loaded short column.

10.2 Design and construction of machine foundations, diaphragm walls, etc, shall be carried out in accordance with good practice [C-2(55)].

11 GROUND IMPROVEMENT

11.1 In poor and weak subsoils, the design of conventional foundation for structures and equipment may present problems with respect to both sizing of foundation as well as control of foundation settlements. A viable alternative in certain situations, is to improve the subsoil to an extent such that the subsoil would develop an adequate bearing capacity and foundations constructed after subsoil improvement would have resultant settlements within acceptance limits. This method/technique is called ground improvement which is used to improve *in-situ* soil characteristics by improving its engineering performance as per the project requirement by altering its natural state, instead of having to alter the design in response to the existing ground limitations. The improvement is in terms of increase in bearing capacity, shear strength, reducing settlement and enhancing drainage facility, mitigating liquefaction potential, etc, of soil, as also in improving lateral capacity in case of deep foundations.

11.2 For provisions with regard to necessary data to be collected to establish the need for ground improvement at a site; considerations for establishing need for ground improvement methods; selection of ground improvement techniques; equipment and accessories for ground improvement; control of ground improvement works and recording of data, reference shall be made to accepted standard [C-2(56)]. Annex L presents various methods of ground improvement along with principles, applicability to various soil conditions, material requirements, equipment required, results likely to be achieved and limitations. This table may be referred to as guidance for selecting the proper method for a situation. *See also* accepted standard [C-2(56)] for details.

11.2.1 For provisions relating to ground improvement by reinforcing the ground using stone columns so as to meet the twin objective of increasing the bearing capacity with simultaneous reduction of settlements, reference shall be made to accepted standard [C-2(57)].

11.2.2 Whenever soft cohesive soil strata underlying a structure are unable to meet the basic requirements of safe bearing capacity and tolerable settlement, ground improvement is adopted to make it suitable for supporting the proposed structure. Both the design requirements that is shear strength and settlement under loading, can be fulfilled by consolidating the soil by applying a preload, if necessary, before the construction of the foundation. This consolidation of soil is normally accelerated with the use of vertical drains. For provisions relating to ground improvement by preconsolidation using vertical drains, reference shall be made to accepted standard [C-2(58)].

11.2.3 Use of suitable geo-synthetics/geo-textiles may be made in an approved manner for ground improvement, where applicable; *see also* accepted standards [C-2(59)].

12 GEOTECHNICAL INSTRUMENTATION

12.1 Geotechnical instrumentation is essential for monitoring the behaviour of soil, rock and structures in civil engineering projects, ensuring safety and design performance. A variety of instruments are deployed at specific locations, where they can provide critical data for various purposes. The data gathered from these instruments allows engineers to assess risks, verify design assumptions and implement corrective actions if necessary.

The typical list of geotechnical instruments, but not limited to these, along with their objectives, is provided in Table 7.

Table 7 Typical List of Geotechnical Instrumentation
(*Clause* 12.1)

Sl No. (1)	Instrumentation (2)	Objective (3)	Applicable for (4)
i)	Inclinometers	Measurement of lateral deflections	Deflection monitoring of deep excavations, shoring systems, landslide/slope movements, lateral load test on piles
ii)	Piezometers	Measurement of underground water pressure (pore water pressure)	To monitor groundwater conditions
iii)	Vibration monitors (Seismographs)	To monitor vibrations due to various construction activities	Monitoring of adjacent critical structures during general construction, demolition, pile driving, blasting etc.
iv)	Strain gauges	To measure strain in structural elements	Strain (force) measurement in pile foundations, struts

Table 7 (*Concluded*)

Sl No. (1)	**Instrumentation** (2)	**Objective** (3)	**Applicable for** (4)
v)	Load cells	To measure loads in various structural elements	Load measurement in rock bolts, foundation anchors, struts, pile foundation during load testing
vi)	Pressure pads/Pressure cells	monitoring long-term pressure imposed by soil on the foundation element	For embankments, rafts, retaining walls,
vii)	Extensometer	Deformation measurement	Measurement of deformation of soil, rock, or can be used during testing of pile foundation to measure deformation of piles at various levels
viii)	Permanent settlement markers	Settlement monitoring	Can be used for monitoring of settlement/ deflections of various structures such as raft, retaining system, slopes, etc.
ix)	Crackmeters	Measure displacement	To measure plate displacement during bi-directional static load test (BDSLT)

ANNEX A

(*Clauses* 7.4.1.11 *and* B-3.3)

DETERMINATION OF MODULUS OF ELASTICITY (E_s) AND POISSONS'S RATIO (μ)

A-1 DETERMINATION OF MODULUS OF ELASTICITY(E_s)

The modulus of elasticity is a function of composition of the soil, its void ratio, stress history and loading rate. In granular soils it is a function of the depth of the strata, while in cohesive soil it is markedly influenced by the moisture content. Due to its great sensitivity to sampling disturbance, accurate evaluation of the modulus in the laboratory is extremely difficult. For general cases, therefore, determination of the modulus may be based on field tests (*see* **A-2**). Where properly equipped laboratory and sampling facility is available, E_s may be determined in the laboratory (*see* **A-3**).

A-2 FIELD DETERMINATION

A-2.1 The value of E_s shall be determined from plate load test in accordance with accepted standard [C-2(9)].

$$E_s = qB\frac{(1-\mu^2)}{s}I_w$$

where

B = least lateral dimension of test plate;

influence ratio;

I_w = 0.82 for a square plate;

1.00 for a circular plate;

q = intensity of contact pressure;

s = settlement; and

μ = poisson's ratio

NOTE — While this procedure may be adequate for light or less important structures under normal conditions, relevant laboratory tests or field tests are essential in the case of unusual soil types and for all heavy and important structures. Plate load test, though useful in obtaining the necessary information about the soil with particular reference to design of foundation has some limitations. The test results reflect only the character of the soil located within a depth of less than twice the width of the bearing plate. Since the foundations are generally larger than the test plates, the settlement and shear resistance will depend on the properties of a much thicker stratum. Moreover, this method does not give the ultimate settlements particularly in case of cohesive soils. Thus, the results of the test are likely to be misleading, if the character of the soil changes at shallow depths, which is not uncommon. A satisfactory load test should, therefore, include adequate soil exploration {*see* good practice [C-2(8)]} with due attention being paid to any weaker stratum below the level of the footing. Another limitation is the concerning of the effect of size of foundation. For clayey soils the bearing capacity (from shear consideration) for a larger foundation is almost the same as that for the smaller test plate. But in dense sandy soils the bearing capacity increases with the size of the foundation. Thus, tests with smaller size plate tend to give conservative values in dense sandy soils. It may, therefore, be necessary to test with plates of at least three sizes and the bearing capacity results extrapolated for the size of the actual foundation (minimum dimensions in the case of rectangular footings).

A.2.1.1 The average value of E_s shall be based on a number of plate load tests carried out over the area, the number and location of the tests, depending upon the extent and importance of the structure.

A-2.1.2 *Effect of Size*

In granular soils the value of E_s corresponding to the size of the raft shall be determined as follows:

$$E_s = E_p \frac{B_f}{B_p} \left[\frac{B_f + B_p}{2B_f} \right]^2$$

Where B_f, B_p represent sizes of foundation and plate and E_p is the modulus determined by the plate load test.

A-2.2 For stratified deposits or deposits with lenses of different materials, results of plate load test will be unreliable and static cone penetration tests may be carried out to determine E_s.

A-2.2.1 Static cone penetration tests shall be carried out in accordance with accepted standard [C-2(41)]. Several tests shall be carried out at regular depth intervals up to a depth equal to the width of the raft and the results plotted to obtain an average value of E_s.

A-2.2.2 The value of E_s may be determined from the following relationship:

$$E_s = 2\, C_{kd}$$

where C_{kd} = cone resistance, in kN/m^2

A-3 LABORATORY DETERMINATION OF E_S

A-3.1 The value of E_s shall be determined by conducting triaxial test in the laboratory in accordance with accepted standard [C-2(60)] on samples collected with least disturbances.

A-3.2 In the first phase of the triaxial test, the specimen shall be allowed to consolidate fully under an all-round confining pressure equal to the vertical effective overburden stress for the specimen in the field. In the second phase, after equilibrium has been reached, further drainage shall be prevented and the deviator stress shall be increased from zero value to the magnitude estimated for the field loading condition. The deviator stress shall then be reduced to zero and the cycle of loading shall be repeated.

A-3.3 The value of E_s shall be taken as the tangent modulus at the stress level equal to one-half the maximum deviator stress applied during the second cycle of loading.

ANNEX B

(*Clauses* 7.4.1.11 *and* C-3)

DETERMINATION OF MODULUS OF SUB-GRADE REACTION

B-1 GENERAL

B-1 The modulus of subgrade reaction (k) as applicable to the case of load through a plate of size 300 mm × 300 mm or beams 300 mm wide on the soils is given in Table 8 for cohesionless soils and in Table 9 for cohesive soils. Unless more specific determination of k is done (*see* **B-2** and **B-3**), these value may be used for design of raft foundation in cases where the depth of the soil affected by the width of the footing may be considered isotropic and the extrapolation of plate load test results is valid.

B-2 FIELD DETERMINATION

B-2.1 In cases where the depth of the soil affected by the width of the footing may be considered as isotropic, the value of k may be determined in accordance with accepted standard [C-2(10)]. The test shall be carried out with a plate of size not less than 300 mm.

B-2.2 The average value of k shall be based on a number of plate load tests carried out over the area, the number and location of the tests depending upon the extent and importance of the structure.

B-3 LABORATORY DETERMINATION

B-3.1 For stratified deposits or deposits with lenses of different materials, evaluation of k from plate load test will be unrealistic and its determination shall be based on laboratory tests {*see* good practice [C-2(60)]}.

B-3.2 In carrying out the test, the continuing cell pressure may be so selected as to be representative of the depth of the average stress influence zone (about 0.5 B to B).

B-3.3 The value of k shall be determined from the following relationship:

$$k = 0.65 \times \sqrt[12]{\left(\frac{E_s B^4}{EI}\right)} \cdot \frac{E_s}{(1-\mu^2)} \cdot \frac{1}{B}$$

where

B = width of the footing;
E = young's modulus of foundation material;
E_s = modulus of elasticity of soil (*see* Annex A);
I = moment of inertia of the foundation; and
μ = poisson's ratio of soil.

B-4 CALCULATIONS

When the structure is rigid (*see* Annex C), the average modulus of subgrade reaction may also be determined as follows:

$$k_s = \frac{\text{Average contact pressure}}{\text{Average settlement of the raft}}$$

Table 8 Modulus of Subgrade Reaction (*k*) for Cohesionless Soils

(*Clause* B-1)

Sl No.	Soil Characteristic		Modulus of Subgrade Reaction (*k*)[1] kN/m³	
	Relative Density	Standard Penetration Test Value (N) (Blows per 300 mm)	For Dry or Moist State	For Submerged State
(1)	(2)	(3)	(4)	(5)
i)	Loose	< 10	15 000	9 000
ii)	Medium	10 to 30	15 000 to 47 000	9 000 to 29 000
iii)	Dense	30 and over	47 000 to180 000	29 000 to 108 000

Table 9 Modulus of Subgrade Reaction (*k*) for Cohesive Soils

(*Clause* B-1)

Sl No.	Soil Characteristic		Modulus of Subgrade Reaction (*k*)[1] kN/m³
	Consistency	Unconfined Compressive Strength kN/m²	
(1)	(2)	(3)	(4)
i)	Stiff	100 to 200	27 000
ii)	Very stiff	200 to 400	27 000 to 54 000
iii)	Hard	400 and over	54 000 to 108 000

---

[1] The above values apply to a square plate 300 mm × 300 mm or beams 300 mm wide.

[1] The values apply to a square plate 300 mm × 300 mm. The above values are based on the assumption that the average loading intensity does not exceed half the ultimate bearing capacity.

ANNEX C

(*Clauses* 7.4.4.1.2 (a), (b), 7.4.4.2 *and* B-4)

RIGIDITY OF SUPERSTRUCTURE AND FOUNDATION

C-1 DETERMINATION OF THE RIGIDITY OF THE STRUCTURE

The flexural rigidity *EI* of the structure of any section may be estimated according to the relation given below (*see also* Fig. 12)

$$EI = \frac{E_1 I_i b^2}{2H^2} + \sum \; E_2\, I_b \left[1 + \frac{(I_u{}' + I_1{}')b^2}{(I_b{}' + I_u{}' + I_f{}')l^2}\right]$$

where

b = length or breadth of the structure in the direction of bending, in m;

E_1 = modulus of elasticity of the infilling material (wall material), in kN/m^2;

E_2 = modulus of elasticity of the frame material, in kN/m^2;

H = total height of the infilling, in m;
h_1 = length of the lower column, in m;
h_u = length of the upper column, in m;
I_b = moment of inertia of the beam, in m^4;
$I_b{}'$ = $\frac{I_b}{l}$;
$I_f{}'$ = $\frac{I_f}{l}$;
I_i = moment of inertia of the infilling, in m^4;
$I_u{}'$ = $\frac{I_U}{h_U}$;
$I_1{}'$ = $\frac{I_L}{h_i}$;
I_1 = moment of inertia of the lower column, in m^4;
I_f = moment of inertia of the foundation beam or raft in m^4;
I_u = moment of inertia of the upper column, in m^4; and
l = spacing of the columns, in m.

NOTE — The summation is to be done over all the storeys including the foundation beam or raft. In the case of the foundation, $I_f{}'$ replaces $I_b{}'$ and I_1 becomes zero, whereas for the topmost beam I_u becomes zero.

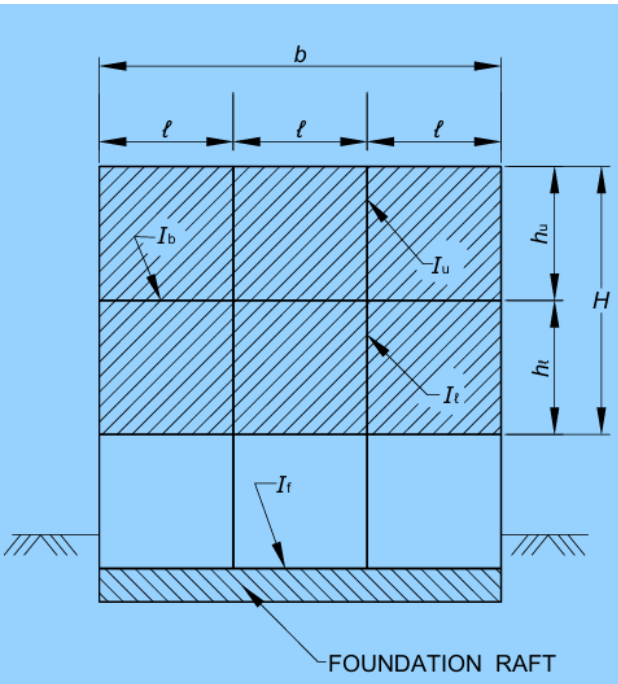

FIG. 12 DETERMINATION OF RIGIDITY OF STRUCTURE

C-2 RELATIVE STIFFNESS FACTOR, *K*

C-2.1 Whether a structure behaves as rigid or flexible depends on the relative stiffness of the structure and the foundation soil. This relation is expressed by the relative stiffness factor *K* given below:

a) For the whole structure, $K = \frac{EI}{E_s b^3 a}$;

b) For rectangular rafts, $K = \frac{E}{12E_s}\left(\frac{d}{b}\right)^3$; and

c) For circular rafts, $K = \frac{E}{12E_s}\left(\frac{d}{2R}\right)^3$

where

a = length perpendicular to the section under investigation, in m;

b = length of the section in the bending axis, in m;

d = thickness of the raft or beam, in m;

EI = flexural rigidity of the structure over the length (a), in kN/m^2;

E_s = modulus of compressibility of the foundation soil, in kN/m^2; and

R = radius of the raft, in m.

C-2.1.1 For $K > 0.5$, the foundation may be considered as rigid [*See* **7.4.4.1(a)**].

C-3 DETERMINATION OF CRITICAL COLUMN SPACING

Evaluation of the characteristics λ is made as follows:

$$\lambda = \sqrt[4]{\left(\frac{kB}{4E_c I}\right)}$$

where

B = width of raft B, in m;

E_c = modulus of elasticity of concrete in kN/m^2;

I = moment of inertia of raft, in m^4; and

k = modulus of subgrade reaction, in kN/m^3, for footing of width B, in m (*see* Annex B).

ANNEX D

(*Clause* 7.4.4.1.3)

CALCULATION OF PRESSURE DISTRIBUTION BY CONVENTIONAL METHOD

D-1 DETERMINATION OF PRESSURE DISTRIBUTION

The pressure distribution (q) under the raft shall be determined by the following formula:

$$q = \frac{Q}{A} \pm \frac{Qe_y{}'}{I_x{}'}y \pm \frac{Qe_x{}'}{I_y{}'}x$$

where

A = total area of the raft,

$\left.\begin{array}{l} e_x', \\ e_y' \\ I_x', \\ I_y' \end{array}\right\}$ = eccentricities and moments of inertia about the principal axes through the centroid of the section;

x, y = co-ordinates of any given point on the raft with respect to the *x* and *y* axes passing through the centroid of the area of the raft; and

Q = total vertical load on the raft.

I_x', I_y', e_x', e_y' may be calculated from the following equations:

$$I_x' = I_x - \frac{I_{\mathrm{xy}}^2}{I_y}$$

$$I_y' = I_y - \frac{I_{\mathrm{xy}}^2}{I_x}$$

$$e_x' = e_x - \frac{I_{\mathrm{xy}}}{I_x} e_y$$

$$e_y' = e_y - \frac{I_{\mathrm{xy}}}{I_y} e_x$$

where

$e_{\mathrm{x}}, e_{\mathrm{y}}$ = eccentricities in the x and y directions of the load from the centroid;

I_{xy} = $\int xy \cdot dA$ for the whole area about *x* and *y* axes through the centroid; and

$I_{\mathrm{x}}, I_{\mathrm{y}}$ = moment of inertia of the area of the raft respectively about the *x* and *y* axes through the centroid.

For a rectangular raft, the equation simplifies to :

$$q = \frac{Q}{A}\left(1 \pm \frac{12 e_y y}{b^2} \pm \frac{12 e_x x}{a^2}\right)$$

where

a and *b* = the dimensions of the raft in the x and y directions, respectively.

NOTE — If one or more of the values of (q) are negative as calculated by the above formula, it indicates that the whole area of foundation is not subject to pressure and only a part of the area is in contact with the soil and the above formula will still hold good, provided the appropriate values of I_{x}, I_{y}, I_{xy}, e_{x} and e_{y}, are used with respect to the area in contact with the soil instead of the whole area.

ANNEX E

[*Clause* 7.4.4.2(A)]

CONTACT PRESSURE DISTRIBUTION AND MOMENTS BELOW FLEXIBLE FOUNDATION

E-1 CONTACT PRESSURE DISTRIBUTION

E-1.1 The distribution of contact pressure is assumed to be linear with the maximum value attained under the columns and the minimum value at mid span.

E-1.2 The contact pressure for the full width of the strip under an interior column load located at a point *i* can be determined as [*see* Fig. 13(A)]:

$$p_i = \frac{5P_i}{\bar{l}} + \frac{48M_i}{(\bar{l})^2}$$

where

l = average length of adjacent span, in m;

M_i = moment under an interior columns loaded at I; and

P_i = column load, in t at point i.

E-1.3 The minimum contact pressure for the full width of the strip at the middle of the adjacent spans can be determined as [*see* Fig. 13(A) and Fig. 13(B)]:

$$p_{\mathrm{ml}} = 2P_i\left(\frac{l_r}{l_l\bar{l}}\right) - p_i\left(\frac{\bar{l}}{l_l}\right)$$

$$p_{\mathrm{mr}} = 2P_i\left(\frac{l_l}{l_r\bar{l}}\right) - p_i\left(\frac{\bar{l}}{l_r}\right)$$

$$p_m = \frac{p_{\mathrm{ml}} + p_{\mathrm{mr}}}{2}$$

where l_r, l_l are as shown in Fig. 13(A).

EXTERIOR PART

FIG.13(C) MOMENT AND PRESSURE DISTRIBUTION AT EXTERIOR COLUMNS

FIG. 13 MOMENT AND PRESSURE DISTRIBUTION AT COLUMNS

E-1.4 If E-2.3(a) governs the moment under the exterior columns, contact pressures under the exterior columns and at end of strip can be determined as [*see* Fig. 13(C)]:

$$p_e = \frac{4P_e + \frac{6M_e}{C} - p_m l_1}{C + l_1}$$

$$p_c = -\frac{3M_e}{C^2} - \frac{p_e}{2}$$

where P_e, p_m, M_e, l_1, C are as shown in Fig. 13(C).

E-1.5 If E-2.3(b) governs the moment under the exterior columns, the contact pressures are determined as [*see* Fig. 13(C)] :

$$p_e = p_c \frac{4P_e - p_m l_1}{4C + l_1}$$

E-2 BENDING MOMENT DIAGRAM

E-2.1 The bending moment under an interior column located at *i* [*see* Fig. 11(A)] can be determined as :

$$M_i = -\frac{P_i}{4\lambda}(0.24\lambda\bar{l} + 0.16)$$

E-2.2 The bending moment at mid span is obtained as [*see* Fig. 11(A)]:

$$M_m = M_o + M_i$$

M_i = average of negative moments M_i at each end of the bay

M_o = moment of simply supported beam

= $\frac{l^2}{48}[p_i(l) + 4\overline{p_m} + p_i(r)]$.

where l, $p_i(l)$, $p_i(r)$, $\overline{p_m}$ are as shown in Fig. 11(B).

E-2.3 The bending moment M_e under exterior columns can be determined as the least of [*see* Fig. 13(C)]:

a) $M_{e1} = -\frac{P_e}{4\lambda}(0.13\lambda l_1 + 1.06\lambda C - 0.50)$; and

b) $M_{e2} = -\frac{(4P_e - p_m l_1)}{(4C + l_1)}\frac{C^2}{2}$;

ANNEX F

[*Clause* 7.4.4.2(b)]

FLEXIBLE FOUNDATION — GENERAL CONDITION

F-1 CLOSED FORM SOLUTION OF ELASTIC PLATE THEORY

F-1.1 For a flexible raft foundation with non-uniform column spacing and load intensity, solution of the differential equation governing the behaviour of plates on elastic foundation (Winkler type) gives radial moment (M_r) tangential moment (M_t) and deflection (w) at any point by the following expressions:

$$M_r = -\frac{P}{4}\left[Z_4\left(\frac{r}{L}\right) - (1-\mu)\frac{Z_3'\left(\frac{r}{L}\right)}{\left(\frac{r}{L}\right)}\right]$$

$$M_t = -\frac{P}{4}\left[\mu Z_4\left(\frac{r}{L}\right) + (1-\mu)\frac{Z_3'\left(\frac{r}{L}\right)}{\left(\frac{r}{L}\right)}\right]$$

$$w = \frac{PL^2}{4D}\cdot Z_3\left(\frac{r}{l}\right)$$

where

L = radius of effective stiffness;

= $\left(\frac{D}{k}\right)^{1/4}$;

P column load; and

r distance of the point under investigation from column load along radius.

where

D = flexural rigidity of the foundation;

k = modulus of subgrade reaction for footing of width B;

P = $\frac{Et^2}{12(1-\mu)^2}$

E = modulus of elasticity of the foundation material;

T = raft thickness; and

μ = possion’s ratio of the foundation material.

$\left.\begin{array}{l} Z_3\left(\frac{r}{L}\right), \\ Z_3'\left(\frac{r}{L}\right), \\ Z_4\left(\frac{r}{L}\right) \end{array}\right\}$ = functions of shear, moment and deflection (*see* Fig. 14)

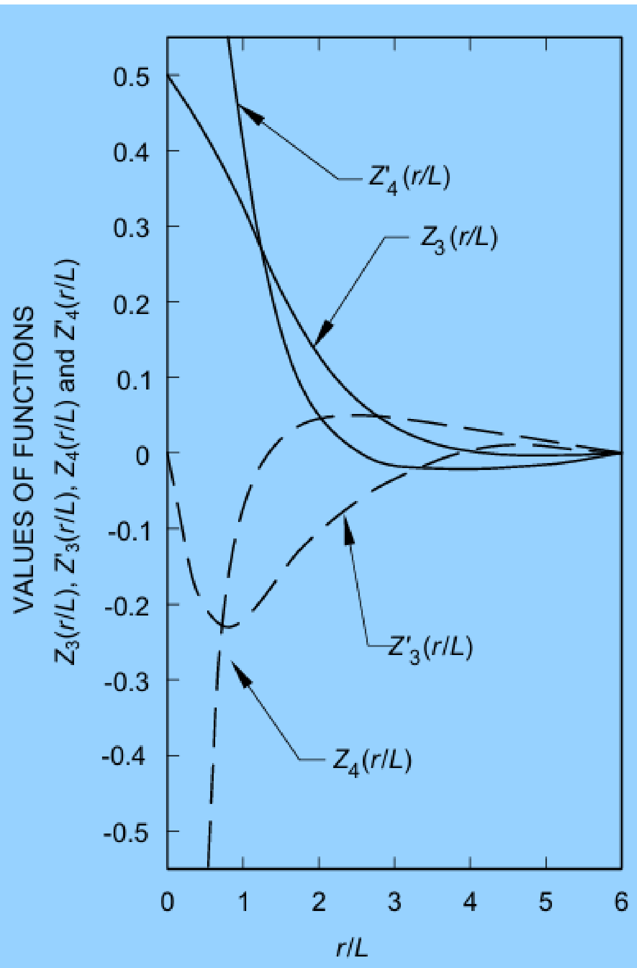

FIG.14 FUNCTIONS FOR SHEAR MOMENT AND DEFLECTION

F-1.2 The radial and tangential moments can be converted to rectangular co-ordinates:

$$M_x = M_r \cos^2 \varphi + M_t \sin^2 \varphi$$
$$M_y = M_r \sin^2 \varphi + M_t \cos^2 \varphi$$

where

Φ = angle with x-axis to the line jointing origin to the point under consideration.

F-1.3 The shear, Q per unit width of raft can be determined by :

$$Q = -\frac{P}{4L} Z_4' \left(\frac{r}{L}\right)$$

$Z_4' \left(\frac{r}{L}\right)$ = function for shear (*see* Fig. 14).

F-1.4 When the edge of the raft is located within the radius of influence, the following corrections are to be applied. Calculate moments and shears perpendicular to the edge of the raft within the radius of influence, assuming the raft to be infinitely large. Then apply opposite and equal moments and shears on the edge of the mat. The method for beams on elastic foundation may be used.

F-1.5 Finally, all moments and shears calculated for each individual column and wall are superimposed to obtain the total moment and shear values.

ANNEX G

(*Clauses* 8.2.3.3.1.1, 8.2.3.3.1.4 *and* 8.5.3.4)

LOAD CARRYING CAPACITY OF PILES — STATIC ANALYSIS

G-1 PILES IN GRANULAR SOILS

The ultimate load capacity (Q_u) of piles, in kN, in granular soils is given by the following formula:

$$Q_u = A_p(\tfrac{1}{2} D \gamma N_\gamma + P_D N_q) + \sum_{i=1}^{n} K_i \, P_{Di} \tan \delta_i A_{si} \qquad \ldots\ldots\ldots(1)$$

The first term gives end bearing resistance and the second term gives skin friction resistance.

where

A_{si} = surface area of pile shaft in the ith layer, in m^2;

A_p = cross-sectional area of pile tip, in m^2;

D = diameter of pile shaft, in m;

N_γ, N_q = bearing capacity factors depending upon the angle of internal friction, ϕ at pile tip;

K_i = coefficient of earth pressure applicable for the ith layer (*see* Note 3);

P_D = effective overburden pressure at pile tip, in kN/m^2 (*see* Note 5);

P_{Di} = effective overburden pressure for the ith layer, in kN/m^2;

$\sum_{i=1}^{n}$ = summation for layers 1 to n in which pile is installed and which contribute to positive skin friction;

δ_i = angle of wall friction between pile and soil for the ith layer; and

γ = effective unit weight of the soil at pile tip, in kN/m^3.

NOTES

1 N_γ factor can be taken for general shear failure according to good practice [C-2(34)].

2 N_q factor will depend on the nature of soil, type of pile, the L/B ratio and its method of construction. The values applicable for driven and bored piles are given in Fig. 15(A) and Fig. 15(B) respectively.

3 K_i, the earth pressure coefficient depends on the nature of soil strata, type of pile, spacing of piles and its method of construction. For bored piles in loose to dense sand with ϕ varying between 30°and 40°, K_i values in the range of 1 to 2 may be used for driven piles and in case of bored piles, K_i values in the range of 1 to 1.5 may be used.

4 δ, the angle of wall friction may be taken equal to the friction angle of the soil around the pile shaft.

5 In working out pile capacity by static formula, the maximum effective overburden at the pile tip should correspond to the critical depth, which may be taken as 15 times the diameter of the pile shaft for $\phi \leq 30°$ and increasing to 20 times for $\phi \geq 40°$.

6 For piles passing through cohesive strata and terminating in a granular stratum, a penetration of at least twice the diameter of the pile shaft should be given into the granular stratum.

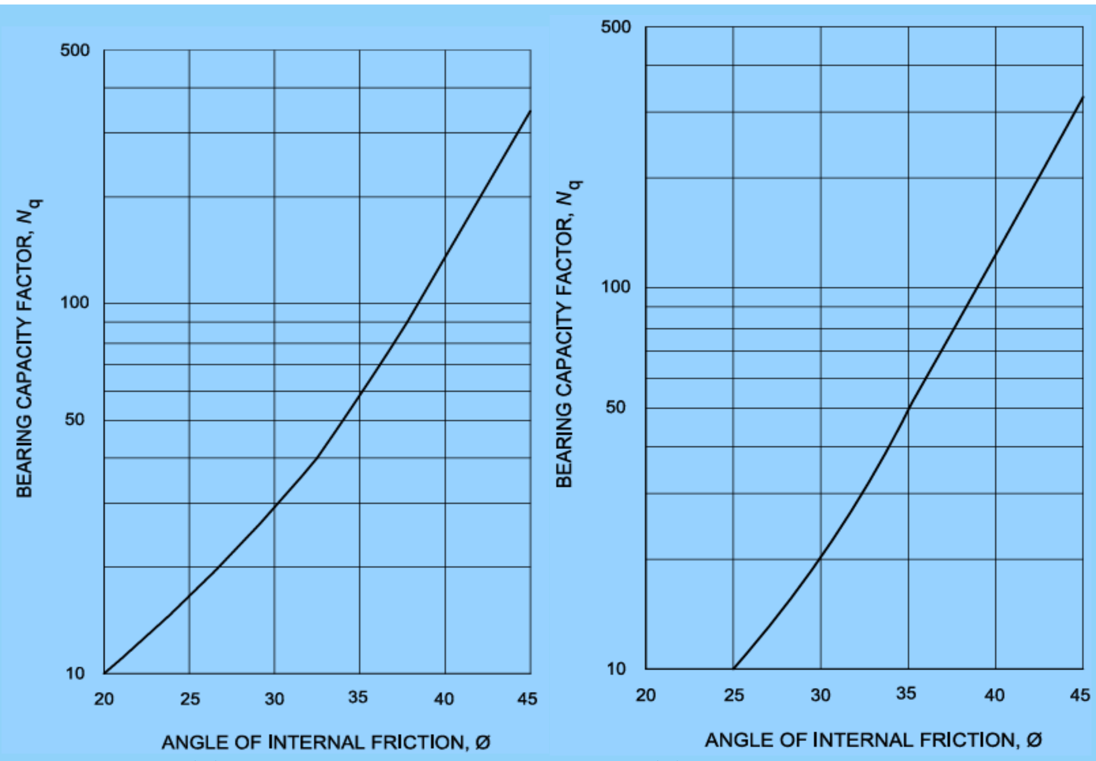

Fig.15(A) Bearing Capacity Factor, N_Q for Driven Piles

Fig.15(B) Bearing Capacity Factor, N_Q for Bored Piles

Fig. 15 Bearing Capacity Factor, N_Q

G-2 PILES IN COHESIVE SOILS

The ultimate load capacity (Q_u) of piles, in kN, in cohesive soils is given by the following formula:

$$Q_u = A_p N_c c_p + \sum_{i=1}^{n} \alpha ici Asi \qquad \text{..............(2)}$$

The first term gives end bearing resistance and the second term gives the skin friction resistance.

where

α_i = adhesion factor for the *i*th layer depending on the consistency of soil (*see* Note);

A_p = cross-sectional area of pile tip, in m^2;

A_{si} = surface area of pile shaft in the *i*th layer, in m^2;

c_i = average cohesion for the *i*th layer, in kN/m^2;

c_p = average cohesion at pile tip, in kN/m^2;

N_c = bearing capacity factor, may be taken as 9; and

$\sum_{i=1}^{n}$ = summation for layers 1 to *n* in which pile is installed and which contribute to positive skin friction.

NOTE — The value of adhesion factor, α_i depends on the undrained shear strength of the clay and may be obtained from Fig. 16.

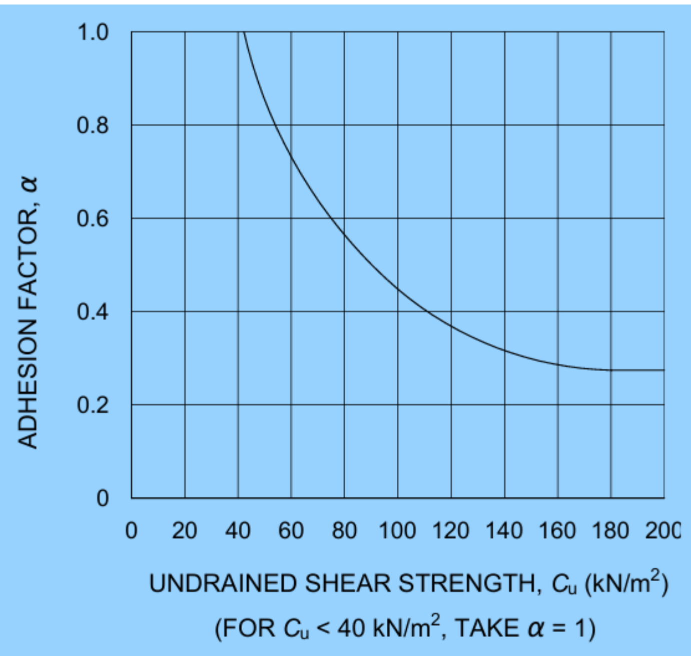

FIG. 16 VARIATION OF α WITH C_U

G-3 USE OF STATIC CONE PENETRATION DATA

G-3.1 When full static cone penetration data are available for the entire depth, the following correlation may be used as a guide for the determination of ultimate load capacity of a pile.

G-3.2 Ultimate end bearing resistance (q_u), in kN/m^2, may be obtained as:

$$q_u = \frac{\frac{q_{c0}+q_{c1}}{2} + q_{c2}}{2}$$

where

D = diameter of pile shaf;.

q_{c0} = average static cone resistance over a depth of 2D below the pile tip, in kN/m^2;

q_{c1} = minimum static cone resistance over the same 2D below the pile tip, in kN/m^2; and

q_{c2} = average of the envelope of minimum static cone resistance values over the length of pile of 8D above the pile tip, in kN/m^2.

G-3.3 Ultimate skin friction resistance can be approximated to local side friction (f_s), in kN/m^2, obtained from static cone resistance as given in Table 10.

Table 10 Side Friction for Different Soil Types

(*Clause* G-3.3)

Sl No. (1)	Type of Soil (2)	Local Side Friction, f_s kN/m^2 (3)
i)	q_c less than 1 000 kN/m^2	$q_c/30 < f_s < q_c/10$
ii)	Clay	$q_c/25 < f_s < 2q_c/25$
iii)	Silty clay and silty sand	$q_c/100 < f_s < q_c/25$
iv)	Sand	$q_c/100 < f_s < q_c/50$
v)	Coarse sand and gravel	$q_c/100 < f_s < q_c/150$

where q_c = cone resistance, in kN/m^2.

G-3.4 The correlation between standard penetration resistance, N (blows/30 cm) and static cone resistance, q_c, in kN/m^2, as given in Table 11 may be used for working out the end bearing resistance and skin friction resistance of piles. This correlation should only be taken as a guide and should preferably be established for a given site as they can vary substantially with the grain size, Atter berg limits, water table, etc.

Table 11 Co-Relation between N and q_c for Different Types of Soil

(*Clause* G-3.4)

Sl No. (1)	Type of Soil (2)	q_c/N (3)
i)	Clay	150 to 200
ii)	Silts, sandy silts and slightly cohesive silt-sand mixtures	200 to 250
iii)	Clean fine to medium sand and slightly silty sand	300 to 400
iv)	Coarse sand and sands with little gravel	500 to 600
v)	Sandy gravel and gravel	800 to 1 000

G-4 USE OF STANDARD PENETRATION TEST DATA FOR COHESIONLESS SOIL

G-4.1 The correlation suggested by Meyerhof using standard penetration resistance, N in saturated cohesionless soil to estimate the ultimate load capacity of driven pile is given below. The ultimate load capacity of pile (Q_u), in kN, is given as:

$$Q_u = 40\,N\frac{L_b}{D}A_p + \frac{\overline{N}A_s}{0.50} \quad \ldots\ldots\ldots\ldots(3)$$

The first term gives the end bearing resistance and the second term gives the frictional resistance.

where

A_s = surface area of pile shaft, in m^2;

A_p = cross-sectional area of pile tip, in m^2;

D = diameter or minimum width of pile shaft, in m;

L_b = length of penetration of pile in the bearing strata, in m;

$\overline{N}$ = average N along the pile shaft; and

N = average N values at pile tip;

NOTE — The end bearing resistance should not exceed 400 NA_p

G-4.2 For non-plastic silt or very fine sand the equation has been modified as:

$$Q_u = 30\, N \frac{L_b}{D} A_p + \frac{\overline{N} A_s}{0.60} \qquad (4)$$

The meaning of all terms is same as for equation 3.

G-4.3 The correlation suggested by Meyerhof using standard penetration resistance, N in saturated cohesionless soil to estimate the ultimate load capacity of bored pile is given below. The ultimate capacity of pile (Q_u), in kN, is given as:

$$Q_u = 13\, N \frac{L_b}{D} A_p + \frac{\overline{N} A_s}{0.50} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots..(5)$$

The first term gives end bearing resistance and the second term gives frictional resistance.

The meaning of all terms is same as for equation 3.

NOTE —The end bearing resistance should not exceed 130 NA_p.

G-4.4 For non-plastic silt or very fine sand the equation has been modified as:

$$Q_u = 10\, N \frac{L_b}{D} A_p + \frac{\overline{N} A_s}{0.60} \ldots\ldots\ldots\ldots\ldots\ldots\ldots..(6)$$

The meaning of all terms is same as for equation 3.

G-5 FACTOR OF SAFETY

The minimum factor of safety for arriving at the safe pile capacity from the ultimate capacity obtained by using static formulae shall be 2.5.

G-6 PILES IN STRATIFIED SOIL

In stratified soil/C-ϕ soil, the ultimate load capacity of piles should be determined by calculating the skin friction and end bearing in different strata by using appropriate expressions given in G-1 and G-2.

G-7 PILES IN HARD ROCK

When the crushing strength of the rock is more than characteristic strength of pile concrete, the rock should be deemed as hard rock. Bored piles resting directly on hard rock may be loaded to their safe structural capacity.

G-8 PILES IN WEATHERED / SOFT ROCK

For bored piles founded in weathered/soft rock different empirical approaches are used to arrive at the socket length necessary for utilizing the full structural capacity of the pile.

Since it is difficult to collect cores in weathered/soft rocks, the method suggested by Cole and Stroud using 'N' values is more widely used. The allowable load on the pile, Q_a, in kN, by this approach, is given by:

$$Q_a = c_{u1} N_c \cdot \frac{\pi B^2}{4 F_s} + \alpha\, c_{u2} \cdot \frac{\pi B L}{F_s}$$

where

α = 0.9 (recommended value);

B = minimum width of pile shaft (diameter in case of circular piles),in m;

c_{u1} = shear strength of rock below the base of the pile, in kN/m^2 (*see* Fig. 17);

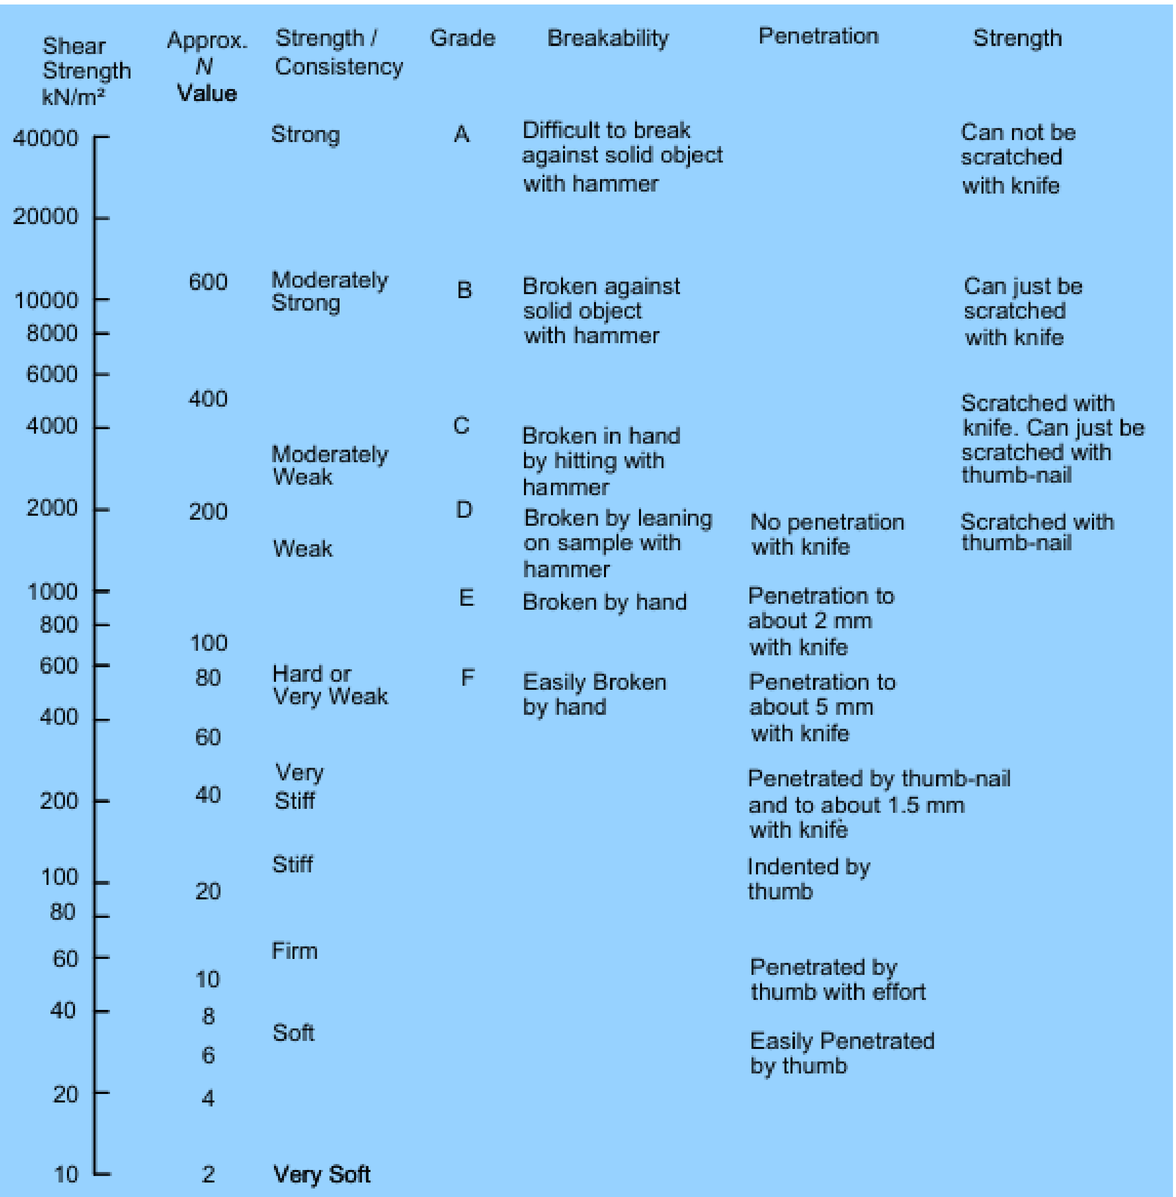
c_{u2} = average shear strength of rock in the socketed length of pile, in kN/m^2 (*see* Fig. 17);

F_s = factor of safety usually taken as 3;

L = socket length of pile, in m; and

N_c = bearing capacity factor taken as 9.

NOTE — For $N \geq 60$, the stratum is to be treated as weathered rock rather than soil.



NOTE – Standard penetration test may not be practicable for *N* values greater than 200. In such cases, design may be done on the basis of shear strength of rock.

FIG. 17 CONSISTENCY AND SHEAR STRENGTH OF WEATHERED ROCK

ANNEX H

(*Clause* 8.2.3.5.2)

ANALYSIS OF LATERALLY LOADED PILES

H-1 GENERAL

H-1.1 The ultimate resistance of a vertical pile to a lateral load and the deflection of the pile as the load builds up to its ultimate value are complex matters involving the interaction between a semi-rigid structural element and soil which deforms partly elastically and partly plastically. The failure mechanisms of an infinitely long pile and that of a short rigid pile are different. The failure mechanisms also differ for a restrained and unrestrained pile head condition.

Because of the complexity of the problem only a procedure for an approximate solution that is adequate in most of the cases is presented here. Situations that need a rigorous analysis shall be dealt with accordingly.

H-1.2 The first step is to determine, if the pile will behave as a short rigid unit or as an infinitely long flexible member. This is done by calculating the stiffness factor R or T for the particular combination of pile and soil.

Having calculated the stiffness factor, the criteria for behaviour as a short rigid pile or as a long elastic pile are related to the embedded length L_e of the pile. The depth from the ground surface to the point of virtual fixity is then calculated and used in the conventional elastic analysis for estimating the lateral deflection and bending moment.

H-2 STIFFNESS FACTORS

H-2.1 The lateral soil resistance for granular soils and normally consolidated clays which have varying soil modulus is modelled according to the equation:

$$\frac{p}{y} = \eta_h z$$

where

η_h = modulus of subgrade reaction for which the recommended values are given in Table 12;

p = lateral soil reaction per unit length of pile at depth z below ground level; and

y = lateral pile deflection.

H-2.2 The lateral soil resistance for over-consolidated clays with constant soil modulus is modelled according to the equation:

$$\frac{p}{y} = K$$

where

$$K = \frac{k_1}{1.5} \times \frac{0.3}{B}$$

where k_1 is Terzaghi's modulus of subgrade reaction as determined from load deflection measurements on a 30 cm square plate and B is the width of the pile (diameter in case of circular piles). The recommended values of k_1 are given in Table 13.

Table 12 Modulus of Subgrade Reaction for Granular Soils and Normally Consolidated Clays, η_h, kN/m^3

(*Clause* H-2.1 *and* H-2.3.1)

Sl No.	**Soil Type**	***N* (Blows/30 cm)**	**Range of η_h** kN/m^3 × 10^3	
			Dry	Submerged
(1)	(2)	(3)	(4)	(5)
i)	Soft organic silt	—	—	0.15
ii)	Soft normally consolidated clay	0 to 4	—	0.35 to 0.7
iii)	Very loose sand	0 to 4	< 0.4	< 0.2
iv)	Loose sand	4 to 10	0.4 to 2.5	0.2 to 1.4
v)	Medium sand	10 to 35	2.5 to 7.5	1.4 to 5.0
vi)	Dense sand	> 35	7.5 to 20.0	5.0 to 12.0

NOTE — The η_h values may be interpolated for intermediate standard penetration values, *N*.

Table 13 Modulus of Subgrade Reaction for Cohesive Soil, k_1, KN/m^3

(*Clauses* H-2.2 *and* H-2.3.2)

Sl No.	**Soil consistency**	**Unconfined compression strength, q_u** kN/m^2	**Range of k_1** kN/m^3 × 10^3
(1)	(2)	(3)	(4)
i)	Soft	25 to 50	4.5 to 9.0
ii)	Medium stiff	50 to 100	9.0 to 18.0
iii)	Stiff	100 to 200	18.0 to 36.0
iv)	Very stiff	200 to 400	36.0 to 72.0
v)	Hard	> 400	>72.0

NOTE — For q_u less than 25, k_1 may be taken as zero, which implies that there is no lateral resistance.

H-2.3 Stiffness Factors

H-2.3.1 *For Piles in Sand and Normally Consolidated Clays*

$$\text{Stiffness factor } T\text{, in m} = \sqrt[5]{\frac{EI}{\eta_h}}$$

where

E = young’s modulus of pile material, in MN/m^2;

I = moment of inertia of the pile cross-section, in m^4; and

η_h = modulus of subgrade reaction variation, in MN/m^3 (*see* Table 12).

H-2.3.2 *For Piles in Over-Consolidated Clays*

$$\text{Stiffness factor } R\text{, in m} = \sqrt[4]{\frac{EI}{KB}}$$

where

B = width of pile shaft (diameter in case of circular piles), in m;

E = young's modulus of pile material, in MN/m^2;

I = moment of inertia of the pile cross-section, in m^4; and

K = $\frac{k_1}{1.5} \times \frac{0.3}{B}$, (*See* Table 13 for values of k_1, in MN/m^3, *See also* Note).

NOTE — Table 13 shall be referred if the average unconfined compression strength, q_u is greater than or equal to 100 kN/m^2.

H-3 CRITERIA FOR SHORT RIGID PILES AND LONG ELASTIC PILES

Having calculated the stiffness factor T or R, the criteria for behaviour as a short rigid pile or as a long elastic pile are related to the embedded length L_e as given in Table 14.

Table 14 Criteria for Behaviour of Pile Based on its Embedded Length

(*Clause* H-3)

Sl No.	**Type of Pile Behaviour**	**Relation of Embedded Length with Stiffness Factor**	
		Linearly Increasing	Constant
(1)	(2)	(3)	(4)
i)	Short (rigid) pile	$L_e \leq 2T$	$L_e \leq 2R$
ii)	Long (elastic) pile	$L_e \geq 4T$	$L_e \geq 3.5R$

NOTE — The intermediate L shall indicate a case between rigid pile behaviour and elastic pile behaviour.

H-4 DEFLECTION AND MOMENTS IN LONG ELASTIC PILES

H-4.1 Equivalent cantilever approach gives a simple procedure for obtaining the deflections and moments due to relatively small lateral loads. This requires the determination of depth of virtual fixity, z_f.

The depth to the point of fixity may be read from the plots given in Fig. 18. e is the effective eccentricity of the point of load application obtained either by converting the moment to an equivalent horizontal load or by actual position of the horizontal load application. R and T are the stiffness factors described earlier.

H-4.2 The pile head deflection, y shall be computed using the following equations:

Deflection, $y = \frac{H(e+z_f)^3}{3EI} \times 10^3$ …….for free head pile

Deflection, $y = \frac{H(e+z_f)^3}{12EI} \times 10^3$ …….for fixed head pile

where

e	cantilever length above ground/bed to the point of load application, in m;
E	young's modulus of pile material, in kN/m^2;
H	lateral load, in kN;
I	moment of inertia of the pile cross section, in m^4;
y	deflection of pile head, in mm; and
z_f	depth to point of fixity, in m.

H-4.3 The fixed end moment of the pile for the equivalent cantilever may be determined from the following expressions.

Fixed end moment, $M_F = H(e + z_f)$ ……….for free head pile

Fixed end moment, $M_F = \frac{H(e+z_f)}{2}$ ……….for fixed head pile

The fixed head moment, M_F of the equivalent cantilever is higher than the actual maximum moment M in the pile. The actual maximum moment may be obtained by multiplying the fixed end moment of the equivalent cantilever by a reduction factor, m, given in Fig. 19.

FIG. 19 DETERMINATION OF REDUCTION FACTORS FOR COMPUTATION OF MAXIMUM MOMENT IN PILE

ANNEX J

(*Clause* 8.5.3.2)

LOAD CARRYING CAPACITY OF UNDER-REAMED PILES FROM SOIL PROPERTIES

J-1 ULTIMATE LOAD CAPACITY

The ultimate load capacity of a pile can be calculated from soil properties. The soil properties required are strength parameters, cohesion, angle of internal friction and soil density.

a) *Clayey soils* — For cohesive soils, the ultimate load carrying capacity of an under-reamed pile may be worked out from the following expression:

$$Q_u = A_p N_c C_p + A_a N_c C'_a + C'_a A'_s + \alpha C_a A_s$$

where

A_a = $(\pi/4)(D_u^2 - D^2)$, where D_u and D are the under-reamed and stem diameter, respectively, in m;

A_p = cross-sectional area of the pile stem at the pile tip, in m^2;

A_s = surface area of the stem, in m^2;

A'_s = surface area of the cylinder circumscribing the under-reamed bulbs, in m^2;

α = reduction factor (usually taken 0.5 for clays);

C_a = average cohesion of the soil along the pile stem, in kN/m^2;

C'_a = average cohesion of the soil around the under-reamed bulbs;

C_p = cohesion of the soil around toe, in kN/m^2;

N_c = bearing capacity factor, usually taken as 9; and

Q_u = ultimate bearing capacity of pile, in kN.

NOTES

1 The above expression holds for the usual spacing of under-reamed bulbs spaced at not more than one and a half times their diameter.

2 If the pile is with one bulb only, the third term will not occur. For calculating uplift load, the first term will not occur in the formula.

3 In case of expansive soil, top 2 m strata should be neglected for computing skin friction.

b) *Sandy soils*

$$Q_u = A_p\,(\frac{1}{2}D.\gamma.N_\gamma + \gamma.d_f.N_q) + A_a\,[\frac{1}{2}D_u.n.\gamma.N_\gamma + \gamma.N_q.(\sum_{r=1}^{r=n} d_r)] + \frac{1}{2}.\pi.D.\gamma.K\tan\delta\,.(d_1{}^2 + d_f{}^2 - d_n{}^2)$$

where

A_a = $\pi/4\ (D_u^2 - D^2)$ where D_u is the under-reamed bulb diameter, in m;

A_p = $\pi\ D^2/4$, where D is stem diameter, in m;

d_1 = depth of the centre of the first under-reamed bulb, in m;

d_f = total depth of pile below ground level, in m;

d_n = depth of the centre of the last under-reamed bulb, in m;

d_r = depth of the centre of different under-reamed bulbs below ground level, in m;

K = earth pressure coefficient (usually taken as 1.75 for sandy soils);

n = number of under-reamed bulbs;

N_Y, N_q = bearing capacity factors, depending upon the angle of internal friction;

γ = average unit weight of soil (submerged unit weight in strata below water table), in kN/m^3; and

δ = angle of wall friction (may be taken as equal to the angle of internal friction $\emptyset$)

NOTES

1 For uplift bearing on pile tip, A_p will not occur.

2 N_Y will be as specified in good practice [C-2(34)] and N_q will be taken from Fig. 15(B).

c) *Soil strata having both cohesion and friction* — In soil strata having both cohesion and friction or in layered strata having two types of soil, the bearing capacity may be estimated using both the formulae. However, in such cases load test will be a better guide.

d) *Compaction piles in sandy strata* — For bored compaction piles in sandy strata, the formula in (b) shall be applied but with the modified value of $\emptyset_1$ as given below:

$$\Phi_1 = (\Phi + 40)/2$$

where

$$\Phi = \text{angle of internal friction of virgin soil.}$$

The values of N_Y, N_q and δ are taken corresponding to Φ_1. The value of the earth pressure coefficient K will be 3.

e) *Piles resting on rock* — For piles resting on rock, the bearing component will be obtained by multiplying the safe bearing capacity of rock with bearing area of the pile stem plus the bearing provided by the bulb portion.

NOTE — To obtain safe load in compression and uplift from ultimate load capacity generally the factors of safety will be 2.5 and 3, respectively.

ANNEX K

(*Clause* 9.3.3.4)

LOAD CARRYING CAPACITY

K-1 LOAD CARRYING CAPACITY OF CPRF SYSTEM

K-1.1 The ultimate vertical capacity shall be taken as the least of:

a) the capacity of the block containing the piles, plus that of the portion of the raft outside the periphery of the pile group;

b) the sum of the capacity of the raft, $Q_{\text{unpiled-raft}}$ and of all the piles $Q_{\text{pile-group}}$ in the system, expressed as, $Q_{\text{CPRF}} = 0.8\,(Q_{\text{unpiled-raft}} + Q_{\text{pile-group}})$; and

c) the capacity of CPRF system considering pile-soil-raft interactions. The capacity of CPRF should be expressed as:

$$\mathrm{Q}_{\mathrm{CPRF}} = \alpha_{pr}\alpha_{pp}\sum_{n=1}^{n} Q_{single\ pile} + \alpha_{rp}Q_{unpiled\ raft}$$

In the above expression:

1) $Q_{unpiled\ raft}$ should be calculated based on good practice [C-2(34)];

2) $Q_{single\ pile}$ should be calculated based on good practice [C-2(51)]; and

3) α_{pp}, α_{rp} and α_{pr} are the pile-pile, raft-pile and pile-raft interaction factors, respectively. These interaction factors may be suitably taken from various relevant literature.

ANNEX L

(*Clause* 11.2)

SOIL IMPROVEMENT METHODS

L-1 SUMMARY OF SOIL IMPROVEMENT METHODS

	Method	Principle	Most Suitable Soil Conditions/ Types	Maximum Effective Treatment Depth	Special Materials Required	Special Equipment Required	Properties of Treated Material	Special Advantages and Limitation	Relative Cost
In-Situ Deep compaction of Cohesionless Soils	Blasting	Shock waves and vibrations cause liquefaction; displacement with settlement to higher density	Saturated, clean sands: partly saturated sands and silts (collapsible loss) after flooding	> 30 m	Explosives, backfill to plug drill holes, hole casings	Jetting or drilling machine	Can obtain relative densities to 70 to 80, may get variable density strength gain	Rapid, inexpensive, can treat any size areas: variable properties, no improvement near surface, dangerous	Low
	Vibratory Probe	Densification by vibration; liquefaction induced settlement under overburden	Saturated or dry clean sand	20 m (Ineffective above 3 m to 4 m depth)	None	Vibratory pile driver and 750 mm dia open steel pipe	Can obtain relative densities of up to 80 percent. Ineffective in some sands	Rapid, simple, good underwater, soft under layers may damp vibrations, difficult to penetrate, stiff over layers, not good in partly saturated soils	Moderate
	Vibro-compaction	Densification by vibration and compaction of backfill material	Cohesionless soils with less than 20 fines	30 m	Granular backfill, water supply	Vibroflot, crane, pumps	Can obtain high relative densities, good uniformity	Useful in saturated and partly saturated soils, uniformity	Moderate
In-Situ Deep compaction of Cohesionless Soils	Compaction piles	Densification by displacement of pile volume and by vibration during driving	Loose sandy soils: partly saturated clayey soils, loess	> 20 m	Pile material (often sand or soil plus cement mixture)	Pile driver, special sand pile equipment	Can obtain high densities, good uniformity	Useful in soils with fines, uniform compaction, easy to check results, slow, limited improvement in upper 1 m to 2 m	Moderate to high

Table (*Continue*)

	Method	Principle	Most Suitable Soil Conditions/ Types	Maximum Effective Treatment Depth	Special Materials Required	Special Equipment Required	Properties of Treated Material	Special Advantages and Limitation	Relative Cost
	Displacements grout	Highly viscous grout acts as radical hydraulic jack when pumped in under high pressure	Soft, fine-grained soils; foundation soils with large voids or cavities	Unlimited, but a few metre usual	Soil, cement water	Batching equipment, high pressure pumps, hoses	Grout bulbs within compressed soil matrix	Good for correction of differential settlements, filling large voids; careful control required	Low material high injection
	Electro-kinetic injection	Stabilization chemicals moved into soil by electro-osmosis or colloids into pores by electrophoresis	Saturated silts; silty clays (clean sands in case of colloid injection)	Unknown	Chemicals stabilizer colloidal void fillers	d.c. power supply, anodes, cathodes	Increased strength, reduced compressibility reduced liquefaction potential	Existing soil and structures not subjected to high pressures; not good in soils with high conductivity	Expansive
	Jet grouting	High speed jets at depth excavate, inject and mix stabilizer with soil to form columns or panels	Sands, silts, clays	—	Water, stabilizing chemicals	Special jet nozzle, pumps, pipes and hoses	Solidified columns and walls	Useful in soils that can't be permeation grouted, precision in locating treated zones	--

Table (*Continue*)

	Method	Principle	Most Suitable Soil Conditions/ Types	Maximum Effective Treatment Depth	Special Materials Required	Special Equipment Required	Properties of Treated Material	Special Advantages and Limitation	Relative Cost
Precompression	Preloading with/without drain	Load is applied sufficiently in advance of construction so that compression of soft soils is completed prior to development of the site	Normally consolidated soft clays, silts, organic deposits, completed sanitary landfills	—	Earth fill or other material for loading the site; sand or gravel for drainage blanket	Earth moving equipment, large water tanks or vacuum drainage systems sometimes used; settlement markers, piezometers	Reduced water content and void ratio, increased strength	Easy, theory well developed, uniformity; requires long time (vertical drains can be used to reduce consolidation time)	Low (moderate, if vertical drains are required)
	Surcharge fills	Fill in excess of that required permanently is applied to achieve a given amount of settlement in a shorter time; excess fill then removed	Normally consolidated soft clays, silts, organic deposits, completed sanitary landfills	—	Earth fill or other material for loading the site; sand or gravel for drainage blanket	Earth moving equipment; settlement markers, piezometers	Reduced water content, void ratio and compressibility increased strength	Faster than preloading without surcharge, theory well developed, extra material handling; can use vertical drains to reduce consolidation time	Moderate
	Electro-osmosis	d. c. current causes water flow from anode towards cathode where it is removed	Normally consolidated silts and silty clays	—	Anodes (usually rebars or aluminium) cathodes (well points or rebars)	d. c. power supply, wiring, metering systems	Reduced water content and compressibility, increased strength, electrochemical hardening	No fill loading required, can be used in confined area, relatively fast; non-uniform properties between electrodes; not good in highly conductive soils	High

Table (*Continue*)

	Method	**Principle**	**Most Suitable Soil Conditions/ Types**	**Maximum Effective Treatment Depth**	**Special Materials Required**	**Special Equipment Required**	**Properties of Treated Material**	**Special Advantages and Limitation**	**Relative Cost**
Admixtures	Remove and replace	Foundation soil excavated, improved by drying or admixture and re-compacted	Inorganic soils	10 m	Admixture stabilizers	Excavating, mixing and compaction equipment, dewatering system	Increased strength and stiffness, reduced compressibility	Uniform, controlled foundation soil when replaced; may require large area dewatering	High
	Structural fills	Structural fill distributes loads to underlying soft soils	Use over soft clays or organic soils, marsh deposits	—	Sand, gravel fly ash, bottom ash, slag, expanded aggregate, clam shell or oyster shell, incinerator ash	Mixing and compaction equipment	Soft subgrade protected by structural load-bearing fill	High strength, good load distribution to underlying soft soils	Low to high
	Mix-in-place piles and walls	Lime cement or asphalt introduced through rotating auger or special in-place mixer	All soft or loose inorganic soils	>20 m	Cement lime asphalt, or chemical stabilizer	Drill rig, rotary cutting and mixing head, additive pro-portioning equipment	Solidified soil piles for walls of relatively high strength	Use native soil, reduced lateral support requirements during excavation; difficult quality control	Moderate to high

Table (Continue)

	Method	Principle	Most Suitable Soil Conditions/ Types	Maximum Effective Treatment Depth	Special Materials Required	Special Equipment Required	Properties of Treated Material	Special Advantages and Limitation	Relative Cost
Thermal	Heating	Drying at low temperatures; alteration of clays at intermediate temperatures (400 to 600 °C); fusion at high temperatures (>1 000 °C)	Fine-grained soils, especially partly saturated clays and silts, loess	15 m	Fuel	Fuel tanks, burners, blowers	Reduced water content, plasticity, water sensitivity; increased strength	Can obtain irreversible improvements in properties; can introduce stabilizers with hot gases	High
	Freezing	Freeze soft, wet ground to increase its strength stiffness	All soils	Several metre	Refrigerant	Refrigeration system	Increased strength and stiffness, reduced permeability	No good in flowing ground water, temporary	High
Reinforcement	Vibro replacement sand/stone columns	Hole jetted into soft, fine-grained soil and backfilled with densely compacted gravel or sand	Soft clays and alluvial deposits	20 m	Gravel or crushed rock backfill	Vibroflot, crane or vibrocat, water	Increased bearing capacity, reduced settlement	Faster than precompression, avoids dewatering required for remove and replace; limited bearing capacity	Moderate to high
	Root piles, soils nailing	Inclusions used to carry tension, shear, compression	All soils	—	Reinforcing bars, cement grout	Drilling and grouting equipment	Reinforced zone behaves as a coherent mass	*In-situ* reinforcement for soils that can't be grouted or mixed in-place with admixtures	Moderate to high

Table (*Concluded*)

	Method	Principle	Most Suitable Soil Conditions/ Types	Maximum Effective Treatment Depth	Special Materials Required	Special Equipment Required	Properties of Treated Material	Special Advantages and Limitation	Relative Cost
	Strips and membranes	Horizontal tensile strips, membranes buried in soil under embankments, gravel base courses and footings	All soils	Can construct earth structures to heights of several metres	Metal or plastic strips, geotextiles	Excavating, earth handling and compaction equipment	Self-supporting earth structures, increased bearing capacity, reduced deformations	Economical, earth structures coherent, can tolerate deformations; increased allowable bearing pressure	Low to moderate

LIST OF STANDARDS

The following list records those standards which are acceptable as ‘good practice’ and ‘accepted standards’ in the fulfilment of the requirements of this NBCS. The latest version of a standard shall be adopted at the time of enforcement of this NBCS. The standards listed may be used for conformance with the requirements of the referred clauses in this NBCS.

In the following list, the number appearing in the first column within parentheses indicates the number of the reference in this Part/Section of this NBCS.

	IS No.	*Title*
(1)	IS 1892 : 2021	Subsurface investigation for foundations — Code of practice (*second revision*)
	IS 2131 : 2025	Standard penetration test of soil — Method of test (*second revision*)
	IS 2132 : 1986	Code of practice for thin walled tube sampling of soils (*second revision*)
	IS 4434 : 1978	Code of practice for *in-situ* vane shear test for soils (*first revision*)
	IS 4968	Method for subsurface sounding for soils
	(Part 1) : 1976	Dynamic method using 50 mm cone without bentonite slurry (*first revision*)
	(Part 2) : 1976	Dynamic method using cone and bentonite slurry (*first revision*)

FOREWORD

This NBCS (Part C/Subsection 3A) deals with the structural design aspect of timber structures. In this Subsection, the various species of Indian timber, classified into three groups depending on the structural properties influencing the design most, are included.

This Section was first published in 1970 which was subsequently revised in 1983, 2005 and 2016 as a part of National Building Code of India. In the 1983 version of this code, timber was covered under Section 3 of Part 6 under the title ‘Wood’, which did not cover bamboo. In the version of 2005, the scope of Section 3 was enlarged as Section 3 Timber and Bamboo, which was subdivided into Subsection 3A ‘Timber’ and Subsection 3B ‘Bamboo’. This Subsection pertains to 3A ‘Timber’.

In the first revision of 1983, provisions of this Subsection were updated and design of nailed laminated timber beams, were included and information on bolted construction joints was added. In the second revision of 2005, a number of terminologies related to timber for structural purpose were added, strength data of additional species of timber were included, requirements for structural timber and preferred cut sizes thereof were modified, requirements for glued laminated construction and finger joints and also for laminated veneer lumber were introduced. Brief details were included for structural sandwiches, glued laminated beams, lamella roofing, nail and screw holding power of timber, structural use of plywood and trussed rafter. Further, guidelines for protection against termite attack in buildings were also incorporated in the last revision of this Subsection. Also, keeping into consideration the dwindling forest resources, brief details on use of plantation timbers including certain fast growing species and suitable guidelines in terms of their seasoning, sawing, treatment, etc and also use of finger jointing and glued laminated timber was introduced in the last revision so as to effect judicious use of timber.

The third revision of 2016 addressed several significant changes, including modifications to definitions of various terms to align with prevailing engineering practices and the addition of new terminologies related to structural timber. The permissible lateral strength (in double shear) of mild steel common wire was updated to include various new timber species, with modified strength values for certain existing species based on the latest research. Guidance on increased permissible lateral strength for mild steel nails clenched across the grain, as opposed to nails with points cut flush, was incorporated. Design provisions for timber connector joints were further updated, along with data on block shear test results of glued timber joints based on indigenous studies. Additionally, information on the strength properties of glued finger joints from indigenous research was included for design guidance. A new figure illustrating possible orientations of planks in glue-laminated beams (glulam) was added, as well as a design outline for horizontally laminated beams. Updates were also made to the design provisions for trussed rafters, including data on lateral load-bearing strength of common wire nails in plywood-to-wood joints. Provisions for lamella roofing design were detailed and the composite nail/screw-holding power of specific Indian timbers was provided for design guidance.

In this revision, this publication has been renamed as National Building Construction Standards (NBCS).

As a result of experience gained in implementation of 2016 version and feedback received as well as formulation of new standards in the field and revision/updation of some of the existing standards, a need to revise this Subsection was felt. This revision has, therefore, been brought out to take care of these aspects.

The significant changes incorporated in this revision include the following:

a) Cross-laminated timber components including material specifications, dimensions, and fire resistance requirements;

b) Mass timber construction and its components given in 21;

c) Fire safety enhancements and fire-resistant assembly methods for mass timber, ensuring compliance with structural and fire safety standards;

d) Focus on sustainability with introduction of life cycle assessment (LCA) to evaluate the environmental impact of timber from production to disposal; and

e) Introduction of mechanical properties of foreign timber species, to support informed design, specification and safe application.

Reference may be made to Part F ‘Fire and Life Safety’ of this NBCS for fire protection of the timber buildings.

The information contained in this Subsection is largely based on the following Indian Standards:

IS 399 : 1963	Classification of commercial timbers and their zonal distribution (*revised*)
IS 883 : 2016	Design of structural timber in building — Code of practice for (*fifth revision*)
IS 1150 : 2000	Trade names and abbreviated symbols for timber species (*third revision*)
IS 2366 : 1983	Code of practice for nail-jointed timber construction (*first revision*)
IS 4891 : 1988	Specification for preferred cut sizes of structural timber (*first revision*)
IS 4983 : 1968	Code of practice for design and construction of nailed laminated timber beams
IS 11096 : 1984	Code of practice for design and construction of bolt jointed timber construction
IS 14616 : 1999	Laminated veneer lumber — Specification

As the regulation of land development and buildings is a State subject and is dealt by the States and local bodies such as urban local bodies within their jurisdiction through building regulatory documents like building regulations, building byelaws and fire regulations, this document is voluntary in nature and is non-binding. The implementation depends on adoption by concerned parties or stipulations in a contract or by appropriate adoption by the concerned authorities.

For the purpose of deciding whether a particular requirement of this Subsection is complied with, the final value, observed or calculated, expressing the result of a test or analysis, shall be rounded off in accordance with IS 2 : 2022 ‘Rules for rounding off numerical values (*second revision*)’. The number of significant places retained in the rounded off value should be the same as that of the specified value in this Subsection.

This Page has been Intentionally left blank

Important Explanatory Note for Users of this NBCS

In any Part/Section of this NBCS, where reference is made to **'good practice'** in relation to design, constructional procedures or other related information, and where reference is made to '**accepted standard'** in relation to material specification, testing, or other related information, the Indian Standards listed at the end of the Part/Section shall be used as a guide to the interpretation.

At the time of publication, the editions indicated in the standards were valid. All standards are subject to revision and parties to agreements based on any Part/Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

In the list of standards given at the end of a Subsection, the number appearing within parentheses in the first column indicates the number of the reference of the standard in the Part/Section.

For example:

a) Good practices [C-3A(1)] refers to the Indian Standard(s) give at serial number (1) of the list of standards given at the end of this Part C/Subsection 3A, that is, IS 707 : 2011 'Timber technology and utilization of wood, bamboo and cane — Glossary of terms (*third revision*)'.

NATIONAL BUILDING CONSTRUCTION STANDARDS

PART C STRUCTURAL DESIGN

SECTION 3 TIMBER AND BAMBOO: 3A TIMBER

1 SCOPE

1.1 This NBCS (Part C/Subsection 3A) covers the general principles involved in the design of structural timber in buildings, including elements of structures connected by fasteners/fastening techniques.

1.2 This shall not be interpreted to prevent the use of material or methods of design or construction not specifically mentioned herein; and the methods of design may be based on analytical and engineering principles, or reliable test data, or both, that demonstrate the safety and serviceability of the resulting structure. The classification of timber into strength groups should not be interpreted as preventing the use of design data desired for a particular timber or grade of timber on the basis of reliable tests.

2 TERMINOLOGY

For the purpose of this Subsection, the following definitions and those given in the accepted standard [C-3A(1)], shall apply.

2.1 Structural Purpose Definitions

2.1.1 *Beam*, *Built-up Laminated* — A beam made by joining layers of timber together with mechanical fastenings, so that the grain of all layers is essentially parallel.

2.1.2 *Beam*, *Glued-Laminated* — A beam made by bonding layers of veneers or timber with an adhesive, so that grain of all laminations is essentially parallel.

2.1.3 *Bressummer* — A beam, across broad opening, sustaining super structure.

2.1.4 *Diaphragm*, *Structural* — A structural element of large extent placed in a building as a wall, or roof, and made use of to resist horizontal forces such as wind or earthquakes-acting parallel to its own plane.

2.1.5 *Duration of Load* — Period during which a member or a complete structure is stressed as a consequence of the loads applied.

NOTE — Timber is stronger under loads of brief duration than under permanently applied loads.

2.1.6 *Edge Distance* — The distance measured perpendicular to grain from the centre of the connector to the edge of the member.

2.1.7 *End Distance* — The distance measured parallel to grain of the member from the centre of the connector to the closest end of timber.

2.1.8 *Finger Joint* — End joint formed by machining a number of similar, tapered, symmetrical fingers in the ends of timber member, which are then bonded together.

2.1.9 *Finger Jointed Timber* — Timber containing adhesively bonded finger joints spaced at manufacturer specified minimum spacing.

2.1.10 *Fundamental or Ultimate Stress* — The stress which is determined on small clear specimen of timber, in accordance with accepted standards [C-3A(2)]; and does not take into account the effect of naturally occurring characteristics and other factors.

2.1.11 *Glue* — A substance capable of holding materials together by surface attachment.

2.1.12 *Glued Laminated* (*Glulam*) — A wood structural element comprising of sawn wood lamination bonded together with adhesives and in which the grains of all laminations are parallel longitudinally.

2.1.12.1 *Glued laminated*, *horizontally* — Glued laminated timber where gluing planes are perpendicular to the largest dimension of the transverse section, that is, in cross-wise direction.

2.1.12.2 *Glued laminated*, *vertically* — Glued laminated timber where gluing planes are perpendicular to the smallest dimension of the transverse section.

2.1.13 *Inside Location* — Position in buildings in which timber remains continuously dry or protected from weather.

2.1.14 *Isoptera* — An order of social insects consisting of the termites.

2.1.15 *Lamella Roof* — A roof or frame, made up of relatively short members, called lamellas, forming a network of framing timbers. This network forms a barrel-like structure of mutually braced and stiffened units, arching over the building between supports, and together with the sheathing forms a diaphragm for resistance of vertical and lateral loads.

2.1.16 *Laminations* — Thin elements of wood of appreciable width and length which, when superimposed on each other and fastened together with their grains essentially parallel make up cross section of considerable depth or width.

2.1.17 *Laminated Veneer Lumber* — A structural composite made by laminating veneers, 1.5 mm to 4.2 mm thick, with suitable adhesive and with the grain of veneers in successive layers aligned along the longitudinal (length) dimension of the composite.

2.1.18 *Latewood* — The portion of the wood that is formed in the later part of growth season and consists of thicker walled cells.

2.1.19 *Loaded Edge Distance* — The distance measured from the centre to the edge towards which the load induced by the connector acts, and the unloaded edge distance is the one opposite to the loaded edge.

2.1.20 *Location* — A term generally referred to as exact place where a timber is used in building.

2.1.21 *Mechanically Laminated* — A wood structural element comprising of laminations which are not glued but which are held together with mechanical fastenings such as nails or bolts and in which all laminations have the grains approximately parallel longitudinally.

2.1.22 *Outside Location* — Position in buildings in which timbers are occasionally subjected to wetting and drying as in the case of open sheds and outdoor exposed structures.

2.1.23 *Permissible Stress* — Stress obtained by applying factor of safety to the ultimate stress.

2.1.24 *Sandwich*, *Structural* — A layered construction comprising a combination or relatively high-strength facing material intimately bonded to and acting integrally with a low density core material.

2.1.25 *Spaced Column* — Two column sections adequately connected together by glue, bolts, screws or otherwise.

2.1.26 *Stressed Skin* — A form of construction in which the outer skin, in addition to its normal functioning of providing a surface covering, acts integrally with the framing members contributing to the strength of the unit as a whole.

2.1.27 *Structure*, *Permanent* — Structural units in timber which are constructed for a long duration and wherein adequate protection and design measures have initially been incorporated to render the structure serviceable for the required life.

2.1.28 *Structure*, *Temporary* — Structures which are erected for a short period, such as hutments at project sites, for rehabilitation, temporary defence constructions, exhibition structures, etc.

2.1.29 *Structural Element* — The component timber members and joints which make up a resulting structural assembly.

2.1.30 *Structural Grades* — Grades defining the maximum size of strength reducing natural characteristics (knots, sloping grain, etc) deemed permissible in any piece of structural timber within designated structural grade classification.

2.1.31 *Structural Timber* — Timber in which strength is related to the anticipated in-service use as a controlling factor in grading and selection and/or stiffness.

2.1.32 *Stud* — One of a series of slender wood structural members placed vertically as supporting members in a wall partition, or similar structural unit.

2.1.33 *Termite* — An insect of the order *Isoptera* which may burrow in the wood or wood products of a building for food or shelter.

2.1.34 *Wet Location* — Position in buildings in which timbers are almost continuously damp or wet in contact with the earth or water, such as piles and timber foundations.

2.2 Definitions of Defects in Timber

2.2.1 *Check* — A separation of fibres extending along the grain which is confined to one face of a piece of wood.

2.2.2 *Compression Wood* — Abnormal wood which is formed on the lower sides of branches and inclined stems of coniferous trees. It is darker and harder than normal wood but relatively low in strength for its weight. It can be usually identified by wide eccentric growth rings with abnormally high proportion of growth latewood.

2.2.3 *Dead Knot* — A knot in which the layers of annual growth are not completely intergrown with those of the adjacent wood. It is surrounded by pitch or bark. The encasement may be partial or complete.

2.2.4 *Decay or Rot* — Disintegration of wood tissue caused by fungi (wood destroying) or other micro-organisms.

2.2.5 *Decayed Knot* — A knot softer than the surrounding wood and containing decay.

2.2.6 *Diameter of Knot* — The maximum distance between the two points farthest apart on the periphery of a round knot, on the face on which it becomes visible. In the case of a spike or a splay knot, the maximum width of the knot visible on the face on which it appears shall be taken as its diameter.

2.2.7 *Discolouration* — A change from the normal colour of the wood which does not impair the strength of the wood.

2.2.8 *Knot* — A branch base or limb embedded in the tree or timber by natural growth.

2.2.9 *Knot Hole* — A hole left as a result of the removal of a knot.

2.2.10 *Live Knot* — A knot free from decay and other defects, in which the fibres are firmly intergrown with those of the surrounding wood. (*Synonyms:* 'Intergrown knot'; *cf.* 'Dead knot')

2.2.11 *Loose Grain* (*Loosened Grain*) — A defect on a flat sawn surface caused by the separation or raising of wood fibres along the growth rings; *cf.* 'Raised grain'.

2.2.12 *Loose Knot* — A knot that is not held firmly in place by growth or position, and that cannot be relied upon to remain in place; *cf.* 'Tight knot'.

2.2.13 *Mould* — A soft vegetative growth that forms on wood in damp, stagnant atmosphere. It is the least harmful type of fungus, usually confined to the surface of the wood.

2.2.14 *Pitch Pocket* — Accumulation of resin between growth rings of coniferous wood as seen on the cross-section.

2.2.15 *Sap Stain* — Discolouration of the sapwood mainly due to fungi.

2.2.16 *Sapwood* — The outer layer of log, which in the growing tree contain living cells and food material. The sapwood is usually lighter in colour and is readily attacked by insects and fungi.

2.2.17 *Shake* — A partial or complete separation between adjoining layers of tissues as seen in end surfaces.

2.2.18 *Slope of Grain* — The inclination of the fibres to the longitudinal axis of the member.

2.2.19 *Sound Knot* — A tight knot free from decay, which is solid across its face and at least as hard as the surrounding wood.

2.2.20 *Split* — A crack extending from one face of a piece of wood to another and runs along the grain of the piece.

2.2.21 *Tight Knot* — A knot so held by growth or position as to remain firm in position in the piece of wood; *cf.* 'Loose knot'.

2.2.22 *Wane* — The original rounded surface of a tree remaining on a piece of converted timber.

2.2.23 *Warp* — A deviation in sawn timber from a true plane surface or distortion due to stresses causing departure from a true plane.

2.2.24 *Worm Holes* — Cavities caused by worms.

3 SYMBOLS

For the purpose of this Subsection, the following letter symbols shall have the meaning indicated against each:

a = Projected area of bolt in main member (t' x d_3), mm^2

B = Width of the beam, mm

C = Concentrated load, N

D = Depth of beam, mm

D_1 = Depth of beam at the notch, mm

D_2 = Depth of notch, mm

d = Dimension of least side of column, mm

d_1 = Least overall width of box column, mm

d_2 = Least overall dimension of core in box column, mm

d_3 = Diameter of bolt, mm

d_f = Bolt-diameter factor

E = Modulus of elasticity in bending, N/mm^2

e = Length of the notch measured along the beam span from the inner edge of the support to the farthest edge of the notch, mm

F = Load acting on a bolt at an angle to grain, N

f_{ab} = Calculated bending stress in extreme fibre, N/mm^2

f_{ac} = Calculated average axial compressive stress, N/mm^2

f_{at} = Calculated axial tensile stress, N/mm^2

f_b = Permissible bending stress on the extreme fibre, N/mm^2

f_c = Permissible stress in axial compression, N/mm^2

f_{cn} = Permissible stress in compression normal (perpendicular) to grain, N/mm^2

f_{cp} = Permissible stress in compression parallel to grain, N/mm^2

$f_{c\theta}$ = Permissible compressive stress in the direction of the line of action of the load, N/mm^2

f_t = Permissible stress in tension parallel to grain, N/mm^2 [extreme fibre stress in bending-tension (f_b) is safe practical estimate of tensile strength due to mode of failure in beams]

H = Horizontal shear stress, N/mm^2

I = Moment of inertia of a section, mm^4

K = Coefficient in deflection depending upon type and criticality of loading on beam

K_1 = Modification factor for change in slope of grain

K_2 = Modification factor for change in duration of loadings

K_3, K_4, K_5, K_6 = Form factors

K_7 = Modification factor for bearing stress

K_8 = Constant equal to $0.584\sqrt{\frac{E}{f_{cp}}}$

K_9 = Constant equal to $\frac{\pi}{2}\sqrt{\frac{UE}{5q\,f_{cp}}}$

K_{10} = Constant equal to $0.584\sqrt{\frac{2.5E}{f_{cp}}}$

l or L = Span of a beam or truss, mm

M = Maximum bending moment in beam, N-mm

N = Total number of bolts in the joint

n = Shank diameter of the nail, mm

P = Load on bolt parallel to grain, N

p_1 = Ratio of the thickness of the compression flange to the depth of the beam

Q = Static moment of area above or below the neutral axis about neutral axis, mm^3

q = Constant for particular thickness of plank

q_1 = Ratio of the total thickness of web or webs to the overall width of the beam

R = Load on bolt perpendicular (normal) to grain, N

S = Unsupported overall length of column, mm

t = Nominal thickness of planks used in forming box type column, mm

t' = Thickness of main member, mm

U = Constant for a particular thickness of the plank

V = Vertical end reaction or shear at a section, N

W = Total uniform load, N

x = Distance from reaction to load, mm

y = Factor determining the value of form factor K_4

δ = Deflection at middle of beam, mm

θ = Angle of load to grain direction

Z = Section modulus of beam, mm^3

λ_1 = Percentage factor for t'/d_3 ratio, parallel to grain

λ_2 = Percentage factor for t'/d_3 ratio, perpendicular to grain

4 MATERIALS

4.1 Species of Timber

The species of timber recommended for structural purposes are given in Table 1 along with their permissible stresses and properties. For information on mechanical properties of certain foreign timber species, reference may be made to Annex A.

Table 1 Safe Permissible Stresses for the Species of Timber

[*Clauses* 4.1, 4.2, 4.7.2(b), 5.4.1, 5.4.2, 5.4.2.2, 6.5.8.3.1(b), 10.2.3 *and* 15.3]

NOTE — Any other species (including foreign species) of timber may be classified into Group A, B, or C based on their safe permissible stresses and other relevant properties, corresponding to the classification table provided for given Indian timber species. The assignment of a timber species to a specific group may be determined through standardized testing and evaluation of mechanical properties, including strength, durability and density, in accordance with the applicable test methods and criteria specified in accordance with accepted standards [C-3A(2)].

[1] Classification for preservation based on durability tests, etc.

Class:

I Average life more than 120 months;
II Average life 60 months and above but less than 120 months; and
III Average life less than 60 months.

[2] Treatability Grades:

a Heartwood easily treatable;
b Heartwood treatable, but complete penetration not always obtained; in case where the least dimension is more than 60 mm;
c Heartwood only partially treatable;
d Heartwood refractory to treatment; and
e Heartwood very refractory to treatment, penetration of preservative being practically nil even from the ends.

[3] Classifications based on seasoning behaviour of timber and refractoriness with respect to cracking, splitting and drying rate:

A Highly refractory (slow and difficulty to season free from surface and end cracking);
B Moderately refractory (may be seasoned free from surface and end cracking within reasonably short periods, given a little protection against rapid drying conditions); and
C Non-refractory may be rapidly seasoned free from surface and end-cracking even in the open air and sun. If not rapidly dried, they develop blue stain and mould on the surface.

[4] Species thus marked and tested from other localities show higher strength to enable their categorization in higher group.

For Example:

i) Sal tested from West Bengal, Bihar, Uttar Pradesh and Assam can be classified as Group `A' species.
ii) Haldu tested from Bihar can be classified as Group `B' species.
iii) Morus laevigate (Bole) of Assam can be classified in Group `B' species.

4.1.1 *Grouping*

Species of timber recommended for constructional purposes are classified in three groups on the basis of their strength properties, namely, modulus of elasticity (E) and extreme fibre stress in bending-tension (f_b).

The characteristics of these groups are as given below:

a) *Group A* — E above 12.6 kN/mm^2 and f_b above 18.0 N/mm^2.

b) *Group B* — E above 9.8 kN/mm^2 and up to 12.6 kN/mm^2 and f_b above 12.0 N/mm^2 and up to 18.0 N/mm^2.

c) *Group C* — E above 5.6 kN/mm^2 and up to 9.8 kN/mm^2 and f_b above 8.5 N/mm^2 and up to 12.0 N/mm^2.

NOTE — Modulus of elasticity given above is applicable for all locations and extreme fibre stress in bending is for inside location.

4.1.2 Timber species may be identified in accordance with good practice [C-3A(3)].

4.2 The general characteristics like durability, treatability and seasoning of the species are also given in Table 1. Species of timber other than those recommended in Table 1 may be used, provided the basic strength properties are determined and found in accordance with **4.1.1**.

NOTE — For obtaining basic stress figures of the unlisted species, reference may be made to the Forest Research Institute, Dehradun.

4.3 The permissible lateral strength (in double shear) of mild steel common wire nail shall be as given in Table 2 and Table 3 for different species of timber.

4.4 Moisture Content in Timber

The permissible moisture content of timber for various positions in buildings shall be as given in Table 4.

NOTES

1 Nails of 3.55 mm (9 SWG) diameter are most commonly used. The above values can also be used for 4 mm (8 SWG) diameter 100 mm long nails.

2 The values in Newton (N) are approximate converted values from kgf. For exact conversion the value is 1 kgf = 9.806 65 N.

3 Preboring of nail-jointed timber construction is desirable and shall be done in accordance with good practice as in, **6.2.2** and Table 3 of [C-3A(7)].

NOTES

1 Nails of 5.00 mm diameter are most commonly used.

2 The values in Newton (N) are approximate converted values from kgf. For exact conversion the value is 1 kgf = 9.806 65 N.

3 Preboring of nail-jointed timber construction is desirable and shall be done in accordance with good practice as in, **6.2.2** and Table 3 of [C-3A(7)].

Table 4 Permissible Percentage Moisture Content Values

(*Clause* 4.4)

Sl No.	Use	Zones (*see* Note)			
		I	II	III	IV
(1)	(2)	(3)	(4)	(5)	(6)
i)	Structural elements	12	14	17	20
ii)	Doors and windows:				
	a) 50 mm and above in thickness	10	12	14	16
	b) Thinner than 50 mm	8	10	12	14
iii)	Flooring strips for general purposes	8	10	10	12
iv)	Flooring strips for tea gardens	12	12	14	16

NOTE — The country has been broadly divided into the following four zones based on the humidity variations in the country:

a) Zone I — Average annual relative humidity less than 40 percent;

b) Zone II — Average annual relative humidity 40 percent to 50 percent;

c) Zone III — Average annual relative humidity 50 percent to 67 percent; and

d) Zone IV — Average annual relative humidity more than 67 percent.

For detailed zonal classification in the country, tolerances, etc, reference may be made to good practice [C-3A(4)].

4.5 Sawn Timber

4.5.1 *Sizes*

Preferred cut sizes of timber for use in structural components shall be as given in Table 5, Table 6 and Table 7.

Table 5 Preferred Cut Sizes of Structural Timber for Roof Trusses (Span from 3 m to 20 m)

(*Clause* 4.5.1)

Sl No.	Thickness mm	Width mm

viii)	60	–	–	60	80	100	120	160	200	240
ix)	80	–	–	–	80	100	120	160	200	240

NOTE — Preferred lengths of timber: 0.5 m, 1 m, 1.5 m, 2 m, 2.5 m and 3 m.

4.5.2 *Tolerances*

Permissible tolerances in measurements of cut sizes of structural timber shall be as follows:

a) For width and thickness:
  1) Up to and including 100 mm : $+3\ -\ 0\ mm$
  2) Above 100 mm : $+6\ -\ 3\ mm$
b) For length : $+10\ -\ 0\ mm$

4.6 Grading of Structural Timber

4.6.1 Cut sizes of structural timber shall be graded, after seasoning, into three grades based on permissible defects given in Table 8:

a) Select grade;
b) Grade I; and
c) Grade II.

Table 8 Permissible Defects for Cut Sizes of Timber for Structural Use

(*Clauses* 4.6.1 *and* 4.6.2.2)

All dimensions in millimetres.

Sl No.	Defects	Select Grade	Grade I	Grade II
(1)	(2)	(3)	(4)	(5)
i)	Wane	Shall be permissible at its deepest portion up to a limit of 1/8 of the width of the surface on which it occurs	Shall be permissible at its deepest portion up to a limit of 1/6 of the width of the surface on which it occurs	Shall be permissible at its deepest portion up to a limit of 1/4 of the width of the surface on which it occurs
ii)	Worm holes	Other than those due to powder post beetles are permissible	Other than those due to powder post beetles are permissible	Other than those due to powder post beetles are permissible
iii)	Slope of grain	Shall not be more than 1 in 20	Shall not be more than 1 in 15	Shall not be more than 1 in 12
iv)	Live knots:

4.6.2 The prohibited defects given in **4.6.2.1** and permissible defects given in **4.6.2.2** shall apply to structural timber.

4.6.2.1 *Prohibited defects*

Loose grains, splits, compression wood in coniferous species, heartwood rot, sap rot, crookedness, worm holes made by powder post beetles and pitch pockets shall not be permitted in all the three grades.

4.6.2.2 *Permissible defects*

Defects to the extent specified in Table 8 shall be permissible.

NOTE — Wanes are permitted provided they are not combined with knots and the reduction in strength on account of the wanes is not more than the reduction with maximum allowable knots.

4.6.3 *Location of Defects*

The influence of defects in timber is different for different locations in the structural element. Therefore, these should be placed during construction in such a way so that they do not have any adverse effect on the members, in accordance with the accepted standard [C-3A(5)].

4.7 Suitability

4.7.1 *Suitability in Respect of Durability and Treatability for Permanent Structures*

There are two choices as given in **4.7.1.1** and **4.7.1.2**.

4.7.1.1 *First choice*

The species shall be any one of the following:

a) Untreated heartwood of high durability. Heartwood if containing more than 15 percent sap wood, may need chemical treatment for protection;

b) Treated heartwood of moderate and low durability and Class ‘a’ and Class ‘b’ treatability;

c) Heartwood of moderate durability and Class ‘c’ treatability after pressure impregnation; and

d) Sapwood of all classes of durability after thorough treatment with preservative.

4.7.1.2 *Second choice*

The species of timber shall be heartwood of moderate durability and Class ‘d’ treatability.

4.7.2 *Choice of Species for Load-Bearing Temporary Structures or Semi-Structural Components at Construction Site*

The species shall be any one of the following:

a) Heartwood of low durability and Class ‘e’ treatability; or

b) The species whose durability and/or treatability is yet to be established, as listed in Table 1.

4.8 Fastenings

All structural members shall be framed, anchored, tied and braced to develop the strength and rigidity necessary for the purposes for which they are used. Allowable stresses or loads on joints and fasteners shall be determined in accordance with recognized principles. Common mechanical fastenings are of bar type such as nails and spikes, wood screws and bolts, and timber connectors including metallic rings or wooden disc-dowels. Chemical fastenings include synthetic adhesives for structural applications.

NOTE — Synthetic adhesives are able to achieve for timber what welding has achieved for steel.

4.9 Requirements of Structural Timber

The various other requirements of structural timber for use in building shall be in accordance with the accepted standard [C-3A(5)].

5 PERMISSIBLE STRESSES

5.1 Fundamental stress values of different groups of timber are determined on small clear specimen according to good practices [C-3A(2)]. These values are then divided by the appropriate factors of safety to obtain the permissible stresses. Values of these factors of safety for different strength characteristics are as per the relevant table of the accepted standard [C-3A(5)].

5.2 The permissible stresses for Groups A, B and C for different locations applicable to Grade I structural timber shall be as given in Table 9 provided that the following conditions are satisfied:

a) The timbers should be of high or moderate durability and be given the suitable treatment where necessary;

b) Timber of low durability shall be used after proper preservative treatment to good practice [C-3A(6)]; and

c) The loads should be continuous and permanent and not of impact type.

5.3 The permissible stresses (excepting E) given in Table 9 shall be multiplied by the following factors to obtain the permissible stresses for other grades provided that the conditions laid down in **5.2** are satisfied:

a) For select grade timber : 1.16

b) For Grade II timber : 0.84

5.3.1 When low durability timbers are to be used [*see* **5.2(b)**] on outside locations, the permissible stresses for all grades of timber, arrived at by **5.2** and **5.3** shall be multiplied by 0.80.

5.4 Modification Factors for Permissible Stresses

5.4.1 *Due to Change in Slope of Grain*

When the timber has not been graded and has major defects like slope of grain, knots and checks or shakes but not beyond permissible value, the permissible stress given in Table 1 shall be multiplied by modification factor K_1 for different slopes of grain as given in Table 10.

Table 9 Minimum Permissible Stress Limits (in N/mm^2) in Three Groups of Structural Timbers (For Grade I Material)

(*Clauses* 5.2 *and* 5.3)

Sl No. (1)	Strength Character (2)	Location of Use (3)	Group A (4)	Group B (5)	Group C (6)
i)	Bending and tension along grain	Inside[1]	18.0	12.0	8.5
ii)	Shear[2]:				
	a) Horizontal	All locations	1.05	0.64	0.49
	b) Along grain	All locations	1.5	0.91	0.70
iii)	Compression parallel to grain	Inside[1]	11.7	7.8	4.9
iv)	Compression perpendicular to grain	Inside[1]	4.0	2.5	1.1
v)	Modulus of elasticity ($\times 10^3$ N/mm^2)	All locations and grade	12.6	9.8	5.6

Table 10 Modifications Factor K_1 to Allow for Change in Slope of Grain

(*Clause* 5.4.1)

Sl No.	Slope	Modification Factor K_1	
		Strength of Beams, Joists and Ties	Strength of Posts or Columns
(1)	(2)	(3)	(4)
i)	1 in 10	0.80	0.74
ii)	1 in 12	0.90	0.82
iii)	1 in 14	0.98	0.87
iv)	1 in 15 and flatter	1.00	1.00

NOTE — For intermediary slopes of grains, values of modification factor may be obtained by interpolation.

---

[1] For working stresses for other locations of use, that is, outside and wet, generally factors of 5/6 and 2/3 are applied.

[2] The values of horizontal shear to be used only for beams. In all other cases shear along grain to be used.

5.4.2 *Due to Duration of Load*

For different durations of design load, the permissible stresses given in Table 1 shall be multiplied by the modification factor K_2 given in Table 11.

NOTE — The strength properties of timber under load are time-dependent.

Table 11 Modification Factor K_2, for Change in Duration of Loading

(*Clause* 5.4.2)

Sl No. (1)	**Duration of Loading** (2)	**Modification Factor K_2** (3)
i)	Continuous (normal)	1.0
ii)	Two months	1.15
iii)	Seven days	1.25
iv)	Wind and earthquake	1.33
v)	Instantaneous or impact	2.00

5.4.2.1 The factor K_2 is applicable to modulus of elasticity when used to design timber columns, otherwise they do not apply thereto.

5.4.2.2 If there are several duration of loads (in addition to the continuous) to be considered, the modification factor shall be based on the shortest duration load in the combination, that is, the one yielding the largest increase in the permissible stresses, provided the designed section is found adequate for a combination of other larger duration loads.

NOTE — In any structural timber design for dead loads, snow loads and wind or earthquake loads, members may be designed on the basis of total of stresses due to dead, snow and wind loads using modification factor $K_2 = 1.33$ for the permissible stresses (*see* Table 1) to accommodate the wind load, that is, the shortest of duration and giving the largest increase in the permissible stresses. The section thus found is checked to meet the requirements based on dead loads alone with modification factor $K_2 = 1.00$.

5.4.2.3 Modification factor K_2 shall also be applied to allowable loads for mechanical fasteners in design of joints, when the wood and not the strength of metal determines the load capacity.

6 DESIGN CONSIDERATIONS

6.1 All structural members, assemblies or framework in a building, in combination with the floors, walls and other structural parts of the building shall be capable of sustaining, with due stability and stiffness the whole dead and imposed loadings as per Part C 'Structural Design, Section 1 Loads and Load Effects' of this NBCS, without exceeding the limits of relevant stresses specified in this Subsection.

6.2 Buildings shall be designed for all dead and imposed loads or forces assumed to come upon them during construction or use, including uplifts or horizontal forces from wind and forces from earthquakes or other loadings. Structural members and their connections shall be proportioned to provide a sound and stable structure with adequate strength and stiffness. Wooden components in construction generally include panels for sheathing and diaphragms, siding, beams, girder, columns, light framings, masonry wall and joist construction, heavy-frames, glued laminated structural members, structural sandwiches, prefabricated panels, lamella arches, portal frames and other auxiliary constructions.

6.3 Net Section

6.3.1 The net section is obtained by deducting from the gross sectional area of timber the projected area of all material removed by boring, grooving or other means at critical plane. In case of nailing, the area of the prebored hole shall not be taken into account for this purpose.

6.3.2 The net section used in calculating load carrying capacity of a member shall be at least net section determined as above by passing an imaginary plane or a series of connected planes transversely through the members.

6.3.3 Notches shall be in no case remove more than one quarter of the section.

6.3.4 In the design of an intermediate or a long column, gross section shall be used in calculating load carrying capacity of the column.

6.4 Loads

6.4.1 The loads shall conform to those given in Part C ‘Structural Design, Section 1 Loads and Load Effects’ of this NBCS.

6.4.2 The worst combination and location of loads shall be considered for design. Wind and seismic forces shall not be considered to act simultaneously.

6.5 Flexural Members

6.5.1 Such structural members shall be investigated for the following:

a) Bending strength;
b) Maximum horizontal shear;
c) Stress at the bearings; and
d) Deflection.

6.5.2 *Effective Span*

The effective span of beams and other flexural members shall be taken as the distance from face of supports plus one-half of the required length of bearing at each end except that for continuous beams and joists the span may be measured from centre of bearing at those supports over which the beam is continuous.

6.5.3 Usual formula for flexural strength shall apply in design:

$$f_{ab} = \frac{M}{Z} \leq f_b$$

6.5.4 *Form Factors for Flexural Members*

The following form factors shall be applied to the bending stress:

a) *Rectangular section* — For rectangular sections, for different depths of beams, the form factor K_3 shall be taken as:

$$K_3 = 0.81\left(\frac{D^2 + 89\,400}{D^2 + 55\,000}\right)$$

NOTE — Form factor (K_3) shall not be applied for beams having depth less than or equal to 300 mm.

b) *Box beams and I-beams* — For box beams and I-beams the form factor K_4 shall be obtained by using the formula:

$$K_4 = 0.8 + 0.8y\left(\frac{D^2 + 89\,400}{D^2 + 55\,000} - 1\right)$$

where

$$y = {p_1}^2\,(6 - 8p_1 + 3{p_1}^2)(1 - q_1) + q_1$$

c) *Solid circular cross sections* — For solid circular cross sections the form factor K_5 shall be taken as 1.18; and

d) *Square cross sections* — For square cross sections where the load is in the direction of diagonal, the form factor K_6 shall be taken as 1.414.

6.5.5 *Width*

The minimum width of the beam or any flexural member shall not be less than 50 mm or 1/50 of the span, whichever is greater.

6.5.6 *Depth*

The depth of beam or any flexural member shall not be taken more than three times of its width without lateral stiffening.

6.5.6.1 *Stiffening*

All flexural members having a depth exceeding three times its width or a span exceeding 50 times its width or both shall be laterally restrained from twisting or buckling and the distance between such restraints shall not exceed 50 times its width.

6.5.7 *Shear*

6.5.7.1 The following formulae shall apply:

a) The maximum horizontal shear, when the load on a beam moves from the support towards the centre of the span, and the load is at a distance of three to four times the depth of the beam from the support, shall be calculated from the following general formula:

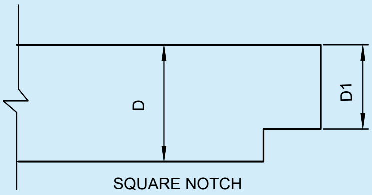
$$H = \frac{VQ}{Ib}$$

b) For rectangular beams:

$$H = \frac{3V}{2bD}$$

c) For notched beams, with tension notch at supports (*see* 6.5.7.3):

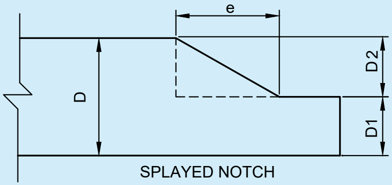
$$H = \frac{3VD}{2b{D_1}^2}$$



SQUARE NOTCH
(BOTTOM SIDE
NOTCHED)

d) For notched at upper (compression) face, where e > D:

$$H = \frac{3VD}{2bD_1}$$



SPLAYED NOTCH
(UPPER SIDE
NOTCHED)

e) For notched at upper (compression) face, where e < D:

$$H = \frac{3V}{2b\left[D - \left(\frac{D_2}{D}\right)e\right]}$$

6.5.7.2 For concentrated loads:

$$V = \frac{10C(l-x)(x/D)^2}{9l[2+(x/D)^2]} \quad and$$

For uniformly distributed loads:

$$V = \frac{W}{2}\left(1 - \frac{2D}{l}\right)$$

After arriving at the value of *V*, its value shall be substituted in the formula:

$$H = \frac{VQ}{Ib}$$

6.5.7.3 In determining the vertical reaction *V*, the following deductions in loads may be made:

a) Consideration shall be given to the possible distribution of load to adjacent parallel beams, if any;

b) All uniformly distributed loads within a distance equal to the depth of the beam from the edge of the nearest support may be neglected except in case of beam hanging downwards from a particular support; and

c) All concentrated loads in the vicinity of the supports may be reduced by the reduction factor applicable according to Table 12.

Table 12 Reduction Factor for Concentrated Loads in the Vicinity of Supports

[*Clause* 6.5.7.3(c)]

Sl No. (1)	**Distance of Load from the Nearest Support** (2)	**1.5 D or Less** (3)	**2 D** (4)	**2.5 D** (5)	**3 D or More** (6)
i)	Reduction factor	0.60	0.40	0.20	No reduction

NOTE — For intermediate distances, factor may be obtained by linear interpolation.

6.5.7.4 Unless the local stress is calculated and found to be within the permissible stress, flexural member shall not be cut, notched or bored except as follows:

a) Notches may be cut in the top or bottom neither deeper than one-fifth of the depth of the beam nor farther from the edge of the support than one-sixth of the span;

b) Holes not larger in diameter than one quarter of the depth may be bored in the middle third of the depth and length; and

c) If holes or notches occur at a distance greater than three times the depth of the member from the edge of the nearest support, the net remaining depth shall be used in determining the bending strength (*see* Fig. 1):

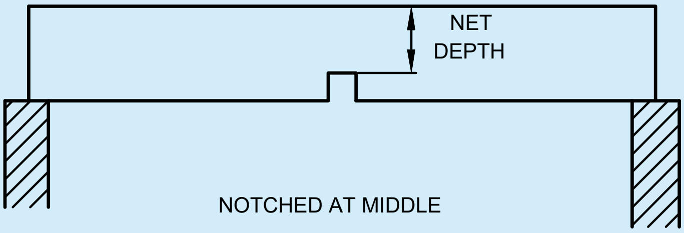


FIG. 1 NOTCHED BEAMS

6.5.8 *Bearing*

6.5.8.1 The ends of flexural members shall be supported in recesses which provide adequate ventilation to prevent dry rot and shall not be enclosed. Flexural members except roof timbers which are supported directly on masonry or concrete shall have a length of bearing of not less than 75 mm. Members supported on corbels, offsets and roof timbers on a wall shall bear immediately on and be fixed to wall-plate not less than 75 mm × 40 mm.

6.5.8.2 Timber joists or floor planks shall not be supported on the top flange of steel beams unless the bearing stress, calculated on the net bearing as shaped to fit the beam, is less than the permissible compressive stress perpendicular to the grain.

6.5.8.3 *Bearing stress*

6.5.8.3.1 *Length and position of bearing*

a) At any bearing on the side grain of timber, the permissible stress in compression perpendicular to the grain, f_{cn}, is dependent on the length and position of the bearing.

b) The permissible stresses given in Table 1 for compression perpendicular to the grain are also the permissible stresses for any length at the ends of a member and for bearings 150 mm or more in length at any other position.

c) For bearings less than 150 mm in length located 75 mm or more from the end of a member as shown in Fig. 2, the permissible stress may be multiplied by the modification factor K_7 given in Table 13.

d) No allowance need be made for the difference in intensity of the bearing stress due to bending of a beam.

e) The bearing area should be calculated as the net area after allowance for the amount of wane.

f) For bearings stress under a washer or a small plate, the same coefficient specified in Table 13 may be taken for a bearing with a length equal to the diameter of the washer or the width of the small plate.

g) When the direction of stress is at angle to the direction of the grain in any structural member, then the permissible bearing stress in that member shall be calculated by the following formula:

$$f_{c\theta} = \frac{f_{cp} \times f_{cn}}{f_{cp}\theta \ + f_{cn}\theta}$$

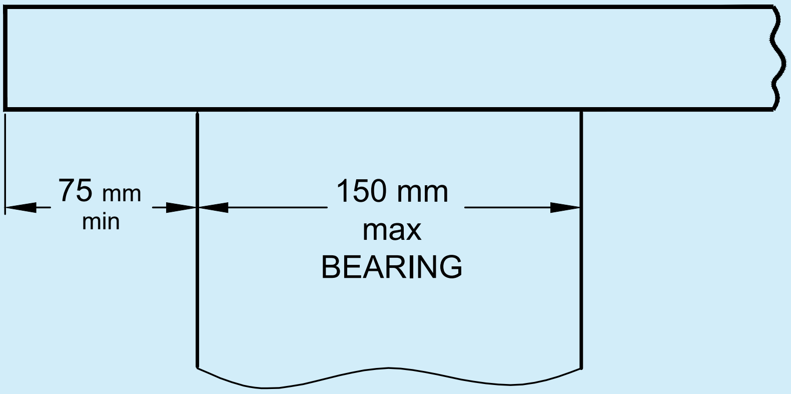

FIG 2. POSITION OF END BEARINGS

Table 13 Modification Factor K_7 for Bearing Stresses

[*Clauses* 6.5.8.3.1(c) *and* (f)]

Sl No.	Length of Bearing mm	15	25	40	50	75	100	150 or More
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)
i)	Modification factor, K_7	1.67	1.40	1.25	1.20	1.13	1.10	1.00

6.5.9 Purlin is a structural member, essentially a beam subjected to transverse loads and rests on the top chord of roof truss. Being under bi-axial bending, vertical loads are resolved into two components, that is, perpendicular to and parallel to roof slopes (*see* Fig. 3). The effect of normal and tangential components of the vertical load is worked out separately and the in fibre stress in bending, shall be the algebraic sum of both.

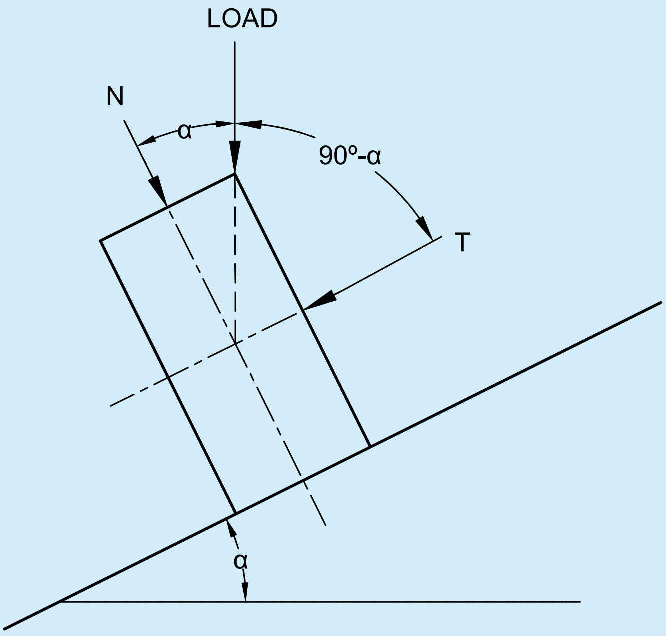

FIG. 3 PURLIN

6.5.10 *Deflection*

The deflection in the case of all flexural members supporting brittle materials like gypsum ceilings, slates, tiles and asbestos sheets shall not exceed 1/360 of the span. The deflection in the case of other flexural members shall not exceed 1/240 of the span and 1/150 of the freely hanging length in the case of cantilevers.

6.5.10.1 Usual formula for deflection shall apply*:*

$$\delta = \frac{KWL^3}{EI} \quad \text{(ignoring deflection due to shear strain)}$$

K-value = 1/3 for cantilevers with load at free end;
= 1/8 for cantilevers with uniformly distributed load;
= 1/48 for beams supported at both ends with point load at centre; and
= 5/384 for beams supported at both ends with uniformly distributed load.

6.5.10.2 In order to allow the effect of long duration loading on *E*, for checking deflection in case of beams and joists the effective loads shall be twice the dead load if timber is initially dry.

NOTE — The tendency of flexural members to acquire larger permanent deflections under long continued loadings has to be taken care of either by considering double the dead load in calculations of deflection or by giving a factor of safety to MOE.

6.5.10.3 Self weight of beam shall be considered in design.

6.6 Columns

NOTE — The formulae given are for columns with pin end conditions and the length shall be modified suitably with other end conditions.

6.6.1 *Solid Columns*

Solid columns shall be classified into short, intermediate and long columns depending upon their slenderness ratio (*S/d*) as follows:

a) *Short columns* — where *S/d* does not exceed 11;

b) *Intermediate columns* — where *S/d* is between 11 and K_8; and

c) *Long columns* — where *S/d* is greater than K_8.

6.6.1.1 For short columns, the permissible compressive stress shall be calculated as follows:

$$f_c = f_{cp}$$

6.6.1.2 For intermediate columns, the permissible compressive stress is calculated by using the following formula:

$$f_c = f_{cp}\left[1 - \frac{1}{3}\left(\frac{S}{K_8 d}\right)^4\right]$$

6.6.1.3 For long columns, the permissible compressive stress shall be calculated by using the following formula:

$$f_c = \frac{0.329E}{\left(\frac{S}{d}\right)^2}$$

6.6.1.4 In case of solid columns of timber, *S/d* ratio shall not exceed 50.

6.6.1.5 The permissible load on a column of circular cross section shall not exceed that permitted for a square column of an equivalent cross sectional area, where side of square is equal to 0.886 times the diameter.

6.6.1.6 For determining *S*/*d* ratio of a tapered column, such as for wooden poles, its least dimension shall be taken as the sum of the corresponding least dimensions at the small end of the column and one-third of the difference between this least dimension at the small end and the corresponding least dimension at the large end, but in no case shall the least dimension for the column be taken as more than one and a half times the least dimension at the small end. The induced stress at the small end of the tapered column shall not exceed the permissible compressive stress in the direction of grain.

6.6.2 *Built-up Columns*

6.6.2.1 *Box column*

Box columns shall be classified into short, intermediate and long columns as follows:

a) *Short columns* — where $\frac{S}{\sqrt{{d_1}^2+{d_2}^2}}$ is less than 8;

b) *Intermediate columns* — where $\frac{S}{\sqrt{{d_1}^2+{d_2}^2}}$ is between 8 and K_9; and

c) *Long columns* — where $\frac{S}{\sqrt{{d_1}^2+{d_2}^2}}$ is greater than K_9;

6.6.2.2 For short columns, the permissible compressive stress shall be calculated as follows:

$$f_c = q f_{cp}$$

6.6.2.3 For intermediate columns, the permissible compressive stress shall be obtained using the following formula:

$$f_c = q f_{cp}\left[1 - \frac{1}{3}\left(\frac{S}{K_9\sqrt{{d_1}^2 + {d_2}^2}}\right)^4\right]$$

6.6.2.4 For long columns, the permissible compressive stress shall be calculated by using the following formula:

$$f_c = \frac{0.329UE}{\left(\frac{S}{\sqrt{{d_1}^2 + {d_2}^2}}\right)^2}$$

6.6.2.5 The following values of *U* and *q*, depending upon plank thickness (*t*) in 6.6.2.3 and 6.6.2.4, shall be used for width of plank not greater than 5 times the plank thickness:

Sl No.	*t* mm	*U*	*q*
(1)	(2)	(3)	(4)
i)	25	0.80	1.00
ii)	50	0.60	1.00

6.6.3 *Spaced Columns*

6.6.3.1 The formulae for solid columns as specified in 6.6.1 are applicable to spaced columns with a restraint factor of 2.5 or 3, depending upon distances of end connectors in the column.

NOTE — A restrained factor of 2.5 for location of centroid group of fasteners at *S*/20 from end and 3 for location at *S*/10 to *S*/20 from end shall be taken.

6.6.3.2 For intermediate spaced column, the permissible compressive stress shall be:

$$f_c = f_{cp}\left[1 - \frac{1}{3}\left(\frac{S}{K_{10}d}\right)^4\right]$$

6.6.3.3 For long spaced columns, the permissible compressive stress shall be:

$$f_c = \frac{0.329E \times 2.5}{(S/d)^2}$$

6.6.3.4 For individual members of spaced columns, *S*/*d* ratio shall not exceed 80.

6.6.4 Compression members shall not be notched. When it is necessary to pass services through such a member, this shall be effected by means of a bored hole provided that the local stress is calculated and found to be within the permissible stress specified. The distance from the edge of the hole to the edge of the member shall not be less than one quarter of width of the face.

6.7 Tension Member (Ties)

The stress is axial tension parallel to grain of wood shall be calculated on the basis of net-section area which shall not exceed the safe permissible value in tension parallel to grain:

$$f_{at} = \frac{Maximum\ force\ prevailing}{Area\ of\ cross\ section} \leq f_t$$

6.8 Structural Members Subject to Bending and Axial Stresses

6.8.1 Structural members subjected both to bending and axial compression shall be designed to comply with the following:

$$\frac{f_{ac}}{f_c} + \frac{f_{ab}}{f_b} \text{ is not greater than 1}$$

6.8.2 Structural members subjected both to bending and axial tension shall be designed to comply with the following:

$$\frac{f_{at}}{f_t} + \frac{f_{ab}}{f_b} \text{ is not greater than 1}$$

6.9 Timber Roof Truss

Trusses are framed structures in which separate straight members are so arranged and connected at their ends that members form triangles. The external loads cause direct stresses in the members. Essentially a plane structure which is very stiff in the plane of the members but very flexible in every other direction. For members subjected to reversal of stresses, design has to be for one stress and tested for the other applied at the panel points. Eccentricity of meeting members at joint may result in the increased stresses in design.

7 DESIGN OF COMMON STEEL WIRE NAIL JOINTS

7.1 General

Nail jointed timber construction is suitable for light and medium timber framings (trusses, etc) up to 15 m spans. With the facilities of readily available materials and simpler workmanship in mono-chord and split-chord constructions, this type of fabrication has a large scope. Preboring of nail-jointed timber construction is desirable and shall be done in accordance with good practice as in, **6.2.2** and Table 3 of good practice [C-3A(7)].

7.2 Dimensions of Members

The dimension of an individual piece of timber (that is any single member) shall be within the range given below:

a) The minimum thickness of the main members in mono-chord construction shall be 30 mm;

b) The minimum thickness of an individual piece of members in split-chord construction shall be 20 mm for web members and 25 mm for chord members; and

c) The space between two adjacent pieces of timber shall be restricted to a maximum of 3 times the thickness of the individual piece of timber of the chord member. In case of web members, it may be greater for joining facilities.

7.3 No lengthening joint shall preferably be located at a panel point. Generally, not more than two, but preferably one, lengthening joint shall be permitted between the two panel points of the members.

7.4 Specification and Diameter of Nails

7.4.1 The nails used for timber joints shall conform to Part B 'Building Materials' of this NBCS. The nails shall be diamond pointed.

7.4.2 The diameter of nail shall be within the limits of one-eleventh to one-sixth of the least thickness of members being connected.

7.4.3 Where the nails are exposed to be saline conditions, common wire nails shall be galvanized.

7.5 Arrangement of Nails in the Joints

The end distances, edge distances and spacing of nails in a nailed joint should be such as to avoid undue splitting of the wood and shall not be less than those given in **7.5.1** and **7.5.2**.

7.5.1 *Lengthening Joints*

The requirement of spacing of nails in a lengthening joint shall be as given in Table 14 (*see also* Fig. 4):

Table 14 Spacing of Nails

(*Clause* 7.5.1)

Sl No.	Spacing of Nails	Type of Stress in the Joint	Requirement *Min*
(1)	(2)	(3)	(4)
i)	End distance	Tension compression	12 *n* 10 *n*
ii)	In direction of grain	Tension compression	10 *n* 5 *n*
iii)	Edge distance	–	5 *n*
iv)	Between row of nails perpendicular to the grain	–	5 *n*

NOTES

1 *n* is shank diameter of nails.

2 The 5*n* distance between rows perpendicular to the grain may be increased subject to the availability of width of the member keeping edge distance constant.

Fig. 6 Spacing of Nails at Node Joints where Members are Inclined to One Another

7.6 Penetration of Nails

7.6.1 For a lap joint when the nails are driven from the side of the thinner member, the length of penetration of nails in the thicker member shall be one and a half times the thickness of the thinner member subject to maximum of the thickness of the thicker member.

7.6.2 For butt joints the nails shall be driven through the entire thickness of the joint.

7.7 Design Considerations

7.7.1 Where a number of nails are used in a joint, the allowable load in lateral resistance shall be the sum of the allowable loads for the individual nails, provided that the centroid of the group of these nails lies on the axis of the member and the spacings conform to **7.5**. Where a large number of nails are to be provided at a joint, they should be so arranged that there are more of rows rather than more number of nails in a row.

7.7.2 Nails shall, as far as practicable, be arranged so that the line of force in a member passes through the centroid of the group of nails. Where this is not practicable, allowance shall be made for any eccentricity in computing the maximum load on the fixing nails as well as the loads and bending moment in the member.

7.7.3 Adjacent nails shall preferably be driven from opposite faces, that is, the nails are driven alternatively from either face of joint.

7.7.4 For a rigid joint, a minimum of 2 nails for nodal joints and 4 nails for lengthening joint shall be driven.

7.7.5 Two nails in a horizontal row are better than using the same number of nails in a vertical row.

7.7.6 The permissible lateral strength (in double shear) of mild steel common wire for different species of timber shall be as per **4.3**.

7.8 Special Consideration in Nail-Jointed Truss Construction

7.8.1 The initial upward camber provided at the centre of the lower chord of nail-jointed timber trusses shall be not less than 1/200 of the effective span for timber structures using seasoned wood and 1/100 for unseasoned or partially seasoned wood.

7.8.2 The total combined thickness of the gusset or splice plates on either side of the joint in a mono-chord type construction shall not be less than one and a half times the thickness of the main members subject to a minimum thickness of 25 mm of individual gusset plate.

NOTES

1 The allowable load or lateral strength values of nails shall be those as given in Table 2 and Table 3.

2 The strength data for joints given in the Subsection apply to gusset or splice or fish plates of solid wood; however, materials other than solid wood may be used for gusset when field tests are made and their strength requirements have been established.

7.8.3 The total combined thickness of all spacer blocks or plates or both including outer splice plates, at any joint in a split-chord type construction shall not be less than one and a half times the total thickness of all the main members at that joint.

7.9 Fabrication

The fabrication of nail-jointed timber construction shall be done in accordance with good practice [C-3A(7)].

8 DESIGN OF NAIL LAMINATED TIMBER BEAMS

8.1 Method of Arrangement

8.1.1 The beam shall be made up of 20 mm to 30 mm thick planks placed vertically with joints staggered in the adjoining planks with a minimum distance of 300 mm. The planks are laminated with the help of wire nails at regular intervals to take up horizontal shear developed in the beam besides keeping the planks in position (*see* Fig. 7).

8.1.2 The advantage in laminations lies in dimensional stability, possible dispersal of defects and better structural performance.

8.2 Sizes of Planks and Beams

8.2.1 The plank thickness for fabrication of nailed laminated beams recommended are 20 mm, 25 mm and 30 mm.

8.2.2 In case of nailed laminated timber beam the maximum depth and length of planks shall be limited to 250 mm and 2 000 mm, respectively.

8.2.3 In order to obtain the overall width of the beam, the number and thickness of planks to form vertical nailed laminated beams, and also type and size of wire nail shall be as mentioned in Table 15. The protruding portion of the nail shall be cut off or clenched across the grains.

8.3 Design Considerations

8.3.1 Nail laminated beams shall be designed in accordance with **6** and provisions in the good practice [C-3A(8)].

8.3.1.1 The deflection in the case of nailed laminated timber beams, joists, purlins, battens and other flexural members supporting brittle materials like gypsum, ceiling slates, tiles and asbestos sheets shall not exceed 1/480 of the span. The deflection in case of other flexural members shall not exceed 1/360 of the span in the case of beams and joists and 1/225 of the freely hanging length in case of cantilevers.

8.3.2 Permissible lateral strength of diamond pointed mild steel wire nails shall be as given in Table 2 and Table 3 for Indian species of timber, which shall apply to nails that have their points cut flush with the faces. For nails clenched across the grains the strength may be increased by 20 percent over the values for nails with points cut flush.

FIG. 7 PLAN AND ELEVATION OF A TYPICAL NAILED LAMINATED TIMBER BEAM

8.3.3 *Arrangement of Nails*

8.3.3.1 A minimum number of four nails in a vertical row at regular interval not exceeding 75 mm to take up horizontal shear as well as to keep the planks in position shall be used. Near the lengthening joints of the planks this distance may, however, be limited to 50 mm instead of 75 mm.

8.3.3.2 Shear shall be calculated at various points of the beam and the number of nails required shall be accommodated within the distance equal to the depth of the beam, with a minimum of 4 nails in a row at a standard spacing as shown in Fig. 8.

8.3.3.3 If the depth of the beam is more, then the vertical intermediate spacing of nails may be increased proportionately.

8.3.3.4 If the nails required at a point are more than that can be accommodated in a row, then these shall be provided lengthwise of the beam within the distance equal to the depth of the beam at standard lengthwise spacing.

8.3.3.5 For nailed laminated beam minimum depth of 100 mm for 3.55 mm and 4 mm diameter nails and 125 mm for 5 mm diameter nails shall be provided.

8.4 Fabrication

The fabrication of nailed laminated timber beams shall be done in accordance with good practice [C-3A(8)].

9 DESIGN OF BOLTED CONSTRUCTION JOINTS

9.1 General

Bolted joints suit the requirements of prefabrication in small and medium span timber structures for speed and economy in construction. Bolt jointed construction units offer better facilities as regards to workshop ease, mass production of components, transport convenience and re-assembly at site of work particularly in defence sector for high altitudes and far off situations. Designing is mainly influenced by the species, size of bolts, moisture conditions and the inclination of loadings to the grains. In principle, bolted joints follow the pattern of riveted joints in steel structures.

9.2 Design Considerations

9.2.1 Bolted timber construction shall be designed in accordance with **6**. The concept of critical section, that is, the net section obtained by deducting the projected area of bolt-holes from the cross-sectional area of member is very important for the successful design and economy in timber.

9.2.2 *Bolt Bearing Strength of Wood*

The allowable load for a bolt in a joint consisting of two members (single shear) shall be taken as one half the allowable loads calculated for a three member joint (double shear) for the same t'/d_3 ratio. The percentage of safe working compressive stress of timber on bolted joints for different t'/d_3 ratios shall be as given in Table 16.

Table 16 Percentage of Safe Working Compressive Stress of Timber for Bolted Joints in Double Shear

9.2.2.1 Where a number of bolts are used in a joint, the allowable loads shall be the sum of the allowable loads for the individual bolts.

9.2.2.2 The factors for different bolt diameter used in calculating safe bearing stress perpendicular to grain in the joint shall be as given in Table 17.

9.2.3 *Dimensions of Members*

a) The minimum thickness of the main member in mono-chord construction shall be 40 mm;

b) The minimum thickness of side members shall be 20 mm and shall be half the thickness of main members; and

c) The minimum individual thickness of spaced member in split-chord construction shall be 20 mm and 25 mm for webs and chord members, respectively.

9.2.4 *Bolts and Bolting*

a) The diameter of bolt in the main member shall be so chosen to give larger slenderness (t'/d_3) ratio of bolt;

b) There shall be more number of small diameter bolts rather than small number of large diameter bolts in a joint;

c) A minimum of two bolts for nodal joints and four bolts for lengthening joints shall be provided;

d) There shall be more number of rows rather than more bolts in a row;

e) The bolt holes shall be of such diameter that the bolt can be driven easily; and

f) Washers shall be used between the head of bolt and wood surface as also between the nut and wood.

Table 17 Bolt Diameter Factor

(*Clause* 9.2.2.2)

Sl No.	Diameter of Bolt mm	Diameter Factor (d_f)
(1)	(2)	(3)

ii)	10	3.60
iii)	12	3.35
iv)	16	3.15
v)	20	3.05
vi)	22	3.00
vii)	25	2.90

9.3 Arrangement of Bolts

9.3.1 The following spacings in bolted joints shall be followed (*see* Fig. 9):

a) *Spacing of bolts in a row* — For parallel and perpendicular to grain loading = 4 d_3;

b) *Spacing between rows of bolts*:

   1) *For perpendicular to grain loading* — 2.5 d_3 to 5 d_3 (2.5 d_3 for t'/d_3 ratio of 2 and 5 d_3 for t'/d_3 ratio of 6 or more. For ratios between 2 and 6 the spacing shall be obtained by interpolation.

   2) *For parallel to grain loading* — At least (N - 4) d_3 with a minimum of 2.5 d_3. Also governed by net area at critical section which should be 80 percent of the total area in bearing under all bolts.

c) *End distance* — 7d_3 for softwoods in tension, 5 d_3 for hardwoods in tension and 4 d_3 for all species in compression; and

d) *Edge distance*:

   1) For parallel to grain loading 1.5 d_3 or half the distance between rows of bolts, whichever is greater.

   2) For perpendicular to grain loading, the loaded edge distance shall be at least 4 d_3.

9.3.2 For inclined members, the spacing given above for perpendicular and parallel to grain of wood may be used as a guide and bolts arranged at the joint with respect to loading direction.

9.3.3 The bolts shall be arranged in such a manner so as to pass the centre of resistance of bolts through the intersection of the gravity axis of the members.

9.3.4 Staggering of bolts shall be avoided as far as possible in case of members loaded parallel to grain of wood. For loads acting perpendicular to grain of wood, staggering is preferable to avoid splitting due to weather effects.

9.3.5 *Bolting*

The bolt holes shall be bored or drilled perpendicular to the surface involved. Forcible driving of the bolts shall be avoided which may cause cracking or splitting of members. A bolt hole of 1.0 mm oversize may be used as a guide for preboring.

9.3.5.1 Bolts shall be tightened after one year of completion of structure and subsequently at an interval of two to three years.

9.4 Outline for Design of Bolted Joints

Allowable load on one bolt (unit bearing stress) in a joint with wooden splice plates shall not be greater than value of P, R, F as determined by one of the following equations:

a) *For loads parallel to grain*:

$$P = f_{cp}\ a\ \lambda_1$$

b) *For loads perpendicular to grain*:

$$R = f_{cn}\ a\ \lambda_2\ d_f$$

c) *For loads at an angle to grain*:

$$F = \frac{PR}{P\sin^2\theta + R\cos^2\theta}$$

FIG. 9B SPACING OF BOLTS AT NODE JOINTS

FIG. 9 TYPICAL SPACING OF BOLTS IN STRUCTURAL JOINTS

9.5 Fabrication

The fabrication of bolt jointed construction shall be in accordance with good practice [C-3A(9)].

To meet the specific requirements of ‘all-timber construction’ for structures where chemical corrosion of steel elements is a problem, and in order to erect anti-magnetic laboratories, sheds, etc, design should be made on the basis of mild steel bolt joints with the following reductions for timber bolts and bamboo pins:

Allowable safe working load per hardwood timber bolt = 66 percent of the safe working load per mild steel bolt

Safe working load per solid bamboo pin = 56 percent of the working load per mild bamboo per steel bolt

10 DESIGN OF TIMBER CONNECTOR JOINTS

10.1 In large span structures, the members have to transmit very heavy stresses requiring stronger jointing techniques with metallic rings or wooden disc-dowels. Improvised metallic ring connector is a split circular band of steel made from mild steel pipes. This is placed in the grooves cut into the contact faces of the timber members to be joined, the assembly being held together by means of a connecting bolt (*see* Fig. 10).

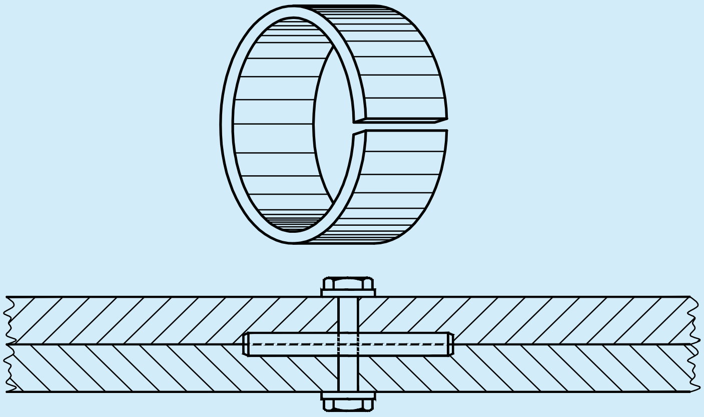

FIG. 10 SPLIT RING CONNECTOR

10.1.1 *Dimensions of Members*

Variation of thickness of central (main) and side members affect the load carrying capacity of the joint. The thickness of main member shall be at least 57 mm and that of side member 38 mm with length and width of members governed by placement of connector at joint.

The metallic connector shall be so placed that the loaded edge distance is not less than the diameter of the connector and the end distance not less than 1.75 times the diameter on the loaded side.

10.1.2 *Design Considerations*

The primary stresses in a split ring connector joint under tension are illustrated in Fig. 11. The shaded areas represent the part of wood in shear, compression and tension. Related formulae for the same are given in **10.1.2.1**.

For fabrication of structural members, a hole of the required size of the bolt is drilled into the member and a groove is made on the contact faces of the joint.

Theoretical safe loads in design shall be corroborated with sample tests done in accordance with a [C-3A(10)].

NOTE — A pilot study on determination of strength of improvised split ring connector joint in a compression test for a specific design problem conducted using *Mesua ferrea* (Mesua), yielded the data which is given below, for guidance:

Sl No.	*No. and Diameter of Ring Used in a Joint*		*No. and Size of Bolt Used in a Joint*		*Side Member*		*Central Member*		*Load Direction with respect to Grains of Wood*	*End Distance*	*Inter-mediate Distance*	*Load Per Pair of Connector*

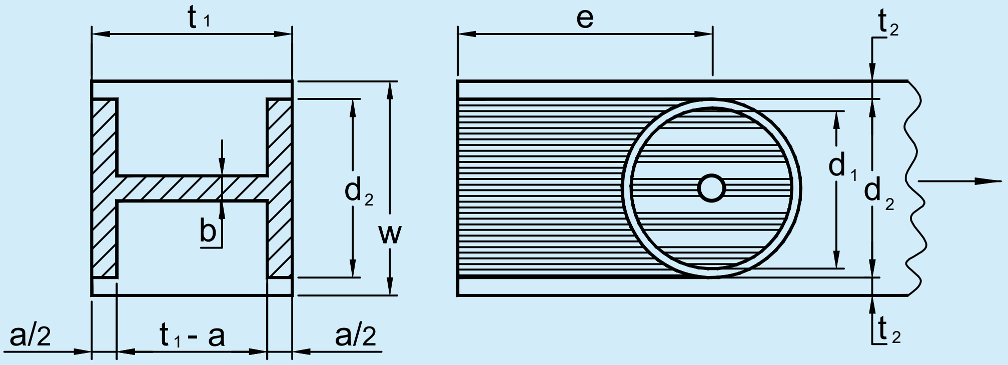
11A VERTICAL STRESS DITRBUTION



11B HORIZONTAL STRESS DITRBUTION

NOTE — Symbols are exclusive to this figure.

FIG. 11 STRESS DISTRIBUTION IN A SPLIT RING CONNECTOR

10.1.2.1 Strength of joint is controlled by one or another or combination of three properties:

a) Tension area (*see* Fig. 11A):

$$t_1 w - \left[2\left(\frac{a d_2}{2}\right) + b(t_1 - a)\right]$$

b) Compression area (*see* Fig. 11B):

$$2\left(\frac{a d_2}{2}\right) + b(t_1 - a)$$

c) Shear area (*see* Fig. 11B):

1) *Within core* : $2\left(\frac{\pi {d_1}^2}{4}\right)$

2) *Below core* : $2\left[d_2 e - \frac{1}{2}\left(\frac{\pi {d_2}^2}{4}\right) + 2\left(\frac{ae}{2}\right)\right]$

where

d_1 = inside diameter of connector;
t_1 = thickness of member;
w = width of member;
a = depth of connector;
d_2 = outside diameter of connector;
b = diameter of bolt;
e = end distance from centre of connector to end of member; and
t_2 = thickness of metal.

10.2 Wooden Disc-Dowel

10.2.1 It is a circular hardwood disc generally tapered each way from the middle so as to form a double conical frustum. Such a disc is made to fit into preformed holes (recesses), half in one member and the other half in another, the assembly being held by one mild steel bolt through the centre of the disc to act as a coupling for keeping the jointed wooden members from spreading apart.

As timber always fails by shearing or crushing in front of bolts, the function of disc-dowel incorporated in the joint is to distribute the shearing stresses on a larger area of wood so as to transmit the full amount of stresses.

10.2.2 *Dimensions of Members*

The thickness of dowel may vary from 25 mm to 35 mm and diameter from 50 mm to 150 mm. The diameter of dowel shall be 3.25 to 3.50 times the thickness.

The edge clearance shall range from 12 mm to 20 mm as per the size of the dowel. The end clearance shall be at least equal to the diameter of dowel for joints subjected to tension and three-fourth the diameter for compression joints. Disc dowel shall be turned from radial (quarter sawn) planks of seasoned material.

10.2.3 *Choice of Species*

Wood used for making dowels shall be fairly straight grained, free from excessive liability to shrink and warp, and retain shape well after seasoning and having high shear strength. Species recommended include:

a) Babul;
b) Dhaman;
c) Irul;
d) Sissoo;
e) Rose wood;
f) Sandal;
g) Axle-wood;
h) Padauk; and
j) Yon.

NOTE – Data on the above species are as per Table 1.

10.2.4 *Design Considerations*

The forces on dowel in a lap joint and butt joint are illustrated in Fig. 12. Dowel is subjected to shearing at the mid-section, and compression along the grain at the bearing surfaces. For equal strength in both the forces, formula equations are given in the Fig. 12 to determine the size of dowel.

The making of wooden discs may present some problems in the field, but they may be made in small workshop to the specifications of the designer. This is also economically important. Once the wood fittings are shop tailored and made, the construction process in the field is greatly simplified.

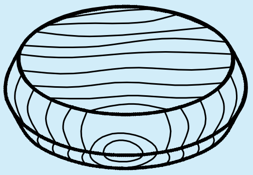
Theoretical safe loads in design shall be confirmed through sample tests.

NOTE — Some experimental studies have indicated the following safe loads, in kN, for dowels bearing parallel to the grain, which are given here for guidance only.

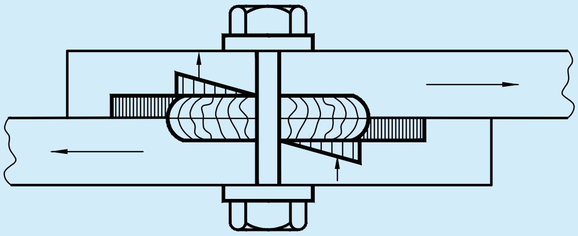
Sl No.	*Species*		*Safe Loads for Dowels Bearing Parallel to the Grain, in kN* *Size of Dowel* (mm)					
	Members	Dowels	62 × 25	75 × 25	87 × 25	100 × 31	112 × 37	125 × 37
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)
i)	Sal	Babul	6.671	9.810	13.342	17.805	22.269	27.566
ii)	Sal	Sissoo	5.346	7.554	10.251	13.342	16.922	20.895

10.2.4.1 Rigid specifications regarding use of particular planks for fabrication of wooden disc-dowels, and the specific alignment of grains to be in line with grains of members forming the joint, can be relaxed. Application of appropriate factors in design of such joints whatever be the angle of load and members, etc, would eliminate risks involved by providing 60 percent more number of dowels at a joint. Thus, decrease the calculated load per dowel to 60 percent.

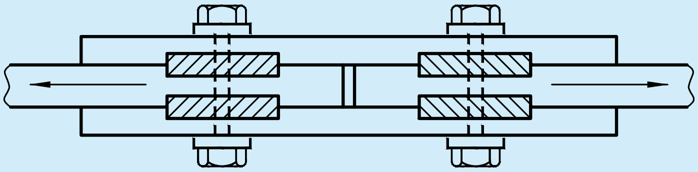
10.2.4.2 Analysis of variance for safe load in case of dowel joints made with MS bolt, timber bolt, bamboo pin as joiners showed no significant difference. Thus, the concept of 'all-timber construction' hold good for chemical industries where corrosion due to acid fumes is a recurring problem.



DOWEL



LAP JOINT



BUTT JOINT

Lap joint — Bolt in simple tension due to clockwise turning moment on dowel.

Butt joint — No tilting moment in dowel due to balancing effect [dowels are in shear (no bending, shearing and tensile stress on bolts)]

Size of dowel for equal strength in both shearing and bearing.

$$\frac{\pi d^2}{4} \times S = d \times \frac{t}{2} \times c$$

where

d = mid diameter of the dowel;

t = thickness of dowel;

s = safe working stress in shear along grain; and

c = safe compressive stress along grain.

NOTE — Symbols are exclusive to this figure.

FIG. 12 DISTRIBUTION OF FORCES IN DOWEL JOINT

11 GLUED LAMINATED CONSTRUCTION

11.1 Developments in the field of synthetic adhesive have brought gluing techniques within the range of engineering practice. Timber members of larger cross-sections and long lengths can be fabricated from small sized planks by the process of glulam. The term glued laminated timber construction as applied to structural members refers to various laminations glued together, either in straight or curved form, having grain of all laminations essentially parallel to the length of the member.

11.1.1 *Choice of Glue*

The adhesive used for glued laminated assembly are ‘gap filling’ type. A ‘filler’ in powder form is introduced in the adhesive. Structural adhesives are supplied either in powder form to which water is added or in resin form to which a hardener or catalyst is added. For choice of glues, reference may be made to good practice [C-3A(11)]. However, it is important that only boiling water proof (BWP) grade adhesives shall be used for fabrication of glulam in tropical, high humid climates like India.

11.1.2 *Manufacturing Schedule*

In absence of a systematic flow-line in a factory, provisions of intermediate technology shall be created for manufacturing structural elements. The schedule involves the following steps:

a) Drying of planks;
b) Planning;
c) End-jointing by scarfs or fingers;
d) Machining of laminations;
e) Setting up dry assembly of structural unit;
f) Application of glue;
g) Assembly and pressing the laminations;
h) Curing the glue lines, as specified; and
j) Finishing, protection and storage.

11.1.3 The information with regard to block shear test results on glued timber joints is given in Table 18.

NOTE — The information given in the above table is based on the block shear test results on glued timber joints conducted on the basis of BS 4169 : 1970 'Specification for manufacture of glued-laminated timber structural members' (since revised and subsequently superseded by BS EN 392 : 1995, BS EN 391 : 1995, BS EN 386 : 1995) and the failures observed with regard to glue line and the wood. Ultimate shear stresses for 29 species were studied keeping design glue shear strength at least one-third of ultimate. Glue mixing, spreading, pressing and curing was done as per the instructions of adhesive manufacturers under improvised techniques locally developed. Sustainable period before delamination of glue bond (urea formaldehyde) in weathering tests was recorded for over a year. Limited number of species survived with most of them failed within a period of six months.

11.2 Design of Glued Laminated Beams

11.2.1 *General*

Glued laminated structural members shall be fabricated only where there are adequate facilities for accurate sizing and surfacing of planks, uniform application of glue, prompt assembly, and application of adequate pressure and prescribed temperature for setting and curing of the glue. Design and fabrication shall be in accordance with established engineering principles and good practice. A glued laminated beam is a straight member made from a number of laminations assembled both ways either horizontally or vertically (*see* Fig. 13). While vertical laminations have limitations in restricting the cross section of a beam by width of the plank, horizontally laminated section offers wider scope to the designer in creating even the curved members. Simple straight beams and joists are used for many structures from small domestic rafters or ridges to the light industrial structures.

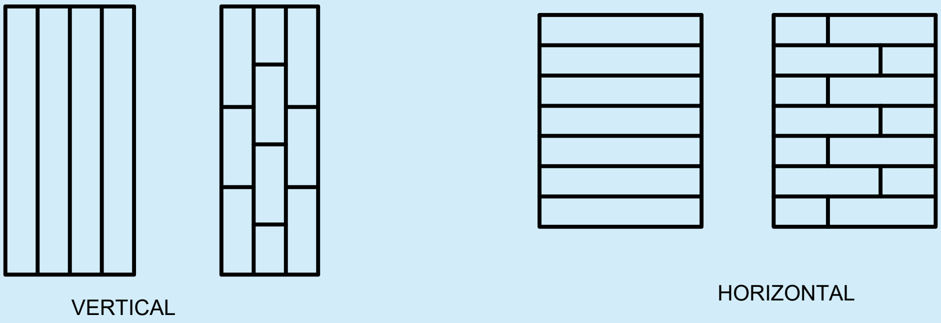

FIG. 13 POSSIBLE ORIENTATION OF PLANKS IN GLULAM

11.2.2 *Design*

The design of glue laminated wood elements shall be in accordance with good engineering practice and shall take into consideration the species and grade of timber used, presence of defects, location of end joints in laminations, depth of beams and moisture contents expected while in service. Beams of large spans shall be designed with a suitable camber to assist in achieving the most cost effective section where deflection governs the design. The strength and stiffness of laminated beams is often governed by the quality of outer laminations. Glued laminated beams can be tapered to follow specific roof slopes across a building and/or to commensurate with the varying bending moments. Glulam allows the engineers to mix grades within a beam. Obviously, the lower tensile portion should be of high grade material. However, it is possible to incorporate a considerable volume of lower grade material near the neutral axis taking care of the horizontal shear stress. Similarly, species can also be mixed depending upon the modulus of elasticity.

Straight beams that will be simply supported should be cambered during fabrication to allow for deflection due to dead loads over a period of time. The usual camber is $\frac{span}{400}$, unless otherwise specified.

11.2.2.1 *Design outline for horizontally laminated beams*

A design outline for horizontal laminated beams, specifying data required and a possible solution is given below.

a) *Data required:*

  1) Span (L), loads including self weight of beam (W), species of timber, thickness of lamination proposed; and
  2) Mechanical properties of timber species (permissible extreme fibre stress in bending-tension, permissible compressive stress perpendicular to grain, modulus of elasticity, permissible shear stress parallel to grain).

  The permissible shear stress at the glue line is at least the same as the permissible shear stress parallel to grain of the species in design, unless otherwise tested.

b) *Solution:*

1) Let, b = width of beam, and d = depth of beam, for lateral stability, $b : d = 1 : 4$ (*say*).
2) Determine bending moment on the basis of span, loading and support conditions (say, $WL/8$ for beams with both ends fixed).
3) Also, bending moment (M) = Bending stress (f_b) × Section modulus (Z):

$$\text{Therefore, } M = f_b \times \frac{bd^2}{6} = \frac{WL}{8}$$

$$\text{or } bd^2 = \frac{WL}{8} \times \frac{6}{f_b}$$

4) From bd^2 obtained at (c) and $b : d$ assumed at (a), arrive at appropriate values of b and d.
5) Check for deflection of beam. Since dead load is for long term, double this for deflection check, that is:

$$W = (2 \times \textit{Dead load}) + \textit{Imposed load}$$

Deflection is to be limited to the specified requirement, say 0.003 of span.

Substituting values of b and d from (d) and $I (= bd^3/12)$ in the formula for deflection, perform check against the limit for deflection.

6) Decide the number and thickness of laminations for the required depth of section.

11.2.3 *Material*

Laminating boards shall not contain decay, knots or other strength reducing characteristics in excess of those sizes or amounts permitted by specifications. The moisture content shall approach that expected in service and shall in no case exceed 15 percent at the time of gluing. The moisture content of individual laminations in a structural member shall not differ by more than 3 percent at the time of gluing. Glue shall be of type suitable for the intended service of a structural member.

11.2.4 *Fabrication/Manufacture*

In order to assure a well-bonded and well-finished member of true shape and size, all equipment, end-jointing, glue spread, assembly, pressing, curing or any other operation in connection with the manufacture of glued structural members shall be in accordance with the available good practices and as per glue manufacturers' instructions as applicable.

11.2.4.1 End joints shall be scattered in adjacent laminations, which shall not be located in very highly stressed outer laminations.

11.2.5 *Testing*

Quality control, inspection and testing during production is essential to structural glulam. Special attention needs to be given to members exposed to weather.

For examining the quality of glue and its relative strength namely species of timber in glued laminated construction, it is necessary to conduct block shear and other related tests in accordance with accepted standard [C-3A(11)]. Structural loading tests on prototype sizes provide information on the strength properties, stiffness or rigidity against deflection of a beam. Information on different strength functions as obtained from such indigenous tests carried out on laminated timber beams are given in Table 19, for guidance in design.

Table 19 Laminated Timber Beams — Structural Bending Test Under Three Point Loading

(*Clause* 11.2.5)

12 LAMINATED VENEER LUMBER

12.1 Certain reconstituted lignocellulosic products with fibre oriented along a specific direction have been developed and are being adopted for load bearing applications. Laminated veneer lumber is one such product developed as a result of researches in plantation grown species of wood. Density of laminated veneer lumber ranges from 600 kg/m^3 to 750 kg/m^3 which is manufactured in accordance with accepted standard [C-3A(12)].

12.1.1 *Dimensions*

Sizes of laminated veneer lumber composite shall be inclusive of margin for dressing and finishing unless manufactured to order. The margin for dressing and finishing shall not exceed 3 mm in the width and thickness and 12 mm in the length.

12.1.2 *Permissible Defects*

a) Jointing gaps	:	Not more than 3 mm wide, provided they are well staggered in their spacing and position between the successive plies;
b) Slope of grain	:	Not exceeding 1 in 10 in the face layers;
c) Tight knot	:	Three numbers up to 25 mm diameter in 1 m^2 provided they are spaced 300 mm or more apart; and
d) Warp	:	Not exceeding 1.5 mm per metre length.

12.1.3 *Strength Requirements*

The strength requirements for laminated veneer lumber shall be as per Table 20.

Table 20 Requirements of Laminated Veneer Lumber

(*Clause* 12.1.3)

Sl No. (1)	Properties (2)	Requirement (3)
i)	Modulus of rupture, N/mm^2, *Min*	50

vi)	Screw holding power:	
	a) Edge (N), *Min*	2 300
	b) Face (N), *Min*	2 700
vii)	Thickness swelling in 2 h water soaking (percent), *Max*	3

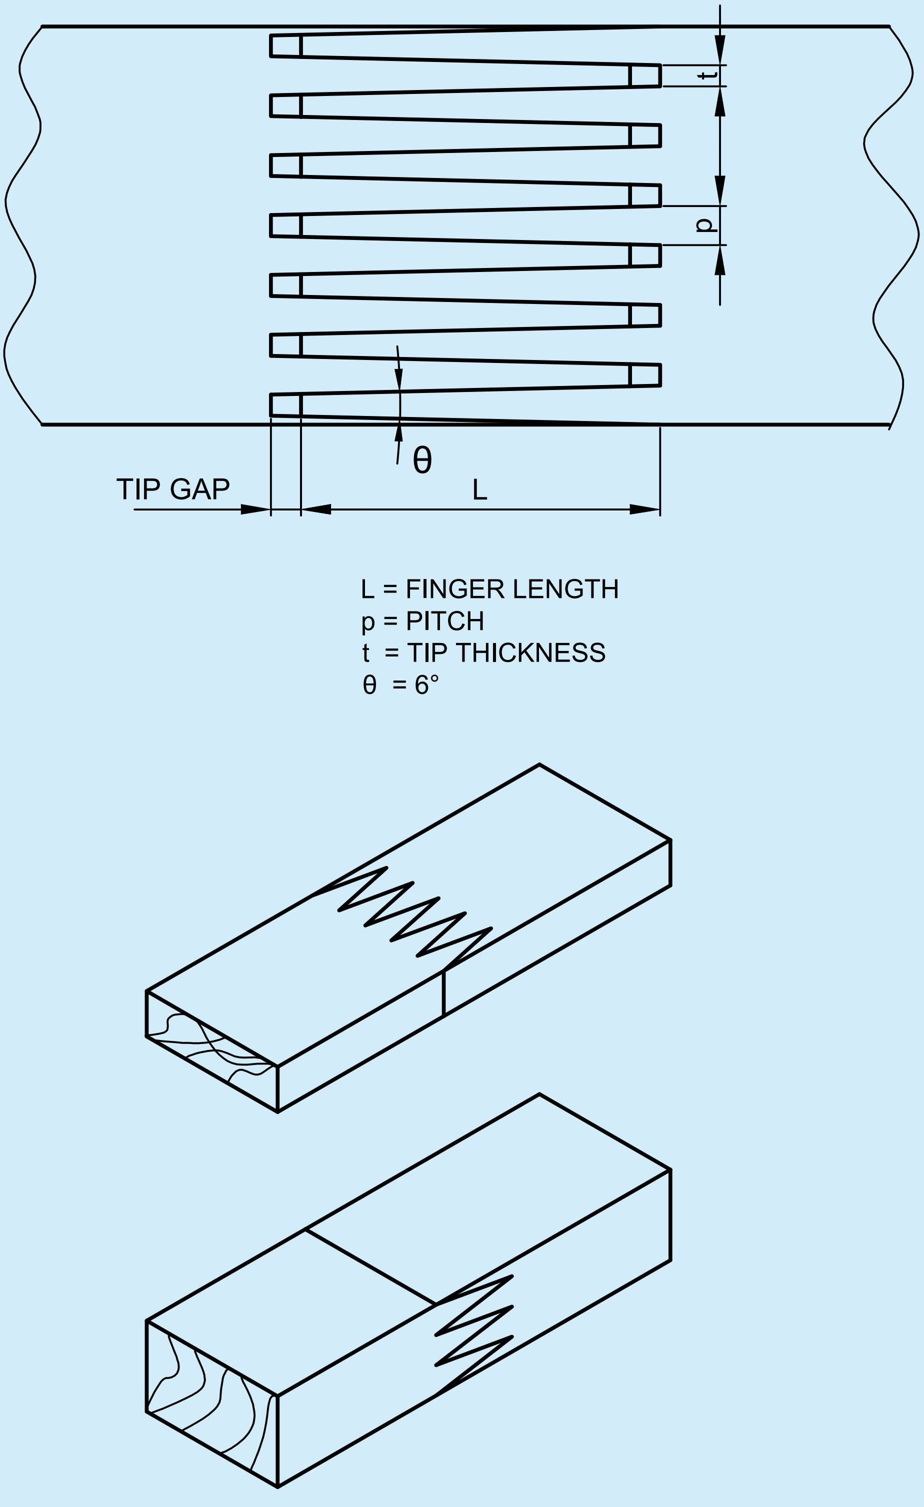
13 GLUED FINGER JOINTS

13.1 Finger joints are glued joints connecting timber members end-to-end (*see* Fig. 14). Such joints shall be produced by cutting profiles (tapered projections) in the form of v-shaped grooves to the ends of timber planks or scantling to be joined, gluing the interfaces and then mating the two ends together under pressure. Finger joints provide long lengths of timber, ideal for upgrading timber by permitting removal of defects, minimizing warping and reducing wastage by avoiding short off-cuts. To improve the long-term durability and performance of glued finger joints, the timber used should be well-seasoned to maintain dimensional stability. Additional protective treatments may be required for finger-jointed timber used in outdoor or high-moisture environments to prevent decay and degradation of the adhesive bonds.

13.1.1 In finger joints the glued surfaces are on the side grain rather than on the end grain and the glue line is stressed in shear rather in tension.

13.1.1.1 The fingers can be cut from edge-to-edge or from face-to-face. The difference is mainly in appearance, although bending strength increases if several fingers share the load. A joist is slightly stronger with edge-to-edge finger joints and a plank is stronger with face-to-face finger joint. The choice of adhesive should consider the wood species being used, as different timber species may exhibit varying adhesive compatibility. For example, denser species may require stronger bonding adhesives, while lower-density woods may work well with more flexible adhesives. Testing of specific adhesives with the wood species used is recommended to ensure optimal joint strength and performance.

13.1.1.2 For structural finger jointed members for interior dry locations, adhesives based on melamine formaldehyde cross linked polyvinyl acetate (PVA) are suited. For high humid and exterior conditions, phenol formaldehyde and resorcinol formaldehyde type adhesives are recommended. Proper adhesives should be selected in consultation with the designer and adhesive manufacturers and assessed in accordance with accepted standard [C-3A(11)]. The environmental impact of adhesives used in finger-jointed construction should also be considered. Where possible, the use of low- volatile organic compounds (VOC) or environmentally friendly adhesives should be promoted, particularly in indoor applications, to reduce emissions and promote healthier indoor air quality.



L = FINGER LENGTH
p = PITCH
t = TIP THICKNESS
θ = 6°

ORIENTATION OF FINGER JOINTS

FIG. 14 TYPICAL FINGER JOINT GEOMETRY

13.1.2 *Manufacturing Process*

In the absence of sophisticated machinery, the finger joints shall be manufactured through intermediate technology with the following steps:

a) Drying of wood;

b) Removal of knots and other defects;

c) Squaring the ends of the laminating planks;

d) Cutting the profile of finger joint in the end grain;

e) Applying adhesives on the finger interfaces;

f) Pressing the joint together at specified pressure;

g) Curing of adhesive line at specified temperature; and

h) Planing of finger-jointed planks for smooth surface.

For higher precision and productivity, modern manufacturing facilities could implement computer numerical control (CNC) machines for cutting finger joints. Automation helps achieve consistent profile geometry, improves the quality of adhesive application, and reduces the margin for human error during production.

13.1.3 *Strength*

Strength of finger joints depends upon the geometry of the profile for structural purpose; this is generally 50 mm long, 12 mm pitch.

13.1.3.1 The strength properties of glued finger joints are given in Table 21 for information and guidance in design.

13.1.3.2 Tip thickness shall be as small as practically possible.

14 STRUCTURAL USE OF PLYWOOD

Unlike sawn timber, plywood is a layered panel product comprising veneers of wood bonded together with adjacent layers usually at right angles. As wood is strongest when stressed parallel to grain, and weak perpendicular to grain, the lay up or arrangement of veneers in the panel determines its properties. When the face grain of the plywood is parallel to the direction of stress, veneers parallel to the face grain carry almost all the load. Some information/guidelines for structural use of plywood which should be manufactured in accordance with accepted standards [C-3A(13)] are given in **14.1** to **14.3**.

14.1 The plywood has a high strength to weight ratio and is dimensionally stable material available in sheets of a number of thicknesses and construction. Plywood can be sawn, drilled and nailed with ordinary wood working tools. The glues used to bond these veneers together are derived from synthetic resins which are set and cured by heating. The properties of adhesives can determine the durability of plywood.

14.2 In glued plywood construction, structural plywood is glued to timber resulting in highly efficient and light structural components like web beams (I and box sections) (*see* Fig. 15 and Fig. 16) stressed skin panels (*see* Fig. 17) used for flooring and walling and pre-fabricated houses, cabins, etc. Gluing can be carried out by nail gluing techniques with special clamps. High shear strength of plywood in combination with high flexural strength and stiffness of wood result in structures characterized by high stiffness for even medium spans. Plywood can act as web transmitting shear stress in web bearing or stressed skin or sandwich construction. The effective moment of inertia of web beam and stressed skin construction depends on modular ratio that is, *E* of wood to *E* of plywood.

Table 21 Strength Characteristics of Glued Finger Joints

P – Cold setting phenolic glue with hardener
L$_1$ – Finger length 38 mm
L$_2$ – Finger length 50 mm
L$_3$ – Finger length 62 mm
C – Control (unjointed specimen)

NOTE — The information given in the above table is based on the tests conducted on glued finger joints of varying lengths/pitch with two types of adhesives.

14.3 Structural plywood is also very efficient as cladding material in wood frame construction such as houses. This type of sheathing is capable of resisting racking due to wind and earthquake forces. Structural plywood has been widely used as diaphragm (horizontal) as in roofing and flooring in timber frame construction. It has been established that 6 mm thick plywood can be used for sheathing and even for web and stressed skin construction, 9 mm to 12 mm thick plywood is suitable for beams, flooring diaphragms, etc. Phenol formaldehyde (PF) and PRF adhesive are suitable for fabrication of glued plywood components. 6 mm to 12 mm thick structural plywood can be very well used as nailed or bolted gussets in fixing members of trusses or lattice girders or trussed rafters.

Normally, scarf joints are used for fixing plywood to required length and timber can be joined by using either finger or scarf joints. Arch panels, folded plates, shelves are other possibilities with this technique.

15 TRUSSED RAFTER

15.1 General

A roof truss is essentially a plane structure which is very stiff in the plane of the members, that is the plane in which it is expected to carry loads, but very flexible in every other direction. Thus, it can virtually be seen as a deep, narrow girder liable to buckling and twisting under loads. In order, therefore, to reduce this effect, eccentricity of loading and promote prefabrication for economy, low-pitched trussed rafters are designed with bolt ply/nail ply joints. Plywood as gussets, besides being simple have inherent constructional advantage of grain over solid wood for joints and a better balance is achievable between the joint strength and the member strength.

Trussed rafters are light weight truss units spaced at close centres for limited spans to carry different types of roof loads. They are made from timber members of uniform thickness fastened together in one plane. The plywood gussets may be nailed or glued to the timber to form the joints. Conceptually a trussed rafter is a triangular pin jointed system, traditionally meant to carry the combined roof weight, cladding services and wind loads. There is considerable scope for saving timber by minimizing the sections through proper design without affecting structural and functional requirements.

Trussed rafters are required to be supported only at their ends so that there is no need to provide load bearing internal walls, purlins, etc. In comparison with traditional methods of construction they use less timber and considerably reduce on-site labour and mass production of reliable units can be carried out under workshop controls.

Additional consideration may include:

a) *Climatic Suitability* — Trussed rafters should be designed with consideration for India's diverse climatic zones. Timber species suitable for humid, dry and coastal regions should be preferred to prevent issues related to swelling, shrinkage, or decay due to moisture variations;

b) *Use of Local Timber Species* — Indian species such as Teak (*Tectona grandis*), Sal (*Shorea robusta*), Neem (*Azadirachta indica*), and other durable hardwoods should be prioritized. The use of locally available plantation-grown timber helps reduce transportation costs and supports sustainability; and

c) *Fire and Termite Resistance* — Due to the prevalence of termites in many regions of India, timber rafters should be treated with appropriate termite-resistant chemicals. Similarly, the risk of fire in construction should be mitigated through the application of fire-retardant coatings.

15.2 Design

15.2.1 The design may be based on the use of Group ‘C’ species of standard grade timber in accordance with good practice [C-3A(7)] for nail jointed timber construction. As the strength and stiffness of any framing depends upon efficiency of joints, design calls for proper size and number of fasteners, their spacings and thickness of gusset plates for transfer of stress from one member to the other.

Trussed rafter shall be designed to sustain the dead and imposed loads specified in Part C ‘Structural Design, Section 1 Loads and Load Effects’ of this NBCS and the combinations expected to occur. Extra stresses/deflections during handling, transportation and erection shall be taken care of. Structural analysis, use of load-slip and moment, rotation characteristics of the individual joints may be used if feasible. Alternatively, the maximum direct force in a member may be assessed to be given by an idealized pin-jointed framework, fully loaded with maximum dead and imposed load in the combination in which they may reasonably be expected to occur.

NOTE — Some trussed rafters with plywood gusseted joint, span 6 m, designed in *Pinus roxburghii* (Chir) were tested in prototypes at Forest Research Institute, Dehradun for structural adequacy as under, in accordance with accepted standards [C-3A(14)]:

a) Destructive test (short-term); and

b) Proof test (long-term).

Results demonstrated an apparent factor at safety of 4 and actual factor of safety of 3. Deflection was well within the allowable deflection at design load. A pre-camber of 1/240 of span at the bottom chord was recommended.

15.3 Timber

The species of timber including plantation grown species which can be used for trussed rafter construction and permissible stresses thereof shall be in accordance with Table 1. Moisture contents shall be as per zonal requirements in accordance with **4.4**.

15.4 Plywood

Boiling water proof (BWP) grade preservative treated plywood shall be used in accordance with accepted standards [C-3A(13)]. Introduction of a plywood gusset simplifies the jointing and in addition provides rigidity to the joint. Preservation of plywood and other panel products shall be done in accordance with good practice [C-3A(15)].

15.5 Some design data on the lateral load bearing strength of common wire nails in plywood-to-wood joints are presented for timber species, Sal and Chir in Table 22, for guidance in design.

16 STRUCTURAL SANDWICHES

16.1 General

Sandwich constructions are composites of different materials including wood based materials formed by bonding two thin facings of high strength material to a light weight core which provides a combination of desirable properties that are not attainable with the individual constituent materials (*see* Fig. 18). The thin facings are usually of strong dense material since that are the principal load carrying members of the construction. The core should be stiff enough to ensure the faces remain at the correct distance apart. The sandwiches used as structural elements in building construction shall be adequately designed for their intended services and shall be fabricated only where there are adequate facilities for gluing or otherwise bonding cores to facings to ensure a strong and durable product. The entire assembly provides a structural element of high strength and stiffness in proportion to its mass.

Non-structural advantages can also be derived by proper selection of facing and core material, for example, an impermeable facings can be used to serve as a moisture barrier for walls and roof panels and core may also be selected to provide thermal and/or acoustic insulation, fire resistance, etc, besides the dimensional stability.

16.2 Cores

Sandwich cores shall be of such characteristics as to give to the required lateral support to the stressed facings to sustain or transmit the assumed loads or stresses. Core generally carries shearing loads and to support the thin facings due to compressive loads. Core shall maintain the strength and durability under the conditions of service for which their use is recommended. A material with low *E* and small shear modulus may be suitable.

16.3 Facings

Facings shall have sufficient strength and rigidity to resist stresses that may come upon them when fabricated into a sandwich construction. They shall be thick enough to carry compressive and tensile stresses and to resist puncture or denting that may be expected in normal usages.

16.4 Designing

Structural designing may be comparable to the design of I-beams, the facings of the sandwich represent the flanges of the I-beam and the sandwich core I-beam web.

NOTES

1 Plywood shall be of shuttering grade as per the accepted standard [C-3A(16)].

2 Subject to satisfying all the design requirements in structures:

a) For denser species, timber thickness of 30 mm may be used by means of a plywood of 9 mm thickness for all practical purposes. For species like Chir, plywood thickness of 12 mm may be used with 30 mm or 40 mm timber thickness.

b) Regarding aligning the veneers of plywood plate; nail strength data may be used as design function irrespective of alignment of face veneer to overcome practical difficulties.

c) While prebore is essential to drive nail in structural timber as per the good pratice [C-3A(7)], plywood plates need not be prebored for nailing.

16.5 Tests

Panels of sandwich construction shall be subject to testing in accordance with accepted standards [C-3A(17)]. Tests shall include, as applicable, one or more of the following:

a) Flexural strength/stiffness;

b) Edge-wise compressions;

c) Flat-wise compression;

d) Shear in flat-wise plane;

e) Flat-wise tensions;

f) Flexural creep (creep behaviour of adhesive);

g) Cantilever vibrations (dynamic property); and

h) Weathering for dimensional stability.

17 LAMELLA ROOFING

17.1 General

The lamella roofing offers an excellent architectural edifice in timber, amenable to prefabrication, light weight structure with high central clearance. It is essentially an arched structure formed by a system of intersecting skewed arches built-up of relatively short timber planks of uniform length and cross section. Roof is designed as a two hinged arch with a depth equal to the depth of an individual lamella and width equal to the span of the building. The curved lamellas (planks) are bevelled and bored at the ends and bolted together at an angle, forming a network (grid) pattern of mutually braced and stiffened members (*see* Fig. 19 and Fig. 20).

The design shall be based on the balanced or unbalanced assumed load distribution used for roof arches. Effect of deformation or slip of joints under load on the induced stresses shall be considered in design. Thrust components in both transverse and longitudinal directions of the building due to skewness of the lamella arch shall be adequately resisted. Thrust at lamella joints shall be resisted by the moment of inertia in the continuous lamella and roof sheathing (decking) of lamella roofing. The interaction of arches in two directions adds to the strength and stability against horizontal forces. For design calculations several assumption tested and observed derivations, long-duration loading factors, seasoning advantages and effects of defects should be taken into account.

17.2 Lamellas

Planking shall be of a grade of timber that is adequate in strength and stiffness to sustain the assumed loads, forces, thrust and bending moments generated in lamella roofing. Lamella planks shall be seasoned to a moisture content approximating that they will attain in service. Lamella joints shall be proportioned so that allowable stresses at bearings of the non-continuous lamellas on the continuous lamellas or bearings under the head or washer of bolts are not exceeded.

17.2.1 *Design Sequence and Methods*

A lamella roof is essentially an arch (segmental, parabolic or elliptical) formed by a system of intersecting skewed arches, built up of relatively short members of small dimensional planks called ‘lamellas’. The arch is designed as a two hinged arch with a depth equal to the depth of the individual lamella and a width equal to the span of the building of certain length. For design purposes, a unit length of the given span forming a single arch is considered loaded with the given loads. For the particular arch, curvature offers resultant outward suction on the roof to be less than its self weight to facilitate design and construction for economy (this is possible only when the semi-angle of arch is less than 42°).

Some design assumptions that should be considered include:

a) Self weight of timber components (in particular species), namely lamella planks, roof boarding, wall plates, etc is assumed for the particular timber section;

b) Imposed loads as per Part C ‘Structural Design, Section 1 Loads and Load Effects’ of this NBCS for curved roofs where slope at springing point is greater than 10°. Take the reduced worked out values of imposed loads for actual design for timber components as per this Subsection;

c) Wind load is taken as per Part C ‘Structural Design, Section 1 Loads and Load Effects’ of this NBCS for structures with large openings, that is, openings larger than 20 percent of wall area (or as the case may be);

d) Stresses developed in curved lamella planks should not exceed the allowable safe stresses of timber species used;

e) Range of various sizes of timber planks for lamellas shall be as under:

   1) *Length* — 1.0 m to 2.5 m;

   2) *Section*:

      i) *Thickness* — 25 mm to 50 mm; and

      ii) *Width of uncurved plank* — 100 mm to 250 mm.

f) Limitations to be observed for spacing of lamellas over wall plate (or bressummer):

   1) i) For skew angle of 21° (diamond angle 42°);
      ii) For 2.5 m length of plank, spacing shall be 870 mm maximum; and
      iii) For 1.0 m length, spacing shall be 360 mm maximum.

   2) i) For skew angle of 19° (diamond angle 38°);
      ii) For 2.5m length of plank, spacing shall be 800 mm maximum; and
      iii) For 1.0 m length of plank, spacing shall be 320 mm maximum.

g) Value of horizontal thrust, resultant thrust and maximum bending moment, are taken on per metre length of structure in case of transverse direction of arch;

h) Bending moment may be suitably reduced, if so desired by the designer, by applying stability factor if the ratio of the length of structure to the curved length of arch so warrants (as this ratio increases, the stability of the structure decreases);

j) The thrust in the skewed direction of arch, within one spacing of lamellas is shared by two lamella-lines in skewed direction; and

k) More than one bolt (MS) shall be used for nodal joint. For design check of bolt against tension, half the value of thrust in skewed direction will be considered for calculations purposes in light of (j) {in case of stiff roof covering material [that is, corrugated galvanized iron (CGI) sheet, close boarding, etc] all lamella planks will be held jointly behaving as a monolithic unit to a large extent and the actual stresses developed in bolt will be reduced resulting in lesser actual tension in bolts than the calculated design value}.

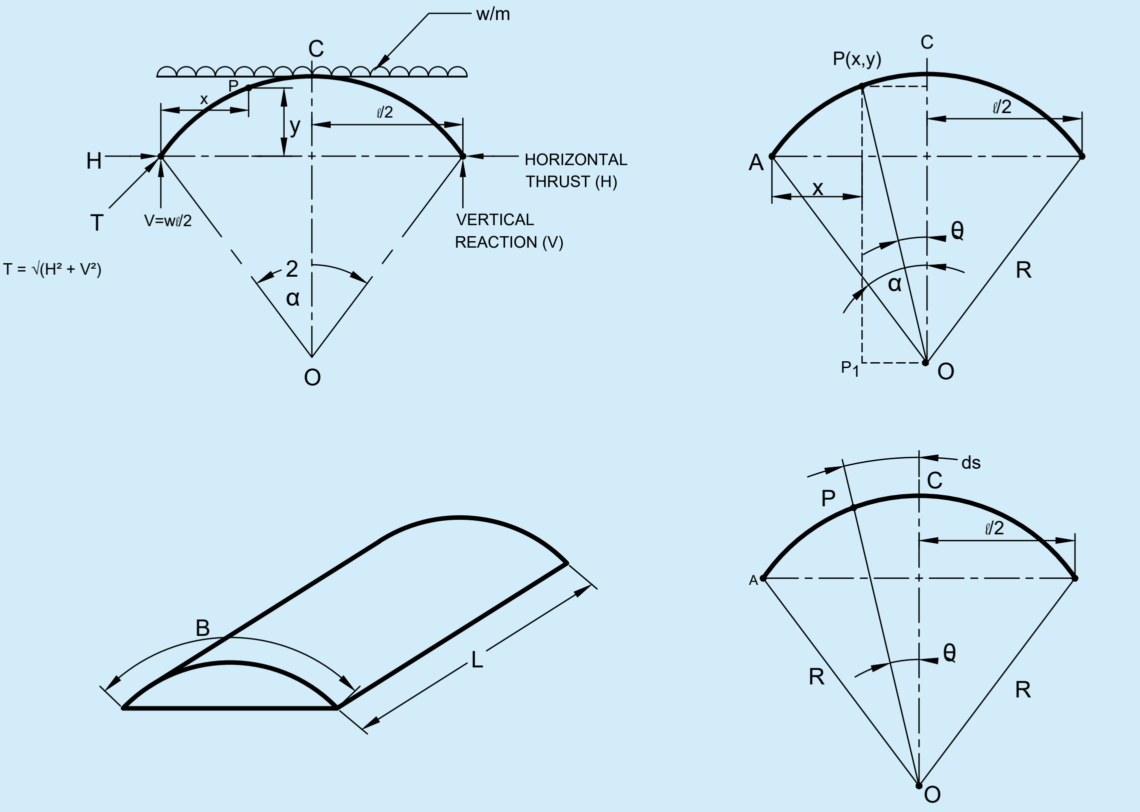
LOAD REACTION DIAGRAM

FIG. 19 TYPICAL ARRANGEMENT OF LAMELLA ROOFING



NOTES

1 When the ratio of length of the structure (*L*) to the circumference of the arch (*B*) increases, stability of the structure decreases. The roof should be designed as:

a) short roof (say, *L/B* = 1), or

b) long roof (say, *L/B* = 1.5).

Shorter roofs have an advantage over long roofs for economical design. However, there is no such advantage beyond *L/B* of 4.

2 Due to stiff roof covering material, stiffness is induced in an arch, which results in safer design.

FIG. 20 STABILITY OF LAMELLA ARCH ROOF

17.2.1.1 *Horizontal thrust*

Any of the known methods for solving a statically indeterminate structure is used to evaluate horizontal thrust, bending moment, etc, to which a segmental arch will be subjected under the given condition of loadings. For 60° segmental arch, the radius of an arch will be equal to the span of the arch. Horizontal thrust can be calculated by the following two methods:

a) *Method* 1

Horizontal thrust (H_B) per length of one bay (that is, distance between 'tie-rod spacing' or 'column centres'):

$$H_B = (DL + IL) \times \left[\frac{l^2 + {s_t}^2}{8r}\right]$$

where

H_B = horizontal thrust, in N;

DL = dead load, in N;

IL = imposed load, in N;

l = span of arch, in m;

s_t = tie-rod spacing, in m; and

r = rise of roof arch, in m.

b) *Method* 2

Horizontal thrust (H_1) per metre length of structure (in N):

$$H_1 = C \times w \times R$$

where

C = coefficient varying with the angle of arch and radius of arch;

w = equivalent distributed load per metre of span (in N/m); and

R = radius of circular arch (in m).

Horizontal thrust (H_1) is evaluated as:

$$H_1 = \frac{\int \mu y ds}{\int y^2 ds}$$

where

H_1 = horizontal thrust (per metre length of structure), in N;

μ = bending moment at any point 'P' distance 'x' metre from one end of springing point of arch and for vertical loads only (consider arch as a beam simply supported carrying the same load);

y = height of point 'P' above springing line of arch;

θ = angle which the point 'P' makes at the centre of arch with the vertical; and

ds = $Rd\theta$.

Now solution for numerator:

$$\mu = \frac{wl}{2}x - wx\frac{x}{2}$$

$$= \frac{wx}{2}\,(l - x)$$

where

$$x = \frac{l}{2} - R\sin\theta$$

$$x = \frac{R}{2} - R\sin\theta$$

$$x = R\left(\frac{1}{2} - \sin\theta\right)$$

and $y = R\cos\theta - R\cos\alpha$

$y = R(\cos\theta - \cos\alpha)$

and $ds = Rd\theta$

Substitute the values in expression:

$$\int \mu y ds = \int \frac{wx(l-x)}{2} R(cos\,\theta - cos\,\alpha)Rd\theta$$

Solve for limits of θ from $-\alpha$ to $+\alpha$ = $\int_0^{\alpha} wR^4(\frac{1}{4} - sin^2\,\theta)(cos\,\theta - cos\,\alpha)d\theta$

Again for denominator;

$$\int y^2\,ds = \int_{-\alpha}^{+\alpha} R^2(\cos\theta - \cos\alpha)^2 Rd\theta$$

$$= 2R^3 \int_0^{\alpha} (\cos\theta - \cos\alpha)^2\,d\theta$$

Therefore, $H_1 = \frac{\int \mu y ds}{\int y^2 ds}$

$$= \frac{wR^4 \int_0^{\alpha} \left[\frac{1}{4} - \sin^2\theta\right](\cos\theta - \cos\alpha)\,d\theta}{2R^3 \int_0^{\alpha}(\cos\theta - \cos\alpha)^2\,d\theta}$$

On simplification of the above equation for a particular arch, $\alpha = 30°$, $R = l$ (α in radian = 0.5 approx),
$\sin\alpha = 1/2$
$\cos\alpha = \sqrt{3}/2$

$H_1 = 0.923\,wR$

Vertical reaction, $V_1 = \frac{Total\ load \times span}{2}$ at each end of arch due to dead and live loads per metre length (curved strip) of arch roofing.

17.2.1.2 *Resultant thrust*, T_1

Due to horizontal thrust and the vertical reaction, resultant transverse thrust, in kg per metre length on the arch can be worked out:

$$T_1 = \sqrt{{H_1}^2 - {V_1}^2}$$

17.2.1.3 *Maximum bending moment*

Bending moment at any point 'P' on arch making an angle of θ with the vertical line OC is, $BM = \mu - (H \times y)$
$= \frac{wR^2}{2}\left(\frac{1}{4} - \sin^2\theta\right) - 0.923wR^2\left(\cos\theta - \frac{\sqrt{3}}{2}\right)$

Differentiating the above expression for BM, we get

$$\frac{dM}{d\theta} = (-\sin\theta\cos\theta + 0.923\sin\theta)wR^2$$

It is well known that $\frac{dM}{d\theta}$ = shear force

This shear is zero when BM is maximum, that is:

either θ = zero

or $\cos\theta = 0.923$

Therefore, $\theta = \cos^{-1}0.923 = 22.6°$

Substituting these values in the above equation of bending moment, we get maximum BM, that is, the maximum BM occurs at:

a) crown of arch; and

b) at 22.6° from the central line OC.

Thus when $\theta = 0$

$$BM = \frac{wR^2}{2} \times \frac{1}{4} - 0.923wR^2\left(1 - \frac{\sqrt{3}}{2}\right)$$

$$= wR^2(0.125 - 0.12368)$$

$$= 0.001\ 32wR^2$$

When $\theta = 22.6°$, $\sin\theta = 0.384$

$$BM = \frac{wR^2}{2}\left(\frac{1}{4} - 0.384\right)^2 - 0.923wR^2(0.923 - 0.866)$$

$$= wR^2(0.125 - 0.073\ 728) - 0.923 \times 0.057wR^2$$

$$= -0.001\ 339wR^2 \text{ or say } -0.001\ 34wR^2$$

The arch has to be designed for the greater of the two values (subject to the longitudinal stiffness coefficient on the basis of ratio *L*/*B* of length of the structure to the circumference of the arch) for economical design.

NOTE — Value of horizontal thrust, H_1, resultant thrust, T_1 and bending moment, M_1 shall be for 1 m length of building.

17.2.1.4 *Spacing of lamellas*

Lengthwise spacing of lamellas depends upon the angle of skew lamellas and the length of the planks used for lamellas (As a general guidance it may be stated that the angle enclosed between the intersecting skewed arches should not exceed 45°. An angle between 38° and 40° is always preferred).

17.2.1.5 *Design of lamella sizes*

Net section of each of lamellas is assumed in curved profile conforming to the curvature of the roof surface.

Maximum BM = M_s over 600 mm spacing of lamella in the direction of skew angle, for example:

$$= \frac{0.6M_1 \times 10}{\cos 19°} \text{ Nm}$$

where

M_1 = maximum bending moment per metre length of structure in transverse direction.

And maximum thrust *N* (in Newton) on this strip of 600 mm in skewed direction is:

$$N = \frac{0.6T_1}{\cos 19°} \times \frac{1}{2}$$

(as the force T_1 is shared by two lines of lamellas)

where

N = maximum thrust on 600 mm strip in skewed direction; and

T_1 = resultant thrust in transverse direction (in N) per metre length of structure.

Now total compressive and flexural stresses should not exceed the allowable safe stress of timber species used for lamella plank. For fulfilling this condition the following equation should be checked:

$$\frac{N/A}{f_{c\,\mathrm{II}}} + \frac{M_s/Z}{f_t} \leq 1$$

where

N = maximum thrust in skewed direction on strip of 600 mm (in N) corresponding to the maximum bending moment;

A = cross-sectional area of lamella plank, in mm^2;

Z = section modulus of lamella plank, in mm^3;

$f_{c\,\mathrm{II}}$ = safe compression strength of timber fibre parallel to grain, N/mm^2;

M_s = bending moment over 600 mm strip of arch in skewed direction, Nmm;

f_t = safe tensile strength of timber parallel to grain, N/mm^2; and

NOTE — In case the lamella plank is under stressed, the minimum section for practical reasons shall be 25 mm × 100 mm subject to satisfying minimum edge and intermediate distances for accommodating bolts at nodal joints.

17.2.1.6 *Design of bolts for nodal joint*

To avoid any possibility of hinge action with the use of bolts, it is imperative to adopt two or more bolts of smaller diameter and adequately spaced in accordance with the good practice [6-3A(9)].

Assume diameter of bolt 'd' in mm, and length of bolt in one plank 't' mm, that is, thickness of middle lamella plank.

Area of contact of bolt with timber plank = $d \times t$ mm^2

a) *Check against crushing of timber at contact point of bolt* — For the bolt to transmit load without crushing the timber fibres, the following condition shall be satisfied:

$$t \times d \times \text{compressive stress perpendicular to grain for the timber species} > P$$

where

P = total load to be transmitted through bolt, in N.

b) *Check against tension in bolt* — Arrangement of bolts at the junction of lamellas result in pure tension in bolt as bolt line is at right angle to the outer two lamellas:

Therefore, $Z_t = N \times \cot 2\phi$

where

Z_t = tension in bolt, in N;

N = normal thrust corresponding to maximum moment M_s (in N); and

$= \frac{T_1}{\cos} \times \frac{1}{2}$

T_1 = resultant thrust in transverse direction (in N) per metre length of structure.

Therefore;

Area of bolt (A_t) × tensile stress of steel (F_t) $\geq Z_t$

Area of bolt required for safe design = Z_t/F_t

Select the diameter to engage at least two bolts.

(Required area of bolt is the effective area after considering reduction of area at the threaded end, which is generally 17 percent of the actual bolt diameter).

17.2.1.7 *Design of steel washer at joints*

Area of steel plate = A_t mm^2

Stress perpendicular to grain of wood at the point of contact with steel plate washer = Z_t/A_t N/mm^2

If $Z_t/A_t \leq$ compressive stress perpendicular to grain of the species of timber used, the assumed section is safe.

17.3 Construction

Design and construction of lamella roofs in India assumes the roof surfaces to be cylindrical with every individual lamella an elliptic segment of an elliptical arch of constant curved length but of different curvature. Lamella construction is thus more of an art than science as there is no analytical method available for true generation of schedule of cutting lengths and curvature of curved members forming the lamella grid. Dependence of an engineer on the practical ingenuity of master carpenter is almost final. All the lamella joints shall be accurately cut and fitted to give full bearing without excessive deformation or slip. Bolts at lamella splices shall be adequate to hold the members in their proper position and shall not be over tightened to cause bending of the lamellas or mashing of wood under the bolt heads. Connection of lamellas to the end arches shall be adequate to transmit the thrust or any other force. Sufficient false work or sliding jig shall be provided for the support of lamella roof during actual construction/erection. To avoid excessive deformation in a lamella system, all joints should be carefully fitted and well tightened.

18 NAIL AND SCREW HOLDING POWER OF TIMBER

18.1 General

One of the most common ways of joining timber pieces to one another is by means of common wire nails and wood screws. Timber is used for structural and non-structural purposes in form of scantlings, rafters, joists, boarding, crating and packing cases, etc, needing suitable methods of joining them. Nevertheless, it is the timber which holds the nails or screws and as such pulling of the nails/screws is the chief factor which come into play predominantly. In structural nailed joints, nails are essentially loaded laterally, the design data for which is already available in good practice [C-3A(7)]. Data on holding power of nails/screws in different species is also useful for common commercial purposes. The resistance of mechanical fastenings is a function of the specific gravity of wood, direction of penetration with respect to the grain direction, depth of penetration and the diameter of fastener assuming that the spacing of fasteners should be adequate to preclude splitting of wood.

18.2 Nails

Nails are probably the most common and familiar fastener. They are of many types and sizes in accordance with the accepted standard [C-3A(18)]. In general nails give stronger joints when driven into the side grain of wood than into the end grain. Nails perform best when loaded laterally as compared to axial withdrawal so the nailed joints should be designed for lateral nail bearing in structural design. Information on withdrawal resistance of nails is available and joints may be designed for that kind of loading as and when necessary.

18.3 Screw

Next to the hammer driven nails, the wood screw may be the most commonly used fastener. Wood screws are seldom used in structural work because of their primary advantage is in withdrawal resistance for example for fixing of ceiling boards to joists, purlin cleats, besides the door hinges, etc. They are of considerable structural importance in fixture design and manufacture. Wood screws are generally finished in a variety of head shapes and manufactured in various lengths for different screw diameters or gauges in accordance with the accepted standards [C-3A(19)].

The withdrawal resistance of wood screws is a function of screw diameter, length of engagement of the threaded portion into the member, and the specific gravity of the species of wood. Withdrawal load capacity of wood screws are available for some species and joints may be designed accordingly. End grain load on wood screws are unreliable and wood screws shall not be used for that purpose.

18.4 Nail and screw holding power is one of the very important properties of timber which governs its utilization in diverse industrial and engineering fields. This has been evaluated by experimental method followed for evaluation of such properties as per normal procedure given in the accepted standards [C-3A(20)], using:

a) *Specimen* — of size 150 mm × 50 mm × 50 mm;

b) *Nail* — diamond pointed wire nail of 50 mm length and 2.50 mm shank diameter;

c) *Screw* — galvanized gimlet pointed, No. 8; and

d) *Conditions* — penetration 25 mm.

While nails were driven by a hand hammer, screws were driven by a screw driver in a 2.5 mm diameter prebore on radial, tangential and end faces.

Composite nail and screw holding power of some Indian timbers, evaluated as above, is presented in Table 23 for guidance in design.

Table 23 Composite Nail and Screw Holding Power of Some Indian Timbers

19 PROTECTION AGAINST TERMITE ATTACK IN BUILDINGS

19.1 Two groups of organisms which affect the mechanical and aesthetic properties of wood in houses are fungi and insects. The most important wood destroying insects belong to termites and beetles. Of about 250 species of wood destroying termites recorded in India, not more than a dozen species attack building causing about 90 percent of the damage to timber and other cellulosic materials. Subterranean termites are the most destructive of the insects that infest wood in houses justifying prevention measures to be incorporated in the design and construction of buildings.

19.1.1 Control measures consist in isolating or sealing off the building from termites by chemical and non-chemical construction techniques. It is recognized that 95 percent damage is due to internal travel of the termites from ground upwards rather than external entry through entrance thus calling upon for appropriate control measures in accordance with good practices [C-3A(21)].

19.2 Chemical Methods

Termites live in soil in large colonies and damage the wooden structure in the buildings by eating up the wood or building nests in the wood. Poisoning the soil under and around the building is a normal recommended practice. Spraying of chemical solution in the trenches of foundations in and around walls, areas under floors before and after filling of earth, etc. In already constructed building the treatment can be given by digging trenches all around the building and then giving a liberal dose of chemicals and then closing the trenches.

19.3 Wood Preservatives

Natural resistance against organisms of quite a few wood species provides durability of timber without special protection measure. It is a property of heartwood while sapwood is normally always susceptible to attack by organisms. Preservatives should be well applied with sufficient penetration into timber. For engineers, architects and builders, the following are prime considerations for choice of preservatives:

a) Inflammability of treated timber is not increased and mechanical properties are not decreased;

b) Compatibility with the glue in laminated wood, plywood and board material;

c) Water repellent effect is preferred;

d) Possible suitability for priming coat;

e) Possibility of painting and other finishes;

f) Non-corrosive nature in case of metal fasteners; and

g) Influence on plastics, rubber, tiles and concrete.

19.4 Constructional Method

Protection against potential problem of termite attack can simply be carried out by ordinary good construction which prevents a colony from gaining access by:

a) periodic visual observations on termite galleries to be broken off;

b) specially formed and properly installed metal shield at plinth level; and

c) continuous floor slabs, apron floors and termite grooves on periphery of buildings.

20 CROSS-LAMINATED TIMBER (CLT)

Cross-laminated timber (CLT) is an engineered wood product used as a structural component in mass timber construction. CLT panels shall consist of not less than three layers of solid-sawn lumber or structural composite lumber, with adjacent layers cross-oriented and bonded with structural adhesives to form a solid wood element.

20.1 General Requirements

20.1.1 *Material Specifications*

CLT panels shall be manufactured to meet stringent performance criteria for mechanical properties, including load-bearing capacity, dimensional tolerances, and adhesive bond durability to ensure structural reliability. Panels should also demonstrate resistance to delamination and other essential physical properties through rigorous testing to validate long-term performance under various environmental conditions.

The timber used for CLT production shall be kiln-dried to a moisture content of 12 percent ± 2 percent, ensuring stability and resistance to deformation.

20.1.2 *Dimensions*

CLT panels shall have a minimum thickness of 50 mm, with thicknesses ranging up to 500 mm for structural applications. The typical panel dimensions for commercial use may be up to 18 000 mm in length and 3 000 mm in width.

The number of layers shall be odd (for example, 3, 5, 7), with layer thicknesses adjusted according to structural requirements.

20.2 Physical Properties

20.2.1 *Delamination Resistance*

Delamination testing shall be conducted to ensure that total delamination ($\mathit{Delam}_{\mathrm{tot}}$) shall not exceed 10 percent, and maximum delamination ($\mathit{Delam}_{\mathrm{max}}$) shall not exceed 40 percent, ensuring durability and structural integrity.

Results from studies indicate that CLT made from plantation-grown hardwoods such as Rubberwood, *Melia dubia* (*Malabar Neem*), and Eucalyptus meets these requirements, with delamination values comparable to Radiata pine, a commonly used species in CLT production.

20.2.2 *Water Absorption and Swelling Properties*

CLT panels shall be evaluated for water absorption (WA), thickness swelling (TS), and volumetric swelling (VS) using the water soaking method. These parameters shall be assessed to ensure that the panels meet acceptable limits for moisture-induced dimensional changes, maintaining stability under varying environmental conditions.

Reference to results from studies (Table 24 and Table 25) shows that hardwood species demonstrate comparable performance to Radiata pine, indicating their suitability for structural applications.

For detailed information, a reference may be made to *A Hybrid Approach to Green Building Construction Using Mass Timber February* 2024, DOI: 10.58532/V3BICE3P8CH2 by Ram Kumar V R and Amitava Sil.

NOTE — Values in the parentheses indicate standard deviation.

20.2.3 *Density*

The density of CLT panels shall be determined according to the timber species and adhesive used. The density of CLT panels shall range from 5 500 kg/m³ to 8 500 kg/m³, depending on the species (for example, Rubberwood, Eucalyptus). Table 26 provides the density values for different species used in CLT production.

Table 26 Density of CLT Panels

(*Clause* 20.2.3)

Sl No. (1)	**Species** (2)	**Density of Wood (at 12 Percent Moisture Content)** kg/m^3 (3)	**Density of CLT** kg/m^3 (4)

vii)	MEM	–	6 400 (0.03)
viii)	MSM	–	5 500 (0.02)
ix)	SMS	–	6 700 (0.01)

NOTE — Values in the parentheses indicate standard deviation.

20.3 Mechanical Properties

20.3.1 *Bending, Compression, and Shear Strength*

Mechanical testing shall include four-point bending tests, compression parallel to grain tests and block shear tests. The results shall comply with the minimum strength requirements for structural applications as specified in Part C 'Structural Design, Section 1 Loads and Load Effects' of this NBCS.

Table 27 and Table 28 present the mechanical properties of homogeneous and hybrid CLT panels, showing adequate performance for structural uses. Rubberwood CLT exhibited higher mechanical properties than hybrid configurations in some tests.

20.3.2 *Impact of Adhesive Type on Mechanical Performance*

The choice of adhesive (for example, phenol resorcinol formaldehyde, PUR) shall be considered, as it affects the bonding strength and durability. Mechanical properties of CLT bonded with different adhesives, indicating that PRF-bonded panels have superior performance.

Table 27 Mechanical Properties of Homogeneous CLT Panels

iv)	MSM	6 328 (652.8)	45.5 (4.3)	24.2 (3.1)	5.3 (0.5)

NOTE — Values in the parentheses indicate standard deviation.

20.4 Fire Safety Requirements

20.4.1 *Fire Resistance Ratings*

CLT panels should have a fire-resistance rating in accordance with Part F 'Fire and Life Safety' of this NBCS. This shall be achieved through inherent fire resistance, encapsulation with materials like gypsum board (minimum thickness 13 mm), or a combination of methods.

The charring rate of CLT shall be considered in fire design calculations, with a recommended charring rate of 0.65 mm/min for calculating the load-bearing capacity during fire exposure.

20.4.2 *Protection of Connections*

Steel connectors and other metal components shall be protected with fire-resistant coatings or encased in non-combustible materials to ensure structural integrity during a fire.

20.5 Durability and Biological Resistance

20.5.1 *Preservative Treatments*

CLT panels shall be treated with preservatives like bifenthrin or copper chrome borate to enhance resistance to biological degradation. Testing has shown that preservative-treated CLT has improved resistance to termite and fungal attacks compared to untreated samples (*see* Table 29 for termite degradation results).

Table 29 Degradation of Samples due to Termite Attack

(*Clause* 20.5.1)

Sl No. (1)	**Sample** (2)	**Average Degradation** percent (3)	**Duration of Exposure** months (4)
i)	Control solid wood	100	6
ii)	Control CLT	100	9
iii)	Calcium channel blockers (CCB) treated CLT	60	36
iv)	Bifenthrin treated CLT	0	36

20.5.2 *Performance Under Biological Exposure*

Durability testing shall include assessments for resistance to termites, white rot and brown rot fungi. Untreated rubberwood is highly susceptible to biological degradation, while treated samples showed minimal degradation after prolonged exposure.

20.5.3 *Effect of Preservatives on Mechanical Properties*

The use of preservatives should not adversely affect the mechanical properties of CLT. Block shear strength tests indicate that treated panels retain comparable mechanical performance to untreated panels.

20.6 Handling, Storage and Installation

20.6.1 *Moisture Protection*

During construction, CLT panels shall be protected from moisture exposure. Panels should be stored in a dry environment and water infiltration during transportation and installation shall be minimized.

21 MASS TIMBER

Structural elements primarily composed of solid, built-up, panelized, or engineered wood products are categorized as products which include, but are not limited to, cross-laminated timber (CLT), glued-laminated timber (glulam), and laminated veneer lumber (LVL). It consists of multiple layers of wood, mechanically or adhesively bonded together to create large, strong and stable components suitable for load-bearing and non-load-bearing uses in construction. Mass timber elements can be used for structural framing, walls, floors, roofs and columns. It applies to the construction of residential, commercial, and public buildings where structural elements, including floors, walls, roofs and columns, are made from engineered wood products like cross-laminated timber (CLT), glued-laminated timber (glulam) and other solid or panellised wood products.

These load-bearing and non-load-bearing products include:

a) Cross-laminated timber (CLT);

b) Glued-laminated timber (Glulam);

c) Nail-laminated timber (NLT); and

d) Laminated veneer lumber (LVL).

21.1 Design and Structural Integrity

21.1.1 *Structural Design Requirements*

a) *Load-bearing capacity* — Mass timber elements shall be designed to carry the vertical and lateral loads imposed on the building in compliance with Part C ‘Structural Design, Section 1 Loads and Load Effects’ of this NBCS. The design shall account for dead loads, live loads, wind loads, seismic loads and other imposed loads;

b) *Cross-sectional dimensions* — The minimum cross-sectional dimensions for mass timber elements (for example, columns, beams, floor slabs) shall be specified based on building height, function and occupancy. For example, CLT panels used for floor slabs should meet a minimum thickness of 100 mm, depending on the structural requirements; and

c) *Deflection limits* — The design of mass timber structures shall ensure that the deflection under service load conditions remains within acceptable limits as defined in this Part of this NBCS.

21.1.2 *Hybrid Systems*

Where mass timber is used in conjunction with steel or concrete, the design should ensure that load paths are continuous and that materials are compatible. Load transfer mechanisms shall be adequately designed to prevent failure at the connection points between materials.

21.1.3 *Seismic Performance*

Mass timber buildings located in seismic zones should be designed to accommodate lateral loads and displacements as per Part C ‘Structural Design, Section 1 Loads and Load Effects’ of this NBCS. Timber's flexibility can offer good seismic performance, but connections and structural integrity should be robustly designed to prevent failure.

21.2 Fire and Life Safety

It should be ensured in accordance with Part F ‘Fire and Life Safety’ of this NBCS.

21.2.1 *Protection of Connections*

All steel connectors, bolts and fasteners used in mass timber construction shall be protected with fire-resistant coatings or enclosed within non-combustible materials to prevent failure during fire exposure.

21.3 Minimum Dimensions and Thickness of Mass Timber Elements

21.3.1 *Columns and Beams*

Mass timber columns and beams shall be designed to meet the structural load requirements with a minimum cross-sectional dimension of 200 mm for columns and 150 mm for beams, depending on the span and load requirements.

21.3.2 *Floor and Roof Panels*

CLT panels used for floor and roof assemblies should meet a minimum thickness of 100 mm for floor systems and 85 mm for roof systems to achieve the required fire and structural performance.

21.3.3 *Wall Panels*

CLT or NLT wall panels shall meet a minimum thickness of 125 mm to ensure fire resistance and structural stability under lateral and vertical loads.

21.4 Construction Practices

21.4.1 *Handling and Installation of Mass Timber Elements*

During construction, care should be taken to protect mass timber elements from moisture. Elements shall be stored in dry conditions and protected from water exposure during construction to prevent damage and degradation.

21.4.2 *Assembly and Connections*

Connections between mass timber elements (for example, floor-to-wall, beam-to-column) should be engineered to handle both static and dynamic loads. These connections shall be made using metal connectors, dowels, or bolts designed to prevent movement and ensure continuous load transfer. Special attention should be paid to fire protection at these connection points.

21.4.3 *Fire Sealing of Penetrations*

Any penetrations for services (for example, plumbing, electrical) through mass timber elements shall be sealed with approved fire-rated materials to maintain the integrity of the fire-rated assembly.

21.5 Sustainability and Environmental Benefits

21.5.1 *Environmental Performance*

Mass timber is recognized for its carbon sequestration properties, where wood captures and stores carbon dioxide. Buildings made from mass timber reduce the overall carbon footprint of the construction process compared to traditional materials like steel and concrete.

21.5.2 *Energy Efficiency*

Mass timber inherent thermal insulation properties help to regulate indoor temperatures, thereby reducing energy consumption for heating and cooling. The thermal resistance of wood should be considered in the building envelope design, allowing for thinner wall assemblies with better insulation compared to conventional materials.

22 LIFE CYCLE ASSESSMENT (LCA) OF TIMBER FOR USE IN BUILDINGS

22.1 Timber used in building structures and elements shall undergo a comprehensive life cycle assessment (LCA) to evaluate its environmental impacts across its entire lifecycle, from raw material extraction to disposal or recycling. LCA provides valuable insights into the sustainability of timber and its environmental footprint in building applications. The assessment shall cover the following stages:

a) *Production and Construction* — This stage evaluates the energy and resources required for the extraction, transportation and processing of raw timber into building materials. It also includes the energy consumption and waste generated during the construction process, as well as the transportation of materials to the construction site.

b) *Use Stage* — The use stage assesses the environmental impacts of timber during the building's operational lifespan. This includes maintenance, repairs and potential replacement of timber components, considering the durability, performance and long-term sustainability of the material.

c) *End-of-Life* — At the end of the building's useful life, the timber structure may undergo demolition, with the materials being processed for waste management, recycling, or reuse. This stage assesses the environmental effects of these processes and the potential for timber materials to be repurposed.

d) *Externalized Impacts beyond the System Boundary* — The incidental effects of recycling, reusing and recovering energy, water, or materials beyond the system boundaries of the LCA study are included in this stage. These externalized impacts consider how recycled timber or materials might contribute to environmental benefits outside the building's lifecycle.

22.2 Environmental Impact Categories

The LCA may be used to assess the environmental impact of timber buildings in several categories, which encompass emissions and pollutants generated throughout the lifecycle. These categories include:

a) *Global Warming Potential* — The contribution of greenhouse gas emissions to climate change;

b) *Acidification Potential* — The potential for acidic compounds to form in the environment, affecting ecosystems and infrastructure;

c) *Eutrophication Potential* — The impact of nutrient loading on water bodies, potentially causing excessive algal growth;

d) *Ozone Depletion Potential* — The impact of substances that contribute to the depletion of the ozone layer; and

e) *Smog Formation Potential* — The potential for air pollution to contribute to the formation of ground-level ozone and smog.

All relevant material and process quantities shall be included in the LCA inventory and their impacts shall be calculated using recognized tools and methodologies.

22.3 Requirements for Life Cycle Assessment

In the context of building with timber, LCA may be required for the following purposes:

a) *Decision-Making Support* — Providing building owners and stakeholders with data on the environmental and sustainability aspects of timber, aiding informed decision-making;

b) *Design Evaluation* — Offering insights into material selection and environmental performance across different design possibilities;

c) *Product Comparison* — Demonstrating the environmental advantages of timber in comparison to alternative building materials;

d) *Environmental Benefit Evaluation* — Helping assess the ecological benefits of innovative timber products or policies; and

e) *Performance Benchmarking* — Comparing the environmental performance of timber buildings against established benchmarks and sustainability goals.

22.4 Methodology for Conducting LCA

The LCA of timber buildings may be conducted iteratively, with increasing detail as the design or construction phases progress. The process should follow these steps:

a) Establish the purpose and scope of the LCA, focusing on the objectives of evaluating timber's environmental impact;

b) Gather data on the timber materials, including their types, quantities, lifespans and lifecycle stages. Special attention should be given to materials used in the production and use stages;

c) Using LCA tools (for example, SimaPro, MATLAB), assess the environmental impacts of timber buildings. The evaluation shall include biogenic carbon considerations, as timber stores carbon from the atmosphere, contributing to carbon sequestration during its lifecycle;

d) Interpret the LCA results by categorizing environmental impacts by building component, material type, and lifecycle stage. Identify key contributors to the building's overall environmental footprint and visualize the outcomes; and

e) Document all findings, including assumptions, methodology and conclusions and present the results in reports for stakeholders. The results shall guide sustainable construction practices and decision-making in timber building projects.

22.5 Reporting

The results of the LCA should be documented, including all assumptions, methodologies and conclusions. Reports should be prepared in accordance with relevant standards and may be used to guide sustainable building practices and decision-making in construction.

ANNEX A

(*Clause* 4.1)

MECHANICAL PROPERTIES OF FOREIGN TIMBER SPECIES

A-1 The Table 30 below specifies the mechanical properties of selected foreign timber species, indicating their density, modulus of elasticity, permissible stresses, and preservative characteristics. This information is intended to serve as a reference for designers and engineers, particularly in cases where such species are imported for structural or allied applications, while ensuring that due consideration is given to relevant standards and treatment requirements.

Table 30 Mechanical Properties of Foreign Timber Species

(*Clause* A-1)

Sl No.	**Species**		**Locality from where Tested**	**Average Density at 12 Percent Moisture Content** kg/m^3	**Modulus of Elasticity (All Grades and All Locations) × 10^3** N/mm^2	**Permissible Stress**			
	Botanical Name	Trade Name				Bending-Tension Along Grain, Extreme Fibre Stress N/mm^2	Shear all Locations Horizontal N/mm^2	Compression Parallel to Grain N/mm^2	Compression Perpendicular to Grain N/mm^2
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(8)	(8)
i)	*Pseudotsuga menziesii*	Douglas fir (DF)	Pacific NW, USA	513	13.4	Inside: 11.0 Outside: 9.4 Wet: 9.4	1.24 (Inside) 1.05 (Outside)	Inside: 11.7 Outside: 9.9 Wet: 9.9	2.9
ii)	*Tsuga heterophylla*	Western hemlock (WH)	Pacific NW, USA	500	11.2	Inside: 9.3 Outside: 7.9 Wet: 7.9	1.03 (Inside) 0.88 (Outside)	Inside: 9.3 Outside: 7.9 Wet: 7.9	2.4

NOTE — The above data on foreign timber species is reproduced from the *USDA Wood Handbook* (*USA*). This information is for reference only. At present, no indigenous test data under Indian climatic and service conditions is available for these species. Therefore, before adopting them in structural applications in India, the properties should be verified through appropriate laboratory testing as per accepted standards.

LIST OF STANDARDS

The following list records those standards which are acceptable as 'good practice' and 'accepted standards' in the fulfilment of the requirements of this NBCS. The latest version of a standard shall be adopted at the time of the enforcement of this NBCS. The standards listed may be used for conformance with the requirements of the referred clauses in this NBCS.

In the following list, the number appearing in the first column within parenthesis indicates the number of the reference in this Subsection.

FOREWORD

This NBCS (Part C/Subsection 3B) covers the general principles involved in the design of structural bamboo in buildings with regard to mechanical resistance and durability of structures. Design of both bamboo (round bamboo, split bamboo, glued laminated bamboo) and bamboo-based panels joined together with adhesives or mechanical fasteners are covered in this Subsection. It also covers minimum strength data, dimensional stability, grading requirements and traditional bamboo joints for quality assurance. Constructional aspects using bamboo, such as, work on site, fabrication of components off-site and their erection on site is also covered to the extent necessary to indicate and ensure the quality of material and standard of workmanship to comply with the assumptions of the design rules and the limitations.

Bamboo is a versatile resource possessing high strength-to-weight ratio and cost ratio and offers considerable ease in working with simpler tools. It has a long and well established tradition as a building material. The application of bamboo as a constructional material is largely based on established traditions and intuitions of forefathers throughout the tropical and sub-tropical regions.

Resilience coupled with light weight makes bamboo an ideal material for housing in disaster prone/earthquake prone areas. It has the capacity to withstand repetitive loadings and absorb more energy and show larger deflections before collapse and as such is safer under earth tremors. As the design guidelines were inadequate, the application of bamboo as an engineering material was largely based on practical and engineering experience. A need was therefore felt to develop a Code for design and construction with bamboo so as to cater to a number of social and trade advantages, engineering recognition and the improved status of bamboo as an engineering material. This was achieved by adding a new chapter in the 2005 revision of this code, covering structural design with bamboo. Forest Research Institute, Dehradun and some other organizations were engaged in bamboo research to establish its silviculture, botanical, entomological and pathological aspects besides creating a utilization base. All these works were utilized in the preparation of the 2005 version of this Subsection of this

Some of the suitable species grown in India and neighbouring countries are enlisted in Annex A along with their local names and source, for general information.

The bamboo culm has a tubular structure consisting essentially of nodes and inter-nodes. In the inter-nodes the cells are axially oriented while the nodes provide the transverse inter-connection. The disposition of the nodes and the wall thickness are significant in imparting strength to bamboo against bending and crushing. In a circular cross-section, bamboo is generally hollow and for structural purposes this form is quite effective and advantageous. Each of the species of bamboo has widely different characteristics affecting its usefulness as constructional material. The strength of bamboo culms, their straightness, lightness combined with hardness, range and size of hollowness make them potentially suitable for a variety of applications both structural and non-structural. With good physical and mechanical properties, low shrinkage and good average density, bamboo is well suited to replace wood in several applications, especially in slats and panel form. Mass production of bamboo components, if required, may be integrated with treatment facilities near to the site of plantation or site of construction, for speed and economy in construction.

The Section on structural design with bamboo was first published in 2005 as a part of National Building Code of India under Subsection 3B of Part 6. In the 1983 version of this code, timber was covered under Section 3 of Part 6 ‘Structural Design’ under the title ‘Wood’, which did not cover bamboo. In the 2005 version of this code, the scope of Section 3 was enlarged as Section 3 ‘Timber and bamboo’, which was subdivided into Subsection 3A ‘Timber’ and Subsection 3B ‘Bamboo’. This Subsection pertains to 3B ‘Bamboo’.

Key changes to the 2016 version included: inclusion of provisions on construction practices using bamboo that was addressed in erstwhile Part 7 ‘Construction Management, Practices and Safety’; updated provisions for bamboo trusses, bamboo foundations; bamboo as reinforcement in concrete; introduction of the use of bamboo-based materials for walling, flooring, roofing, and in-fill panels, along with provisions for reconstituted wood from bamboo; and updates to the terms and definitions related to bamboo-based panel products.

With the standardization on design and construction aspects of bamboo in this Subsection of this code, it was expected to ensure durable structures, however, some specific guidelines were required in the event of tropical cyclones in the sub-continent and the traditional non-engineered structures generally constructed. Keeping this in view, some recommendations are given in Annex B which may be followed in addition to provisions given in the main text of this Subsection.

As a result of experience gained in implementation of 2016 version of this code and further research work done, feedback received as well as revision/updation of some of the existing standards, a need to revise this Subsection was felt. This revision has, therefore, been brought out to take care of these aspects.

In this revision, this publication has been renamed as National Building Construction Standards (NBCS).

The significant changes incorporated in this revision include the following:

a) Bamboo grading, in **4.4**, has been expanded to include special grades based on mean outer diameter;

b) Bamboo mat corrugated sheets (BMCS) are included, in **6.9.9**, as a sustainable roofing material with high strength, resilience, and thermal resistance for diverse climates;

c) Comprehensive life cycle assessment to evaluate environmental impacts from production to end-of-life of bamboo structures;

d) Annex C has been introduced illustrating conventional bamboo construction details such as trusses, roofing, walls, and flooring; and

e) References to all the concerned Indian Standards have been updated.

Reference may be made to Part F 'Fire and Life Safety' of this NBCS for fire protection of the bamboo buildings.

The information contained in this Subsection is largely based on the works carried out at Forest Research Institute, Dehradun; Institute of Wood Science and Technology, Bangalore; International Network for Bamboo and Rattan (INBAR) documents and Indian Standards given below. Assistance has also been derived from ISO 22156 : 2021 'Bamboo structures- Bamboo culms- Structural design', apart from the following:

IS 9096 : 2006	Preservation of bamboo for structural purpose — Code of practice
IS 15912 : 2018	Structural design using bamboo — Code of practice

All standards, whether given herein above or cross-referred to in the main text of this Subsection, are subject to revision. The parties to agreement based on this Subsection are encouraged to investigate the possibility of applying the most recent editions of the standards.

As the regulation of land development and buildings is a State subject and is dealt by the States and local bodies such as urban local bodies within their jurisdiction through building regulatory documents like building regulations, building byelaws, and fire regulations, this document is voluntary in nature and is non-binding. The implementation depends on adoption by concerned parties or stipulations in a contract or by appropriate adoption by the concerned authorities.

For the purpose of deciding whether a particular requirement of this Subsection is complied with, the final value, observed or calculated, expressing the result of a test or analysis, shall be rounded off in accordance with IS 2 : 2022 'Rules for rounding off numerical values (*second revision*)'. The number of significant places retained in the rounded off value should be the same as that of the specified value in this Subsection.

This Page has been Intentionally left blank

Important Explanatory Note for Users of this NBCS

In any Part/Section of this NBCS, where reference is made to **'good practice'** in relation to design, constructional procedures or other related information, and where reference is made to **"accepted standard"** in relation to material specification, testing, or other related information, the Indian Standards listed at the end of the Part/Section shall be used as a guide to the interpretation.

At the time of publication, the editions indicated in the standards were valid. All standards are subject to revision and parties to agreements based on any Part/Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

In the list of standards given at the end of a Part/Section, the number appearing within parentheses in the first column indicates the number of the reference of the standard in the Part/Section. For example:

a) Good practices [C-3B(1)] refers to the Indian Standard(s) give at serial number (1) of the list of standards given at the end of this Subsection, that is, IS 9096 : 2006, 'Code of practice for preservation of bamboo for structural purposes (*first revision*)'

NATIONAL BUILDING CONSTRUCTION STANDARDS

PART C STRUCTURAL DESIGN

SECTION 3 TIMBER AND BAMBOO: 3B BAMBOO

1 SCOPE

1.1 This NBCS (Part C/Subsection 3B) covers the general principles involved in the design of structural bamboo in buildings with regard to mechanical resistance and durability of structures. Design of both bamboo (round bamboo, split bamboo, glued laminated bamboo) and bamboo-based panels joined together with adhesives or mechanical fasteners are covered in this Subsection. It also covers minimum strength data, dimensional stability, grading requirements and traditional bamboo joints for quality assurance. Constructional aspects using bamboo, such as, work on site, fabrication of components off-site and their erection on site are also covered to the extent necessary to indicate and ensure the quality of material and standard of workmanship to comply with the assumptions of the design rules and the limitations.

1.2 The following aspects are not covered in this Subsection:

a) Limit state design and performance of structures; and

b) Scientific designing of bamboo joints and their fastenings.

2 TERMINOLOGY

For the purpose of this Subsection, the following definitions shall apply.

2.1 Anatomical Purpose Definitions

2.1.1 *Bamboo* — Tall perennial grasses found in tropical and sub-tropical regions. They belong to the family *Poaceae* and sub-family *Bambusoideae*.

2.1.2 *Bamboo Culm* — A single shoot of bamboo usually hollow except at nodes which are often swollen.

2.1.3 *Bamboo Clump* — A cluster of bamboo culms emanating from two or more rhizomes in the same place.

2.1.4 *Cellulose* — A carbohydrate, forming the fundamental material of all plants and a main source of the mechanical properties of biological materials.

2.1.5 *Cell* — A fundamental structural unit of plant and animal life, consisting of cytoplasm and usually enclosing a central nucleus and being surrounded by a membrane (animal) or a rigid cell wall (plant).

2.1.6 *Cross Wall* — A wall at the node closing the whole inside circumference and completely separating the hollow cavity below from that above (*Syn*. Diaphragm, that is, horizontal partition in a standing culm) (*see also* 2.2.19 and 2.2.32).

2.1.7 *Hemi Cellulose* — The polysaccharides consisting of only 150 to 200 sugar molecules, also much less than the 10 000 of cellulose.

2.1.8 *Lignin* — A polymer of phenyl propane units, in its simple form ($C_6H_5CH_3CH_2CH_3$).

2.1.9 *Sliver* — Thin strips of bamboo processed from bamboo culm.

2.1.10 *Tissue* — Group of cells, which in higher plants consist of (a) Parenchyma — a soft cell of higher plants as found in stem pith or fruit pulp, (b) Epidermis — the outermost layer of cells covering the surface of a plant, when there are several layers of tissue.

2.2 Structural Purpose Definitions

2.2.1 *Bamboo Mat Board* — A board made of two or more bamboo mats bonded with an adhesive.

2.2.2 *Bamboo Mat Corrugated Sheet* — A sheet made up of adhesive soaked and coated mats assembled and pressed under specified temperature and pressure to obtain sinusoidal or other suitable corrugations.

2.2.3 *Bamboo Mat Corrugated Sheets* (*BMCS*) — Roofing sheets made from woven bamboo mats, treated and pressed with resin to form a durable, weather-resistant corrugated material.

2.2.4 *Bamboo Mat Ridge Cap* (*BMRC*) — It is a specially shaped bamboo composite designed to cover and seal the ridge line of BMCS roofs, providing a weatherproof finish to the roof structure.

2.2.5 *Bamboo Mat Veneer Composite* — Panel manufactured with a combination of bamboo mat and veneer. Bamboo mat can be either as outer skins or as core/cross-bands. However, the composite panel shall be balanced construction on either side of central ply.

2.2.6 *Beam* — A structural member which supports load primarily by its internal resistance to bending.

2.2.7 *Breaking Strength* — A term loosely applied to a given structural member with respect to the ultimate load it can sustain under a given set of conditions.

2.2.8 *Bundle-Column* — A column consisting of three or more number of culms bound as integrated unit with wire or strap type of fastenings.

NOTE — During bunching of beams/columns, binders (5 mm tie bar/wire and 15 mm bamboo dowel pins) may be carefully inserted after proper pre-drilling the holes throughout the assembly as per the requirements of structural design.

2.2.9 *Centre Internode* — A test specimen having its centre between two nodes.

2.2.10 *Characteristic Load* — The value of load which has a 95 percent probability of not exceeding during the life of the structure.

2.2.11 *Characteristic Strength* — The strength of the material below which not more than 5 percent of the test results are expected to fall.

2.2.12 *Cleavability* — The ease with which bamboo can be split along the longitudinal axis. The action of splitting is known as cleavage.

2.2.13 *Column* — A structural member which supports axial load primarily by inducing compressive stress along the fibres.

2.2.14 *Common Rafter* — A roof member which supports roof battens and roof coverings, such as boarding and sheeting.

2.2.15 *Curvature* — The deviation from the straightness of the culm.

2.2.16 *Delamination* — Separation of mats through failure of glue.

2.2.17 *De-structured Bamboo* — Raw material (green bamboo) reduced partially to a condition, as far as practicable, in which the element fibres remain interlocked and in their highly aligned state and which with the help of binder can be reconstituted into a valuable product of a desirable size.

2.2.18 *End Distance* — The distance measured parallel to the fibres of the bamboo from the centre of the fastener to the closest end of the member.

2.2.19 *Flattened Bamboo* — Bamboo consisting of culms that have been cut and unfolded till it is flat. The culm thus is finally spread open, the diaphragms (cross walls) at nodes removed and pressed flat.

2.2.20 *Full Culm* — The naturally available circular section/shape.

2.2.21 *Fundamental or Ultimate Stress* — The stress which is determined on a specified type/size of culms of bamboo, in accordance with standard practice and does not take into account the effects of naturally occurring characteristics and other factors.

2.2.22 *Inner Diameter* — Diameter of internal cavity of a hollow piece of bamboo.

2.2.23 *Inside Location* — Position in buildings in which bamboo remains continuously dry or protected from weather.

2.2.24 *Joint* — A connection between two or more bamboo structural elements.

2.2.25 *Joist* — A small beam directly supporting floor, ceiling or roof of a structure.

2.2.26 *Length of Internode* — Distance between adjacent nodes.

2.2.27 *Loaded End or Compression End Distance* — The distance measured from the centre of the fastener to the end towards which the load induced by the fastener acts.

2.2.28 *Machette* — A light cutting and slashing tool in the form of a large knife.

2.2.29 *Mat* — A woven sheet made using thin slivers.

2.2.30 *Mortise and Tenon* — A joint in which the reduced end (tenon) of one member fits into the corresponding slot (mortise) of the other.

2.2.31 *Net Section* — Section obtained by deducting from the gross cross-section (A), the projected areas of all materials removed by boring, grooving or other means.

2.2.32 *Node* — The place in a bamboo culm where branches sprout and a diaphragm is inside the culm and the walls on both sides of node are thicker.

2.2.33 *Outer Diameter* — Diameter of a cross-section of a piece of bamboo measured from two opposite points on the outer surface.

2.2.33.1 *Mean outer diameter* — The diameter taken twice on the outer surface, in direction perpendicular to each other at each cross-section on both the ends. Thus, resulting in mean of four readings for the middle of culm.

2.2.34 *Outside Location* — Position in building in which bamboos are occasionally subjected to wetting and drying as in case of open sheds; and outdoor exposed structures.

2.2.35 *Permissible Stress* — Stress obtained after applying factor of safety to the ultimate stress. This is also the working stress unless adjusted to the particular structural form in design.

2.2.36 *Principal Rafter* — A roof member which supports purlins.

2.2.37 *Purlins* — A roof member directly supporting roof covering or common rafter and roof battens.

2.2.38 *Roof Battens* — A roof member directly supporting tiles, corrugated sheets, slates or other roofing materials.

2.2.39 *Roof Skeleton* — The skeleton consisting of bamboo truss or rafter over which solid bamboo purlins are laid and lashed to the rafter or top chord of a truss by means of galvanized iron wire, cane, grass, bamboo leaves, etc.

2.2.40 *Slenderness Ratio* — The ratio of the length of member to the least radius of gyration is known as slenderness ratio of member (the length of the member is the equivalent length due to end conditions).

2.2.41 *Splits* — The pieces made from quarters by dividing the quarters radially and cutting longitudinally.

2.2.42 *Taper* — The ratio of difference between minimum and maximum outer diameter to length.

2.2.43 *Unloaded End Distance* — The end distance opposite to the loaded end.

2.2.44 *Wall Thickness* — Half the difference between outer diameter and inner diameter of the piece at any cross section.

2.2.44.1 *Mean wall thickness* — The wall thickness taken four times in the same points as the diameter has been measured. Thus, resulting in mean of eight values for the middle of culm.

2.2.45 *Wet Location* — Position in buildings in which the bamboos are almost continuously damp, wet or in contact with earth or water, such as piles and bamboo foundations.

2.3 Definitions Relating to Defects

2.3.1 *Bamboo Bore/GHOON Hole* — The defect caused by bamboo ghoon beetle (*Dinoderus spp*. *Bostrichidae*), which attacks felled culms.

2.3.2 *Crookedness* — A localized deviation from the straightness in a piece of bamboo.

2.3.3 *Discolouration* — A change from the normal colour of the bamboo which does not impair the strength of bamboo or bamboo composite products.

2.4 Definition Relating to Drying Degrades

2.4.1 *Collapse* — The defect occurring on account of excessive shrinkage, particularly in thick walled immature bamboo. When the bamboo wall shrinks, the outer layers containing a larger concentration of strong fibro-vascular bundles set the weaker interior portion embedded in parenchyma in tension, causing the latter to develop cracks. The interior crack develops into a wide split resulting in a depression on the outer surface. This defect also reduces the structural strength of round bamboo.

2.4.2 *End Splitting* — A split at the end of a bamboo. This is not so common a defect as drying occurs both from outer and interior wall surfaces of bamboo as well as the end at the open ends.

2.4.3 *Surface Cracking* — Fine surface cracks not detrimental to strength. However, the cracking which occurs at the nodes reduces the structural strength.

2.4.4 *Wrinkled and Deformed Surface* — Deformation in cross section, during drying, which occurs in immature round bamboos of most species; in thick walled pieces, besides this deformation the outer surface becomes uneven and wrinkled. Very often the interior wall develops a crack below these wrinkles, running parallel to the axis.

3 SYMBOLS

For the purpose of this Subsection, the following letter symbols shall have the meaning indicated against each, unless otherwise stated:

A = cross-sectional area of bamboo (perpendicular to the direction of the principal fibres and vessels), mm^2

= $\frac{\pi}{4}[D^2-(D-2w)^2]$;

A_B = area of reinforcement in bamboo reinforced cement concrete, mm^2;

D = mean outer diameter of bamboo culm, mm;

d = inner diameter, mm

= $(D-2w)$;

E = modulus of elasticity (MOE) in bending, N/mm^2;

f_c = calculated stress in axial compression, N/mm^2;

f_{cp} = permissible stress in compression along the fibres, N/mm^2;

I = moment of inertia (the second moment of area) of culm section, mm^4

= $\frac{\pi}{64}[D^4-(D-2w)^4]$;

ℓ = unsupported length of column, mm;

m = moisture content, percent;

r = radius of gyration, mm

= $\sqrt{\frac{I}{A}}$;

R = modulus of rupture (MOR), N/mm^2;

w = mean of wall thickness of bamboo culm, mm;

Z = section modulus, mm^3

= $\frac{\pi}{32}\left[\frac{D^4-(D-2w)^4}{D}\right]$; and

δ = deflection or deformation, mm.

4 MATERIALS

The requirements shall be met by the choice of suitable materials, by appropriate design and detailing and by specifying control procedures for production, construction and use.

4.1 Species of Bamboo

More than 100 species of bamboo are native to India and a few of them are solid but most of them are hollow in structure. In all 20 species have been systematically tested so far. Sixteen species of bamboo are recommended for structural usages in round form. Some physical and mechanical properties of the same are given in Table 1 both for air-dry conditions and green conditions.

4.1.1 Matured bamboo of at least 4 years of age shall be used. The bamboo shall be used after at least six weeks of felling period.

4.1.2 Bamboo shall be properly treated in accordance with the good practice [C-3B(1)].

4.1.3 Solid bamboos or bamboos whose wall thickness is comparatively more and which are generally having nodes very closer are often considered good for structural purposes.

4.1.4 Broken, damaged or collapsed bamboo shall be rejected. Dead and immature bamboos, bore/*Ghoon* holes, decay, collapse, checks more than 3 mm in depth, shall be avoided.

4.2 Grouping

4.2.1 Sixteen species of bamboo recommended for structural applications are classified in three groups on the basis of their strength properties, namely, modulus of elasticity (E) in bending in green condition and modulus of rupture (R) (extreme fibre stress in bending). For structural use in piles and mines' components, an additional criterion of compressive strength is considered in classification. The limits in ultimate strength values of these groups shall be as given in Table 2 (these are corresponding to the spread of properties in structural timber).

4.2.2 Bamboo species may be identified using suitable methods.

NOTE — Methods of identification of bamboo through anatomical characters have not been perfected so far. Identification through morphological characters could be done only on full standing culm by experienced sorters.

4.2.3 Species of bamboo other than those listed in the Table 3 may be used, provided their strength characteristics are determined and found more than the limits specified in Table 2.

4.3 Moisture Content in Bamboo

Normally only dry or seasoned bamboo shall be used otherwise special attention shall be given to dimensional changes occurring during the drying process in the joints, assemblies.

With decrease of moisture content, the strength of bamboo increases exponentially and bamboo has an intersection point (fibre saturation point) at around 25 percent moisture content depending upon the species. A typical moisture strength relationship is given at Fig. 1. The moisture content of bamboo shall be determined in accordance with method given in the accepted standard [C-3B(2)]. Matured culms shall be seasoned to about 15 percent moisture content before use.

Freshly felled bamboo with shoots and leaves intact, dry fairly well in the open sun with lesser surface cracking, etc, and reduced starch contents. Rapid drying in the open can control degrades.

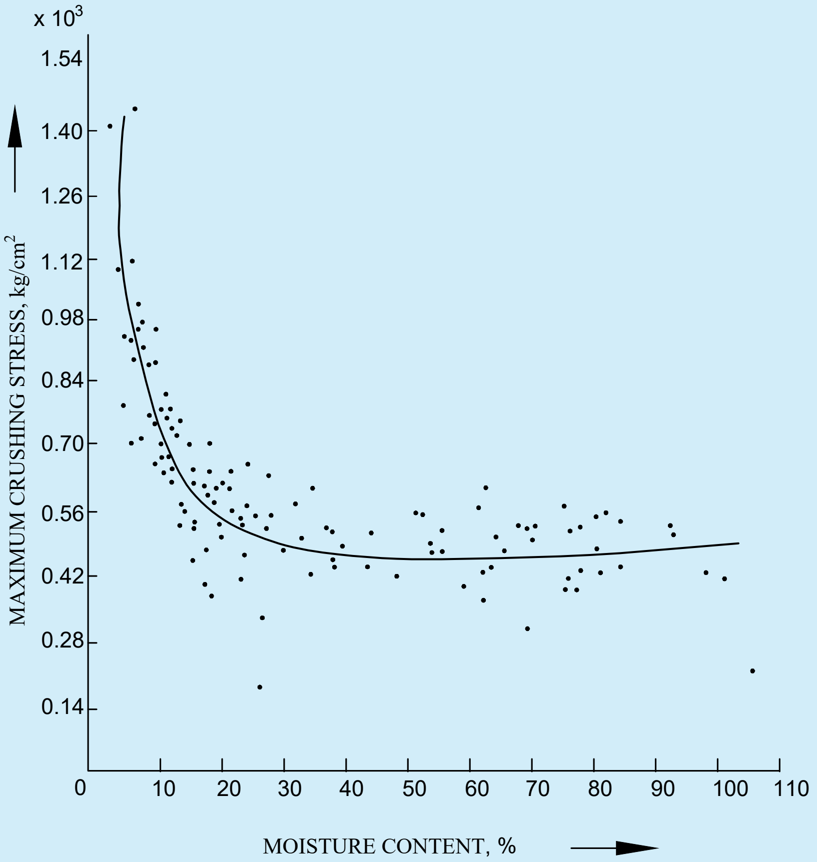

FIG. 1 MOISTURE STRENGTH RELATIONSHIP OF BAMBUSA NUTANS (BAMBOO)

4.4 Grading of Structural Bamboo

Bamboo shall be graded to ensure that the properties of bamboo are satisfactory for use, particularly the strength and stiffness properties. Grading bamboo is a process that ensures its structural integrity, standardization, efficient use, and marketability. It plays a crucial role in enhancing trade and promoting sustainable harvesting by ensuring that bamboo meets the required specifications for various applications. This process is essential for ultimately producing safe and economical structures, encouraging its use in mainstream construction and other industries.

4.4.1 Grading is sorting out bamboo on the basis of characteristics important for structural utilization as under:

a) Diameter and length of culm;

b) Taper of culm;

c) Straightness of culm;

d) Inter nodal length and distribution of nodes;

e) Wall thickness;
f) Density and strength; and
g) Durability and seasoning.

4.4.2 *Diameter and Length of Culm*

4.4.2.1 *Gradation according to the mean outer diameter*

For structural Group A and Group B species, culms shall be segregated in steps of 10 mm of mean outer diameter as follows:

a) Special grade A : 100 mm < Diameter ≤ 130 mm
b) Special grade B : 70 mm < Diameter ≤ 100 mm
c) Grade I : 50 mm < Diameter ≤ 70 mm
d) Grade II : 30 mm < Diameter ≤ 50 mm
e) Grade III : Diameter ≤ 30 mm

For structural Group C species culms shall be segregated in steps of 20 mm of mean outer diameter as follows:

a) Grade I : 80 mm < Diameter ≤ 100 mm
b) Grade II : 60 mm < Diameter ≤ 80 mm
c) Grade III : Diameter ≤ 60 mm

4.4.2.2 The minimum length of culms shall be preferably 4.5 m for facilitating close fittings at joints, etc.

4.4.3 *Taper*

The taper shall not be more than 5.8 mm per metre length (or 0.58 percent) (1 in 170) of bamboo in any grade of bamboo.

4.4.4 *Curvature*

The maximum curvature should not be more than 75 mm in a length of 6 m of any grade of bamboo.

NOTE — Due to the constraint of preferential selection of straighter material out of a lot, more bent material may be accommodated to avoid high cost. Following remedial options may be helpful:

a) Adopt component assembly method to take care of some degree of curvature (bunching done after holding components straight).
b) Cut longer bamboo components with less curvature out of taller bamboo and use cambered ones for shorter length components.

4.4.5 *Wall Thickness*

Preferably minimum wall thickness of 8 mm shall be used for load bearing members unless calculations and the availability dictate otherwise.

4.5 Durability and Treatability

4.5.1 *Durability*

The natural durability of bamboo is low and varies between 12 months and 36 months depending on the species and climatic conditions. In tropical countries the bio-deterioration is very severe. Bamboos are generally destroyed in about one to two years' time when used in the open and in contact with ground; while a service life of two to five years can be expected from bamboo when used under cover and out of contact with ground. The mechanical strength of bamboo deteriorates rapidly with the onset of fungal decay in the sclerenchymatous fibres. Split bamboo is more rapidly destroyed than round bamboo

4.5.2 Fire safety of bamboo structures shall be ensured, for which the treatment prescribed in 7.3.4 may be followed.

5 PERMISSIBLE STRESSES

5.1 Ultimate stress values of different species and groups of bamboo shall be determined according to the accepted standard [C-3B(2)]. These values shall then be divided by appropriate factors of safety to obtain permissible stresses to cover the effects of variability, long term loading, grade, location of use and expected dynamic loading.

NOTE — As an information, it may be noted that the method of test for split bamboos is covered in the accepted standard [C-3B(4)].

5.1.1 The strength factors for deriving safe working stresses of bamboo shall be as under:

a) Extreme fibre stress in beams : 4

b) Modulus of elasticity : 4.5

c) Maximum compressive stress parallel to grain/fibres : 3.5

5.2 The available data for the safe working stresses for 16 species of bamboos are given in Table 3.

5.3 For change in duration of load other than continuous (long-term), the permissible stresses given in Table 3 shall be multiplied by the modification factors given below:

a) For permanent loads : 1.0

b) For imposed or medium term loading (permanent + temporary load) : 1.25

c) For short term loading (permanent + temporary load + wind load) : 1.50

6 DESIGN CONSIDERATIONS

6.1 Basic Requirements

A structure shall be designed and constructed by personnel having the appropriate skill and experience in such a way that:

a) With acceptable probability, it will remain fit for the use for which it is required, having due regard to its intended life and costs;

b) With appropriate degree of reliability, it will sustain all forces and effects likely to occur during execution and use and have adequate durability in relation to maintenance costs;

c) The structure will be adequately maintained;

d) The structure will be used in accordance with design limit briefs;

e) All structural members, assemblies or framework in a building shall be capable of sustaining, without exceeding the limits of relevant stress specified, the worst combination of all loadings;

f) A fundamental aspect of design will be to determine the forces to which the structure/structural element might be subjected to, starting from the roof and working down to the soil by transferring the forces through various components and connections;

g) Accepted principles of mechanics for analysis and specified design procedures shall be applied (or) the design requirements may be satisfied by prototype testing;

h) Loads shall be in accordance with Part C ‘Structural Design, Section 1 Loads and Load Effects’ of this NBCS, keeping into consideration that permeability of walls, floors and roof made from bamboo cause internal pressure and can therefore affect the wind load factor; and

j) The worst combination and location of loads shall be considered for design. Also, wind and seismic forces shall not be considered to act simultaneously.

6.2 Unlike timber, bamboo properties do not relate well to species, being dependent among other factors, on position of the culm, geographic location and age. The practice in timber engineering is to base designs on safe working stresses (*see* Note) and the same may be adopted to bamboo with the limitations that traditional experience rather than precise calculations generally govern the detailing.

NOTE — Limit states are states beyond which the structure no longer satisfies the design performance requirements. Limit states are classified into ultimate limit state relating to collapse mode and serviceability limit states associated with deformations, vibrations, etc. Design is usually based on ultimate stages with partial factors of safety.

6.3 Age old traditional experience of construction with bamboo is to be well preserved as non-standard practices for similar situations considered as an informal based on general social pattern and wisdom. Confirmation of such structures be based on reports after they have sustained the severity of earthquakes, cyclones, etc, as criteria for recommendations by the evaluation by competent engineer/builder with adequate experience in the field.

6.4 Net Section

It is determined by passing a plane or a series of connected planes transversely through the members. Least net sectional area is used for calculating load carrying capacity of a member. In the design of an intermediate or a long column, gross section shall be used in calculating load carrying capacity of column.

6.5 Structural Components

6.5.1 Main structural applications in bamboo may include roofing and flooring, shear walls, wall panelling, beams, piles, columns, arches, etc. Both from the point of view of capacity and deformation, trusses and framed skeletons are much better options in bamboo.

6.5.2 *Peculiarity of Bamboo as a Design Material*

This shall be based on the principles of applied mechanics involving the following assumptions:

a) Elastic behaviour of bamboo, until failure (plastic behaviour being considered to be not significant);

b) Bamboo culms are analyzed as hollow-tube structures (not perfectly straight) member on mean diameter and mean wall thickness basis. Designing as a variable thickness hollow-tube structure is a bit complex;

c) Nodes do not occur at constant intervals;

d) Structural elements of bamboo shall be appropriately supported near the nodes of culm as and where the structural system demands. The joints in the design shall be located near nodes;

e) Bamboo structures are designed like any other conventional structural analysis taking care of details with regards to supports and joints; and the diameter, wall thickness and initial curvature; and

f) Joints shall be considered to generally act as a hinge or as pinned, unless substantiating data justify a fixed joint.

6.6 Flexural Members

6.6.1 All flexural members may be designed using the principles of beam theory.

NOTE — The tendency of bamboo beams to acquire larger deflections under long continual loading (including creep) has to be taken care of either by giving a factor of safety to E or by considering double the design dead loading in calculation of deflections.

6.6.2 The moment of inertia, I shall be determined as follows:

a) Outside diameter and the wall thickness shall be measured at both ends, correct up to 1 mm for diameter of culm and 0.1 mm for the wall thickness; and

b) With these values the mean diameter and the mean thickness for the middle of the beam shall be calculated and moment of inertia determined.

6.6.3 The maximum bending stress shall be calculated and should be within the allowable stress.

6.6.4 The deflection shall be within the prescribed limits. The initial curvature shall also be considered in the calculation of the deflection.

6.6.5 The shear stress in the neutral layer at the small end shall be checked, if the length of the beam is less than 25 times the diameter at that end.

6.6.6 Forces acting on a beam, being loads or reaction forces at supports, shall act in nodes or as near to nodes as by any means possible.

6.7 Columns (Predominantly Loaded in Axial Direction)

6.7.1 Columns and struts are essential components sustaining compressive forces in a structure. They transfer load to the supporting media.

6.7.2 Design of columns shall be based on one of the following two criteria:

a) Full scale buckling tests on the same species, size and other relevant variables; and

b) Calculations, based on the following:

   1) Moment of inertia shall be determined as per 6.6.2;

   2) For bamboo columns the best available straight bamboo culms shall be selected; and

   3) Bending stresses due to initial curvature, eccentricities and induced deflection shall be taken into account, in addition to those due to any lateral load.

   NOTE — Unlike timber, MOE has already been provided a factor of safety in case of bamboo. This is on the basis of studies on variability of MOR and MOE. In the case of timber, no factor of safety for MOE was used because there has been an understanding that there is no variability in MOE. Subsequently it was confirmed that MOE varies as the MOR and there is very strong, highly significant correlation between the two. In fact, this correlation has formed the basis of development of machine grading of timber world-over. However, somehow the practice of not giving factor of safety to MOE continued in Indian Standard. Later on when the standard on structural use of bamboo was formulated, factor of safety was given both in MOR and MOE on the basis of latest variability studies on strength of bamboo.

6.7.3 Buckling calculation shall be according to Euler, with a reduction to 90 percent of moment of inertia, to take into account the effect of the taper which shall be less than 1 : 170.

6.7.4 For strength and stability, larger diameter thick walled sections of bamboo with closely spaced nodes shall be used. Alternatively, smaller sections may be tied together as a bundle-column.

6.8 A single bamboo culm is not an optimum component to structurally design different load bearing members. Bunching of bamboo is inevitable to fabricate beams, columns, etc. There is no end to the number of culmns in bunching. However, different components pose manufacturing problems during assembly, which should be appropriately taken care of (*see also* Fig. 9D and Fig. 9E).

6.8.1 Following precautions shall be taken to avoid possible split/crack in walling of bamboo:

a) Maintaining a minimum 100 mm distance of the drills from the end of the main bamboo culms drilled;

b) Choosing drilling points preferably within 30 mm from node;

c) Maintaining the interference fit between bamboo body and binders as under:

   1) For wall thickness ≥ 8 mm : 0.25 to 0.30 mm; and

   2) For wall thickness < 8 mm : 0.20 to 0.25 mm.

d) The inserting ends of the dowel pins may be dressed as tapered (conical).

6.9 Assemblies and Roof Trusses

6.9.1 Elements in structure are generally built-up in the form of assembled members for which a triangle is a simple figure of stability. Besides sloped chords, parallel chord construction is also appropriate as external profile.

6.9.2 A truss is essentially a plane structure which is very stiff in the plane of the members, that is the plane in which it is expected to carry load, but very flexible in every other direction. Roof truss generally consists of a number of triangulated frames, the members of which are fastened at ends and the nature of stresses at joints is either tensile or compressive and designed as pin-ended joints (*see* Fig. 2A). Bamboo trusses may also be formed using bamboo mat board or bamboo mat-veneer composite or plywood gusset (*see* Fig. 2B).

6.9.3 Trusses shall be analysed for the determination of axial forces in members and the deformation of joints. For the influence of eccentricities, due allowance shall be made in design.

6.9.4 The truss height shall exceed 0.15 times the span in case of a triangular truss (pitched roofing) and 0.10 times the span in case of a rectangular (parallel) truss.

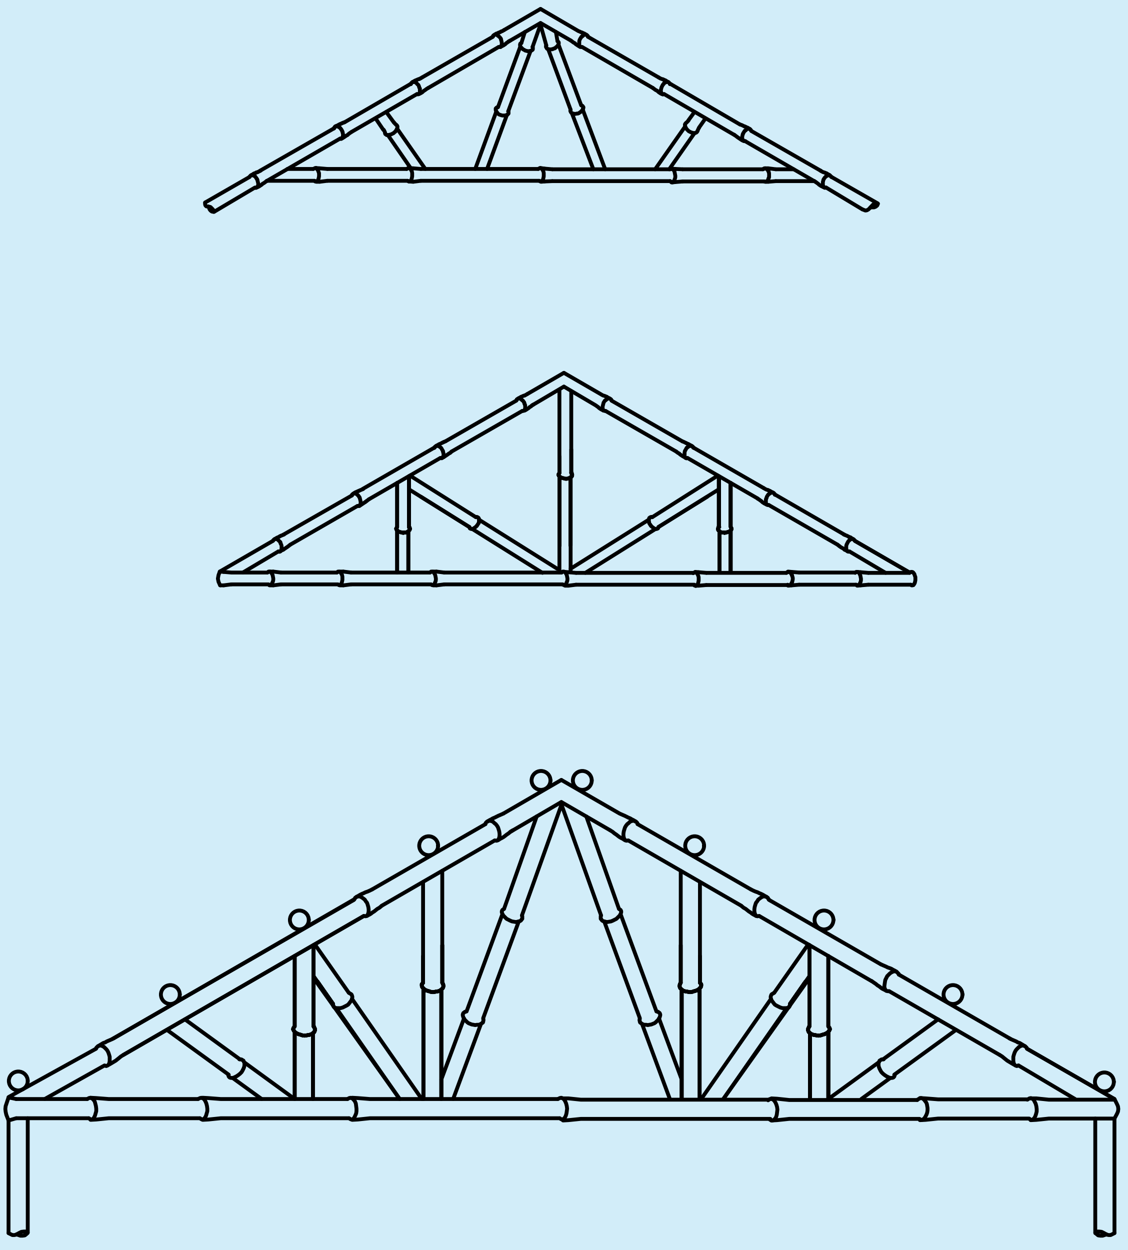
6.9.5 For members in compression, the effective length for in-plane strength verification shall be taken as the distance between two adjacent points of contraflexure. For fully triangulated trusses, effective length for simple span members without especially rigid end-connection shall be taken as the span length.

6.9.6 The spacing of trusses shall be consistent with use of bamboo purlins.

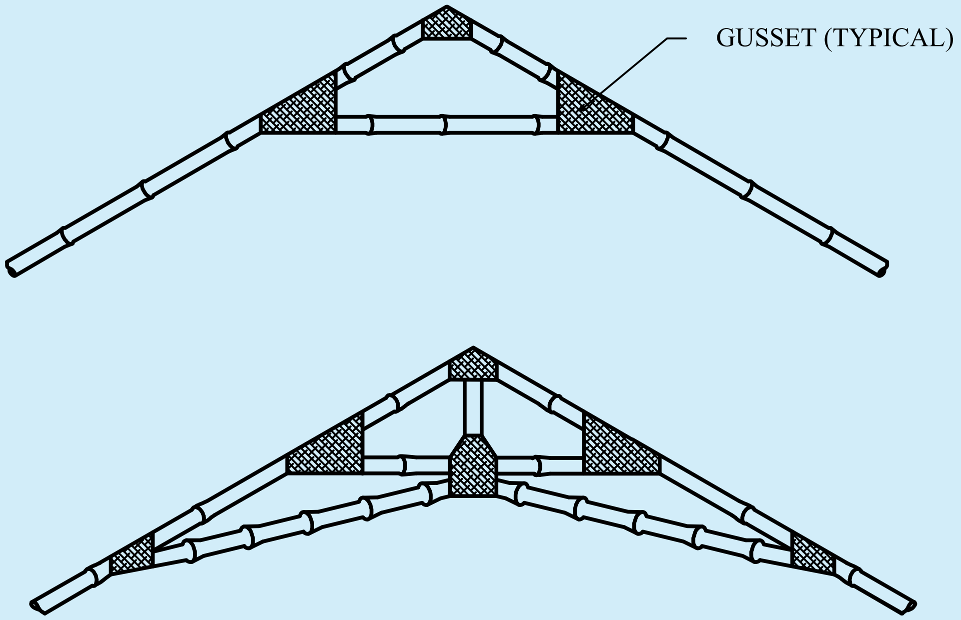
6.9.7 The ends in open beams, joists, rafters, purlins shall be suitably plugged. Bamboo roof coverings shall be considered as non-structural in function.

6.9.8 Bamboo trusses with wire bound joints using bamboo pins and/or wooden splice plates fastened with bamboo pins when tested at load for factor of safety of at least 5, result in deflection within permissible range at design load; good recovery but abnormal deflection beyond ultimate load without collapse was observed.

NOTE — This is based on the work done on prototypes of a few bamboo trusses (span 4 m) tested at Forest Research Institute, Dehradun.



2A PIN ENDED JOINT TRUSSES



2B GUSSET JOINT TRUSSES

FIG. 2 SOME TYPICAL CONFIGRATIONS FOR SMALL AND LARGE TRUSSES IN BAMBOO

6.9.9 *Bamboo Mat Corrugated Sheets for Building Roofs*

Bamboo mat corrugated sheets (BMCS) shall be used as a sustainable roofing material suitable for residential, commercial, and institutional buildings. BMCS are made from woven bamboo mats treated with phenolic resin and pressed under heat and pressure, these sheets offer a durable and eco-friendly alternative to traditional roofing materials. BMCS sheets shall provide high strength, resilience, and resistance to water, decay, and UV exposure, making them suitable for varied climates. These sheets should contribute to energy efficiency by offering thermal resistance and natural temperature regulation. BMCS shall comply with the accepted standard [C-3B(5)], meeting the necessary performance requirements for load-bearing capacity, impermeability, water absorption, and fire resistance.

6.9.10 *Bamboo Mat Ridge Cap (BMRC)*

Bamboo mat ridge cap (BMRC) is a sustainable, lightweight, and eco-friendly roofing solution developed to complement bamboo mat corrugated sheets (BMCS) in building construction. Produced from bamboo mats, BMRCs are designed to cover the ridge (top edges) of BMCS roofs, providing strong physical and mechanical properties suitable for roofing applications. BMRCs are energy-efficient and cost-effective, offering a high strength-to-weight ratio, low thermal conductivity, and an aesthetically pleasing appearance.

7 DESIGN, TECHNIQUES OF JOINTS AND CONSTRUCTION PRACTICES

7.1 Connecting the load-bearing elements together for effective transfer of stress and to achieve continuity between elements with controlled displacements is one of the serious problem. As joints are a source of weakness in any bamboo structure, they have to be made as strong and rigid as possible. Joints are quite critical in assemblies, and these should be stable in relation to time. For general information, the diagrams of typical joints given in Figs. 3 to 7 may be used based on tests for adequacy of strength.

FIG. 7 OTHER JOINTS AND SECTIONS

7.2 Bamboo Joints

Susceptibility to crushing at the open ends, splitting tendency, variation in diameter, wall thickness and straightness are some of the associated issues which have to be taken care of while designing and detailing the connections with bamboo.

Joints shall be designed to include force transmissions in a required manner, predictable deformations to be within prescribed limits and specific geometry/load direction.

Tests on full scale joints or on components shall be carried out in accordance with the good practice [C-3B(6)] and the accepted standards [C-3B(7)] as for nailed jointed timber structures.

7.2.1 *Traditional Practices*

Such joining methods revolve around lashing or tying by rope or string with or without pegs or dowels. Such joints lack stiffness and have low efficiency but have served the mankind for long in traditional bamboo construction.

7.2.1.1 *Lengthening joints* (*end jointing*) (*see* Fig. 3)

7.2.1.1.1 *Lap joint*

End of one piece of bamboo is made to lap over that of the other in line and the whole is suitably fastened. It may be full lapping or half lapping. Full section culms are overlapped by at least one internode and tied together in two or three places. Efficiency could be improved by using bamboo or hardwood dowels.

7.2.1.1.2 *Butt joints*

Culms of similar diameter are butted end to end, inter-connected by means of side plates made of quarter-round culm of slightly large diameter bamboo, for two or more internode lengths. Assembly shall be fixed and tied preferably with dowel pins.

7.2.1.1.3 *Sleeves and inserts*

Short length of bamboo of appropriate diameter may be used either externally or internally to join two culms together.

7.2.1.1.4 *Scarf joints*

A scarf joint is formed by cutting a sloping plane 1 in 4 to 1 in 6 on opposite sides from the ends of two similar diameter bamboo culms to be joined. They shall be lapped to form a continuous piece and the assembly suitably fastened by means of lashings or glued.

7.2.1.2 *Bearing joints* (*see Fig.* 4)

For members which either bear against the other or cross each other and transfer the loads at an angle other than parallel to the axis, bearing joints are formed.

7.2.1.2.1 *Saddle joints*

The simplest form consists of a horizontal member supported directly on top of a vertical member. The top of the post may be cut to form a saddle to ensure proper seating of beam for good load transfer. The saddle should be close to a node to reduce risk of splitting.

7.2.1.2.2 *Angled joints*

When two or more members meet or cross other than at right angles, angled joints are formed.

7.2.2 *Improved Practices in Bamboo Jointing*

7.2.2.1 Plywood or solid timber gusset plates may be used at joint assemblies of web and chord connection in a truss and fixed with bamboo pins or mild steel (MS) bolts. Hollow cavities of bamboo need to be stuffed with wooden plugs or otherwise by suitable means.

7.2.2.2 Use of wooden inserts to reinforce the ends of the bamboo before forming the joints. Alternatively, steel bands clamps with integral bolt/eye may be fitted around bamboo sections for jointing.

7.2.3 *Fixing Methods and Fastening Devices*

In case of butt joints the tie-wire may be passed through a pre-drilled hole or around hardwood or bamboo pegs or dowels inserted into preformed holes to act as horns. Pegs are driven from one side, usually at an angle to increase strength and dowels pass right through the member, usually at right angles. Normally 1.60 mm (16 SWG) diameter galvanized iron wire may be used for tight lashing.

NOTE — Drill size needs to be specified in order to avoid possible split/crack in walling of bamboo.

7.2.3.1 *Wire bound joints with or without pins*

Usually 2.00 mm (14 SWG) diameter galvanized iron wire is tightened around the joints by binding the respective pieces together. At least two holes are drilled in each piece and wire is passed through them for good results. Generally, 10 mm to 12 mm diameter bamboo pins are driven and fastened to culms.

7.2.3.2 *Fish plates/Gusset plated joints* (*see Fig.* 6)

At least 25 mm thick hardwood splice plate or 12 mm thick structural grade plywood are used. Solid bamboo pins help in fastening the assembly.

7.2.4 For any complete joint alternative for a given load and geometry, description of all fastening-elements, their sizes and location shall be indicated. Data shall be based on full scale tests.

7.2.5 Tests on full scale joints or on components shall be carried out in a recognized laboratory.

7.2.6 In case of high wind and seismic areas, good construction practices shall be followed taking care of joints, their damping and possible ductility. Bracings in walls shall be taken care of in bamboo structures.

7.2.7 Metal fasteners and other structural joints shall be made inherently corrosion resistant or be protected against corrosion, thereby making the joints more durable.

7.3 Construction Practices

7.3.1 Bamboo being a versatile resource characterized by high strength, low mass and ease of working with simple tools, it is desirable to increasingly make appropriate use of this material. Design of structures using bamboo should be done in accordance with **6**. It should be ensured that the elements of structure satisfy the appropriate fire resistance requirements as specified in Part F ‘Fire and Life Safety’ of this NBCS, and quality of building materials/components used shall be in accordance with Part B ‘Building Materials’ of this NBCS. For construction using bamboo, some of the important constructional provisions given in **7.3.2** to **7.3.7** shall be followed.

7.3.2 The following sound construction practices shall be taken into account:

a) Use of air dry bamboo; and ensure that bamboo in building remains air dry; and in case the bamboo has become wet, shall provide it the opportunity to dry again before the it deteriorates due to moisture;

b) Permeability of walls, floors and roofs made from bamboo, cause internal pressure and can therefore change the net wind-load acting on the roof, wall and floor; and

c) Check whether the workmanship of the labour force is according to the assumptions.

7.3.3 *Working Finishing*

7.3.3.1 Bamboo can be cut and split easily with very simple hand tools. Immature bamboos are soft, pliable and can be moulded to desired shape. It takes polish and paint well.

7.3.3.2 While it is possible to work with bamboo simply using a machete, a few basic tools such as, machete, hack saw, axe, hatchet, sharpening tools, adze, chisel (20 mm), drill, wood rasps, steel rod, and pliers, will greatly increase the effectiveness of the construction process.

7.3.4 For providing safety to the structure against fire, bamboo may be given fire retardant treatment using following chemicals; a few drops of concentrated Hcl shall be added to the solution to dissolve the precipitated salts:

Ammonium phosphate	:	3 parts
Boric acid	:	3 parts
Copper sulphate	:	1 part
Zinc chloride	:	5 parts
Sodium dichromate	:	3 parts
Water	:	100 parts

7.3.5 *Foundations*

Bamboo in direct contact with ground, bamboo on rock or preformed concrete footing, bamboo incorporated into concrete, may form the foundation structure (*see* Fig. 8). Also, arrangements with use of metallic strap, C-clamp and bunched bamboo columns embedded in concrete may be used for foundation of bamboo structures (*see* Fig. 9).

7.3.6 *Floors*

The floor of bamboo may be at ground level with covering of bamboo matting, etc. In elevated floors, bamboo members become an integral part of structural framework of building. The floor will comprise structural bamboo elements and bamboo decking.

7.3.7 *Jointing Techniques*

The jointing techniques in construction using bamboo shall be in accordance with 7.2.

8 BAMBOO AS REINFORCEMENT IN CONCRETE

8.1 Due to its fibrous texture, bamboo possesses high tensile strength. This can act as an alternate material for reinforcement in concrete within the limitations in design and construction. The ultimate strength of some of the species of bamboo in direct tension is nearly the same as that of steel at its yield point. On an average it varies from 1 400 kg/cm^{2}to 2 000 kg/cm^2. The principles adopted for design of concrete structure with steel is also applicable for the concrete member with bamboo. Strength characteristics of steel, concrete and bamboo are indicated in Table 4 and the design data for balanced section in beams/slabs reinforcement is given in Table 5.

Table 4 Strength Characteristics of Mild Steel, Bamboo and Concrete (For Reinforcement Purposes)

(*Clause* 8.1)

		Mild Steel	Bamboo (Green)	Mass Concrete
(1)	(2)	(3)	(4)	(5)
i)	Modulus of elasticity	2.1×10^6	175 750 to 196 640 (for all locations)	–
ii)	Tensile stress	1 265.5 to 1 400	158, Bending-tension (all locations)	–
iii)	Compressive stress	–	105 (*D. strictus*)	500
iv)	Bond stress	–	3.5 (green) to 5.6 (dry) reported (likely to increase up to 10)	40 to 100
v)	Shear stress	–	115 to 180	50

Table 5 Design Data for Bamboo and Mild Steel Reinforced Cement Concrete for Balanced Section

(*Clause* 8.1)

Sl No.	Design Parameter	Design Data for Balanced Section M 15 (1 : 2 : 4) Bamboo and Mild Steel Reinforced Cement	
		Mild Steel	Bamboo
(1)	(2)	(3)	(4)
i)	Modular ratio	18	1 to 1.4
ii)	Position of neutral axis from the top	0.4d	0.25d to 0.254d
iii)	Lever arm of the resisting moment (MOR)	0.87d	0.917d to 0.915d
iv)	Constant for MOR (Q) where Q= Bending moment/bd^2 , d=depth or thickness, and b= width.	137	86

8.2 The whole bamboo culms are halved longitudinally and again splitted into four and strips of the size of 20 mm to 25 mm width and 9 mm thickness are prepared for use as reinforcement. Bamboo strips with triangular lugs (formed at nodes) due to conversion of bamboo into strips improve the bond strength because of the protruding lugs beings gripped firmly in concrete. Strength properties of split bamboo out of a few species are given in Table 6.

8.3 Bamboo has a tendency to absorb water from concrete which results in initial swelling and subsequent shrinkage leading to cracks in concrete. Following processes are thus recommended as mandatory:

a) Chemical treatment with preference for pressure impregnation (Full cell treatment with warm coal tar creosote is likely to preserve and at the same time act as water repellent); and

b) Treated strips be further given a water repellent treatment with a coating of very hot bitumen 80/100 grade, followed by a liberal coating of coarse sand. Water inhibitor will also help maintain dimensional stability of strips.

8.4 Techniques in Placing the Reinforcement (*see also* Fig. 10)

Reinforcement shall be placed in the following manner:

a) Laid edge wise in sets of twin strips for main reinforcement;

b) Laid flatwise with smooth surface and rough surface alternating as distribution or subsidiary reinforcement (wedge effects increased bond);

c) For negative moments, bamboo strips of length equivalent to $\frac{span}{6}$ laid flatwise in alternate rows of slab reinforcement;

d) For beams and lintels, twin strips are arranged in tiers, placed one above the other depending upon requirement and held in position with the help of vertical strips;

e) Split bamboo strip or preferably steel rod be used for diagonal tension to resist shear in beams, etc; and

f) Bind the reinforcement with the help of galvanized iron binding wire (or nylon thread/bamboo-cane string).

9 WALLING, FLOORING, ROOFING, AND IN-FILL PANELS FOR WALL, AND COMMON ROOF COVERING/CLADDING MATERIALS

9.1 Materials

9.1.1 *Bamboo Based Panel Products*

The common roof covering and in-fill materials shall include bamboo mat board, bamboo mat veneer composite, bamboo mat corrugated sheet, bamboo tiles, plastered bamboo reeds, thatch, corrugated galvanized iron sheeting, asphaltic sheets, plain clay tiles, etc. The respective materials shall conform to the following:

a) *Bamboo mat board* — These shall conform to the accepted standard [C-3B(8)];

b) *Bamboo mat veneer composite* — These shall conform to the accepted standard [C-3B(9)];

c) *Bamboo mat corrugated sheet and bamboo mat ridge cap* — These shall conform to the accepted standard [C-3B(5)]; and

d) *Bamboo-jute composite corrugated and semi-corrugated sheets* — These shall conform to the accepted standard [C-3B(10)].

9.1.2 *Reconstituted Wood from Destructured Bamboo*

After lopping, bamboos are cross-cut into small lengths in the round and then split along the axis. The small cross-section strips are then passed between the counter revolving rollers till the material is fully destructured. This is then air dried and resin treated and suitably pressed without much disturbing the natural alignment of fibres thus retaining the directional properties of bamboo.

Some typical strength properties of reconstituted wood from destructured bamboo are given in Table 7. The reconstituted product from bamboo can be sawn, nailed, moulded, bored, screwed, polished and painted. Thus, it offers a good substitute of solid wood for structural uses.

NOTE — Reconstituted boards/wood from destructured bamboo when tested for physical and mechanical properties in accordance with the accepted standards [C-3B(11)] and [C-3B(12)] yielded encouraging results. Gist of mechanical properties of these boards is excellent when compared with *Dendrocalamus strictus* (bamboo), teak and sal.

Table 7 Gist of Mechanical Properties of Reconstituted Wood from Bamboo (*Dendrocalamus strictus*)

v)	*Dendrocalamus strictus*			0.757	1 310	–	624	–	–	180.3	–

9.1.3 *Other Panel Products/Infill Materials*

Other panel products/infill materials shall be in accordance with relevant Indian standards. These shall be such that they maintain their integrity and strength in the assigned service class throughout the expected life of the structure.

9.1.4 *Adhesives*

Adhesive shall maintain their integrity in accordance with the accepted standard [C-3B(13)].

9.2 Structural Usage of Bamboo Based Products

9.2.1 *General*

Bamboo mat board (BMB) and bamboo mat veneer composite (BMVC) have high in-plane rigidity and hence high racking strength and are more flexible than equivalent plywood. This property of BMB and BMVC can be advantageously used in many engineering applications such as wall panelling, composite beams, composite floor deck and stress skinned panels. Bamboo mat corrugated sheet (BMCS) is water proof and resistant to decay, termites/insects and fire. These sheets may be used as roofing material. Precast bamboo reinforced cement concrete and reconstituted wood from destructured bamboo can also be used in structural applications.

9.2.2 *Bamboo Composites*

Along with bamboo, bamboo composites such as bamboo mat board, bamboo mat veneer composite, may also be successfully used in combination with timber for making efficient structural components like web because where high shear strength of bamboo mat board and bamboo mat veneer composite can be utilized as web and timber flanges for transmitting tensile and compressive stress. PF, PRF adhesives are commonly used for gluing web and flanges as shown in Fig. 11. Beams can be straight, single tapered, double tapered, haunched, as shown.

Bamboo mat board and bamboo mat veneer composite can also be used for roof and wall sheathing (shear walls) and diaphragms, gussets, arch panels, barrel vaults, etc. It can also be used as skin material in sandwich construction.

Permissible safe working stresses are given in Table 8.

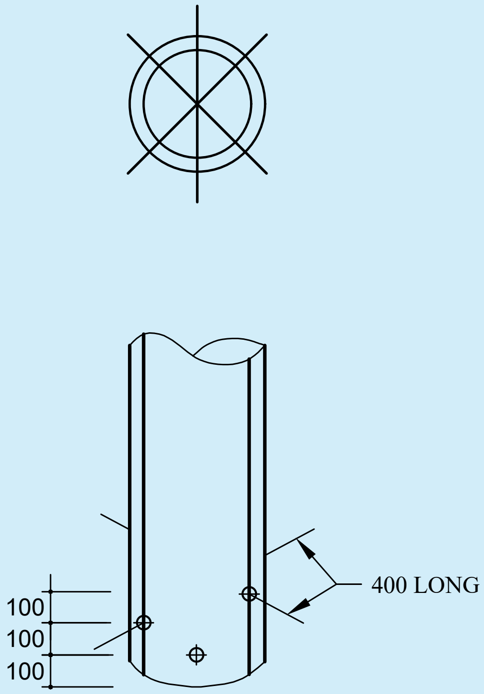
9.2.4.1 *Foundation detail*

The columns pierced by steel dowels at 150 mm centre-to-centre provide connection to the bamboo grid infill. Fix 8 mm diameter MS rod of 400 mm length at 100 mm from one end of the column which has undergone treatment. For anchoring, fix two more MS rods of same diameter at 100 mm centre-to-centre starting from the first hole (*see* Fig. 13). Pour the concrete by giving temporary support. Foundation is limited to individual footings of size 400 mm × 400 mm × 600 mm deep for each bamboo column placed at 1 200 mm apart and two coarse concrete blocks or stone or other locally available material for infill wall foundation.



All dimensions in millimetres

FIG. 13 DETAILS OF BOTTOM OF BAMBOO COLUMN FOR ANCHORING IN CONCRETE FOR FOUNDATION

9.2.5 *Bamboo Concrete Flooring Using Round Bamboo*

Technology of such a flooring (for situations needing raised flooring) is based on the method of rigidly fixing round bamboo, where 30 mm thick M20 grade PCC (with 6 mm down coarse aggregate) is placed over 6 mm to 8 mm thick culm, that are arranged side by side to form bamboo flooring.

The rigid fixing is achieved by using shear connectors in the form of 1.5 mm dia. 20 mm long MS nails partially inserted into the bamboo flooring and balance length with the heads of the nails embedded in the PCC layer, holding the two components together. The sectional properties of the combination are calculated based on the concept of flitched beams for design (*see* Fig. 14).

FIG. 14 DETAIL OF A TYPICAL BAMBOO CONCRETE FLOORING

9.2.6 *Bamboo Concrete Walling Using Flat Bamboo*

Loads on walls and roof do not generally justify use of round bamboo as such. So, flat or split bamboo is preferred for use in these cases. The flat bamboo works like a wire-net used conventionally to hold cement plaster in critical applications. Partial plastering is done during the first day ensuring entry of plastering material in the gaps of flat bamboo. This provides the base for cement plastering or PCC laying next day. About 5 mm gap is essential for entry of plastering material of sufficient sectional area to sustain shear force. The gaps are generated by inserting a small wedge of bamboo strip and pulling it out after a part of the gap is filled by plaster. Such gaps have to be discontinuous, to retain the character of a wire-net. About 25 percent width of the flat bamboo is assumed to be gaps, part of it is the organized gap of 5 mm width as described, at an interval of about 50 mm width, to sustain shear force and the balance gap remains to be natural to flat bamboo. Minimum thickness of the flat bamboo is assumed to be 6 mm. Bamboo with thicker wall would be stronger.

Expected strength (using *Bambusa balcooa*) may be considered as follows:

a) Walling of 6 mm bamboo with 18 mm thick cement sand plaster in 1 : 3 would be able to withstand wind pressure of 112 kgf/m^2 if used as wall, either supported continuously 1.5 m apart, or supported simply 1.25 m apart; and

b) As a roof, the wind suction load would be partly compensated by the dead load of the roof. The imposed load of a mason sitting at the centre of span needs to be considered. This load can be accommodated by use of 18 mm M 20 PCC with 6 mm flat bamboo, supported 1.0 m apart; neatly finished.

The engineered houses for application of the above bamboo concrete walling are designed with stiffeners and diagonals in all the three planes, keeping the deformation of walls along plane of walls almost nil and deflection of columns across the plane of wall at a minimum.

10 LIFE CYCLE ASSESSMENT OF BAMBOO FOR USE IN BUILDINGS

10.1 Timber used in building structures and elements shall undergo a comprehensive life cycle assessment (LCA) to evaluate its environmental impacts across its entire lifecycle, from raw material extraction to disposal or recycling. LCA provides valuable insights into the sustainability of timber and its environmental footprint in building applications. The assessment shall cover the following stages:

a) *Production and Construction* — This stage evaluates the energy and resources required for the extraction, transportation, and processing of raw timber into building materials. It also includes the energy consumption and waste generated during the construction process, as well as the transportation of materials to the construction site.

b) *Use Stage* — The use stage assesses the environmental impacts of timber during the building's operational lifespan. This includes maintenance, repairs, and potential replacement of timber components, considering the durability, performance, and long-term sustainability of the material.

c) *End-of-Life* — At the end of the building's useful life, the timber structure may undergo demolition, with the materials being processed for waste management, recycling, or reuse. This stage assesses the environmental effects of these processes and the potential for timber materials to be repurposed.

d) *Externalized Impacts Beyond the System Boundary* — The incidental effects of recycling, reusing, and recovering energy, water, or materials beyond the system boundaries of the LCA study are included in this stage. These externalized impacts consider how recycled timber or materials might contribute to environmental benefits outside the building's lifecycle.

10.2 Environmental Impact Categories

The LCA may be used to assess the environmental impact of timber buildings in several categories, which encompass emissions and pollutants generated throughout the lifecycle. These categories include:

a) *Global Warming Potential* — The contribution of greenhouse gas emissions to climate change;

b) *Acidification Potential* — The potential for acidic compounds to form in the environment, affecting ecosystems and infrastructure;

c) *Eutrophication Potential* — The impact of nutrient loading on water bodies, potentially causing excessive algal growth;

d) *Ozone Depletion Potential* — The impact of substances that contribute to the depletion of the ozone layer.

e) *Smog Formation Potential* — The potential for air pollution to contribute to the formation of ground-level ozone and smog; and

All relevant material and process quantities shall be included in the LCA inventory, and their impacts shall be calculated using recognized tools and methodologies.

10.3 Requirements for Life Cycle Assessment

In the context of building with timber, LCA may be required for the following purposes:

a) *Decision-Making Support* — Providing building owners and stakeholders with data on the environmental and sustainability aspects of timber, aiding informed decision-making;

b) *Design Evaluation* — Offering insights into material selection and environmental performance across different design possibilities;

c) *Product Comparison* — Demonstrating the environmental advantages of timber in comparison to alternative building materials;

d) *Environmental Benefit Evaluation* — Helping assess the ecological benefits of innovative timber products or policies; and

e) *Performance Benchmarking* — Comparing the environmental performance of timber buildings against established benchmarks and sustainability goals.

10.4 Methodology for Conducting LCA

The LCA of timber buildings may be conducted iteratively, with increasing detail as the design or construction phases progress. The process should follow these steps:

a) Establish the purpose and scope of the LCA, focusing on the objectives of evaluating timber's environmental impact;

b) Gather data on the timber materials, including their types, quantities, lifespans, and lifecycle stages. Special attention should be given to materials used in the production and use stages;

c) Using LCA tools (for example, SimaPro, MATLAB), assess the environmental impacts of timber buildings. The evaluation shall include biogenic carbon considerations, as timber stores carbon from the atmosphere, contributing to carbon sequestration during its lifecycle;

d) Interpret the LCA results by categorizing environmental impacts by building component, material type, and lifecycle stage. Identify key contributors to the building's overall environmental footprint and visualize the outcomes; and

e) Document all findings, including assumptions, methodology, and conclusions, and present the results in reports for stakeholders. The results shall guide sustainable construction practices and decision-making in timber building projects.

10.5 Reporting

The results of the LCA should be documented, including all assumptions, methodologies, and conclusions. Reports should be prepared in accordance with relevant standards, and may be used to guide sustainable building practices and decision-making in construction.

11 TYPICAL DETAILS OF CONVENTIONAL BAMBOO BUILDING CONSTRUCTION

Typical details of conventional bamboo building construction is given in Annex C, for guidance.

ANNEX A

(*Foreword*)

SOURCE AND LOCAL NAMES OF SOME OF THE SPECIES OF BAMBOO

Sl No. (1)	*Species* (2)	*Source/Local Names* (3)
i)	*Bambusa auriculata*	Assam, Bangladesh, Myanmar; introduced in Calcutta Botanical Garden.
ii)	*B. balcooa*	Asm – Baluka; Ben – Balku bans; Duars – Bora bans; Garo – Wamnah, beru; Tripura – Barak.
iii)	*B. bambos* (*Syn.B. arundinacea*)	Asm – Kotoba; Ben – Baroowa, behor, ketuas, ketwa; Manip – Saneibi; Mah – Katang bamboo, oowga; Oriya – Daba, katuig; Tel – Mulkasveduru, Mulluvedurn; English – Spiny bamboo.

2 The above table does not provide an exhaustive list. It only attempts to enlist some of the information readily available in regard to species of bamboo from India and some of the neighbouring countries, and some connected information.

ANNEX B

(*Foreword*)

RECOMMENDATIONS FOR BAMBOO STRUCTURES IN HIGH WIND/CYCLONE PRONE AREAS

B-1 Given below are some recommendations for bamboo structures in high wind/cyclone prone areas, which are based on rapid visual screening (RVS) of the damages of past events:

a) Prefer a square plan of the building symmetrical to the arrangement of partitions and openings for balanced distribution of forces within the structure. Window positioning be planned in such a way that wind entering through window could pass through similar opening on opposite wall in order to reduce built-up pressure, and incorporate ridge vents;

b) A hip-shaped, pyramidal or a conical roofing be preferred to gable end or mono-pitch ones for least wind resistance;

c) Wide mono-pitched *verandas* abutting the entrance to residence should be structurally separated from the main building;

d) Roof overhangs be limited to 450 mm as they contribute to higher negative suction. Large overhangs should be properly tied back to wall frame-work;

e) Roof structure shall be properly secured with vertical load-bearing members (wooden or bamboo columns, brick piers or walling) for eliminating the chances of being blown away from the building. A continuous beam connecting all the columns would increase the framing action;

f) Roof cladding (G.I. sheets, clay tiles or thatch) be properly connected with holding down U-bolts, or sturdy anchorages to ensure safety. Thatch roof be tied by nylon ropes in diagonal pattern;

g) Sufficient depth for anchorage be provided; columns be embedded in pits within the foundation and secured by poured concrete. Wetting of column base be checked by raising it from the floor level;

h) Highest importance be given to strengthening the junctions between structural elements at different levels, that is, foundation, eaves and roof. Walls be linked together suitably by a continued collar beam at floor, sill, lintel and roof level; and

j) Fastening any two mutually perpendicular load bearing members should be done in accordance with good practice of spacing the connecting bolts with reference to loads direction and the centre of stiffness. This will increase the moment-resisting capacity of the joint and prevent hinge formation. A minimum of two bolts be provided to prevent rotation of members at a joint.

LIST OF STANDARDS

The following list records those standards which are acceptable as 'good practice' and 'accepted standards' in the fulfilment of the requirements of this NBCS. The latest version of the standard shall be adopted at the time of enforcement of this NBCS. The standards listed may be used for conformance with the requirements of the referred clauses in this NBCS.

In the following list, the number appearing in the first column within parenthesis indicates the number of the reference in this Subsection.

	IS No.	*Title*

FOREWORD

This NBCS (Part C/Section 4) covers the structural design of unreinforced and reinforced masonry elements in buildings. Provisions on reinforced brick and reinforced brick concrete floors and roofs have also been dealt with.

This Section was first published in 1970 and subsequently revised in 1983, 2005 and 2016 as a chapter of National Building Code of India. The first revision of this Section was modified in 1987 through Amendment No. 2 to bring this Section in line with the latest revised masonry code. In the amendment, certain provisions were updated following the revision of IS 1905 'Code of practice for structural use of unreinforced masonry' on which the earlier version was based. In the amendment, requirements of masonry element for stability were modified; in the design of free standing wall, provisions were made for taking advantage of the tensile resistance in masonry under certain conditions; provision regarding effective height of masonry wall between openings was modified; method of working out effective height of wall with a membrane type DPC was modified; the criteria for working out effective length of wall having openings was modified; some general guidelines for dealing with concentrated loads for design of walls were included; and provision of cutting and chases in walls were amplified. The Section was thereafter revised in 2005.

In the second revision of this Section in 2005, the provisions of special considerations in earthquake zones were aligned in line with the revised Indian Standard, IS 4326 : 1993 'Code of practice for earthquake resistant design and construction of buildings'; a new clause covering guidelines for improving earthquake resistance of low strength masonry buildings was added; and reference to design of reinforced brick and reinforced brick concrete floors and roofs was included.

In the third revision of this Section in 2016, the detailed provisions relating to reinforced masonry and durability criteria for selection of masonry mortars had been included. Also, the number of storeys of masonry construction had been limited to 4, in line with the seismic design standards. A new masonry wall construction using rat-trap bond had been included.

In this revision, this publication has been renamed as National Building Construction Standards (NBCS).

As a result of experience gained in the implementation of this Section and feedback received, as well as in view of formulation of new varieties of cement and new types of masonry blocks, a need to revise this Section was again felt. This section has, therefore, been revised to incorporate the following significant changes:

1) New masonry blocks have been included as masonry unit.
2) The admissibility of different structural systems in the earthquake zones is clarified. The following structural systems are admissible to construct earthquake resistant masonry buildings:
    a) Masonry walls with prescriptive bands (MWB);
    b) Masonry walls with prescriptive bands and vertical reinforcement (MWBR);
    c) Confined masonry walls (CMW); and
    d) Reinforced masonry walls (RMW).
3) The clause on confined masonry has been updated.
4) The clause on reinforced masonry has been updated.
5) Reference to all the concerned Indian Standards has been updated.

Structural design requirements of this section are largely based on following Indian Standards:

a) IS 1905 : 1987 'Code of practice for structural use of unreinforced masonry (*third revision*)';
b) IS 4326 : 2013 'Earthquake resistant design and construction of buildings — Code of practice (*third revision*)';

c) IS 10440 :1983 ‘Code of practice for construction of RB and RBC floors and roofs’; and

d) IS 17848 : 2022 ‘Confined masonry for earthquake resistance — Code of practice’.

Buildings with MWB and MWBR systems shall not be of height more than 15 m subject to a maximum of four storeys, measured from the base of the buildings to the roof slab or ridge level.

A reference to SP 20 : 1991 ‘Handbook on masonry design and construction (*first revision*)’, may be useful. In the formulation of this Section, inputs were also derived from the IITK-GSDMA’s publication, ‘Guidelines for structural use of reinforced masonry’.

All standards, whether given herein above or cross-referred to in the main text of this section, are subject to revision. The parties to agreement based on this section are encouraged to investigate the possibility of applying the most recent editions of the standards.

As the regulation of land development and buildings is a State subject and is dealt by the States and local bodies such as urban local bodies within their jurisdiction through building regulatory documents like building regulations, building byelaws, and fire regulations, this document is voluntary in nature and is non-binding. The implementation depends on adoption by concerned parties or stipulations in a contract or by appropriate adoption by the concerned authorities.

For the purpose of deciding whether a particular requirement of this Section is complied with, the final value, observed or calculated, expressing the result of a test or analysis, shall be rounded off in accordance with IS 2 : 2022 ‘Rules for rounding off numerical values (*second revision*)’. The number of significant places retained in the rounded off value should be the same as that of the specified value in this Section.

Important Explanatory Note for Users of the NBCS

In any Part/Section of this NBCS, where reference is made to **'good practice'** in relation to design, constructional procedures or other related information, and where reference is made to **'accepted standard'** in relation to material specification, testing, or other related information, the Indian Standards listed at the end of the Part/Section shall be used as a guide to the interpretation.

At the time of publication, the editions indicated in the standards were valid. All standards are subject to revision and parties to agreements based on any Part/Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

In the list of standards given at the end of a Part/Section, the number appearing within parentheses in the first column indicates the number of the reference of the standard in the Part/Section. For example:

a) Accepted standards [C-4(1)] refers to the Indian Standard(s) give at serial number (1) of the list of standards given at the end of this Part C/Section 4, that is, IS 1077 : 1992 'Specification for common burnt clay building bricks (*fifth revision*)', IS 1725 : 2023 'Specification for stabilized soil blocks used in general building construction (*third revision*)', IS 2180 : 1988 'Specification for heavy duty burnt clay building bricks (*third revision*)', IS 2185 (Part 1) : 2005 'Concrete masonry units — Specification: Part 1 Hollow and solid concrete blocks (*third revision*)', IS 2185 (Part 2) : 1983 'Concrete masonry units — Specification: Part 2 Hollow and solid light weight concrete blocks (*first revision*) (superseding IS 3590)', IS 2185 (Part 3) : 1984 'Concrete masonry units— Specification: Part 3 Autoclaved cellular (aerated) concrete blocks (*first revision*)(superseding IS 5482)', IS 2185 (Part 4) : 2008 'Concrete masonry units — Specification: Part 4 Cellular preformed foam cellular concrete blocks', IS 2222 : 1991 'Specification for burnt clay perforated building bricks (*fourth revision*)', IS 2849 : 1983 'Specification for non-load bearing gypsum partition blocks (solid and hollow types)(*first revision*)', IS 3115 : 1992 'Specification for lime based blocks (*second revision*)', IS 3316 : 1974 'Specification for structural granite (*first revision*)', IS 3620 : 1979 'Specification for laterite stone block for masonry (*first revision*)', IS 3952 : 2013 'Burnt clay hollow bricks and blocks for walls and partitions — Specification (*third revision*)', IS 4139 : 1989 'Specification for calcium silicate bricks (*second revision*)', IS 12440 : 1988 'Specification for precast concrete stone masonry blocks', IS 12894 : 2002 'Specification for pulverized fuel ash lime bricks (*first revision*)', IS 13757 : 1993 'Specification for burnt clay fly ash building bricks' and IS 16720 : 2018 'Pulverized fuel ash-cement bricks — Specification'.

b) Good practice [C-4(4)] refers to the Indian Standard(s) give at serial number (4) of the list of standards given at the end of this Part C/Section 4, that is,IS 2250 : 1981 'Code of practice for preparation and use of masonry mortars (*first revision*)'.

NATIONAL BUILDING CONSTRUCTION STANDARDS

PART C STRUCTURAL DESIGN

SECTION 4 MASONRY

1 SCOPE

1.1 This NBCS (Part C/Section 4) covers the structural design aspects of unreinforced load bearing and non-load bearing walls, constructed with masonry units permitted in accordance with this Section.

1.2 This Section also deals with the selection of materials, special features of design and construction for masonry construction using rectangular masonry units. It also covers guidelines regarding earthquake resistant buildings constructed using masonry of low strength.

1.3 This Section also covers provisions for design of reinforced brick and reinforced brick concrete floors and roofs.

1.4 This Section also gives the recommendations for structural design aspects of reinforced load bearing and non-load bearing walls, constructed with different types of bricks and blocks.

1.5 The recommendations of the Section do not apply to walls constructed in mud mortars.

2 TERMINOLOGY

For the purpose of this Section, the following definitions shall apply.

2.1 Bed Block — A block bedded on a wall, column or pier to disperse a concentrated load on a masonry element.

2.2 Bond — Arrangement of masonry units in successive courses to tie the masonry together both longitudinally and transversely; the arrangement is usually worked out to ensure that no vertical joint of one course is exactly over the one in the next course above or below it, and there is maximum possible amount of lap.

2.3 Column, Pier and Buttress

a) *Column* — An isolated vertical load bearing member, width of which does not exceed four times the thickness;

b) *Pier* — A thickened section forming integral part of a wall placed at intervals along the wall, to increase the stiffness of the wall or to carry a vertical concentrated load. Thickness of a pier is the overall thickness including the thickness of the wall or, when bonded into a leaf of a cavity wall, the thickness obtained by treating that leaf as an independent wall (*see* Fig. 1)

c) *Buttress* — A pier of masonry built as an integral part of wall and projecting from either or both surfaces, decreasing in cross-sectional area from base to top.

2.4 Cross-Sectional Area of Masonry Unit — Net cross-sectional area of a masonry unit shall be taken as the gross cross-sectional area minus the area of cellular space. Gross cross-sectional area of cored units shall be determined to the outside of the coring but cross-sectional area of grooves shall not be deducted from the gross cross-sectional area to obtain the net cross-sectional area.

2.5 Curtain Wall — A non-load bearing wall subject to lateral loads. It may be laterally supported by vertical or horizontal structural members, where necessary (*see* Fig. 2).

2.6 Effective Height — The height of a wall or column, to be considered for calculating slenderness ratio.

2.7 Effective Length — The length of a wall to be considered for calculating slenderness ratio.

2.8 Effective Thickness — The thickness of a wall or column to be considered for calculating slenderness ratio.

2.9 Hollow Unit — A masonry unit of which net cross-sectional area in any plane parallel to the bearing surface is less than 75 percent of its gross cross-sectional area measured in the same plane.

RCC SLAB
HINGED JOINT (DIAGRAMMATIC)
RCC COLUMN
CURTAIN WALL

NOTE — The figure is only illustrative to explain about the term curtain wall and is not intended to be an exhaustive provision.

FIG. 2 TYPICAL MASONRY CURTAIN WALL

2.10 Grout — Mortar of pourable consistency.

2.11 Joint — A junction of masonry units, which can be classified as:

a) *Bed Joint* — A horizontal mortar joint upon which masonry units are laid;

b) *Cross Joint* — A vertical joint, normal to the face of the wall; and

c) *Wall Joint* — A vertical joint parallel to the face of the wall.

2.12 Leaf — Inner or outer section of a cavity wall.

2.13 Lateral Support — A support which enables a masonry element to resist lateral load and/or restrains lateral deflection of a masonry element at the point of support.

2.14 Load Bearing Wall — A wall designed to carry an imposed vertical load in addition to its own weight, together with any lateral load.

2.15 Masonry — An assemblage of masonry units properly bonded together with mortar.

2.16 Masonry Unit — Individual units which are bonded together with the help of mortar to form a masonry element such as wall, column, pier, buttress, etc.

2.17 Partition Wall — An interior non-load bearing wall, one storey or part storey in height.

2.18 Panel Wall — An exterior non-load bearing wall in framed construction, wholly supported at each storey but subjected to lateral loads.

2.19 Shear Wall — A wall designed to carry horizontal forces acting in its plane with or without vertical imposed loads.

2.20 Slenderness Ratio — Ratio of effective height or effective length to effective thickness of a masonry element.

2.21 Types of Walls

a) *Cavity Wall* — A wall comprising two leaves, each leaf being built of masonry units and separated by a cavity and tied together with metal ties or bonding units to ensure that the two leaves act as one structural unit, the space between the leaves being either left as continuous cavity or filled with a non-load bearing insulating and water-proofing material;

b) *Faced Wall* — A wall in which facing and backing of two different materials are bonded together to ensure common action under load (*see* Fig. 3).

NOTE — To ensure monolithic action in faced walls, shear strength between the facing and the backing shall be provided by toothing, bonding or other means; and

c) *Veneered Wall* — A wall in which the facing is attached to the backing but not so bonded as to result in a common action under load.

2.22 Reinforced Brick Slab (RB Slab) — Reinforced brick slab is particularly same as reinforced concrete slab in all its essential features except that brickwork is substituted partly for cement concrete. *See* Fig. 4(A) for details.

2.23 Reinforced Brick Concrete Slab (RBC Slab) — These are reinforced brick slab using concrete in the joints and on the top of bricks. *See* Fig. 4(B) for details.

3 MATERIALS

3.1 General

The materials used in masonry construction shall be in accordance with Part B 'Building Materials' of this NBCS. Storage of materials shall be in accordance with good practice [C-4(2)].

3.2 Masonry Units

Masonry units used in construction shall conform to accepted standards [C-4(1)].

FIG. 4(B) CROSS-SECTION OF RBC SLAB

FIG. 4 CROSS-SECTIONS OF RB AND RBC SLABS

3.2.1 Masonry units may be of the following types:

a) Common burnt clay building bricks;
b) Burnt clay fly ash building bricks;
c) Pulverized fuel ash lime bricks;
d) Pulverized fuel ash cement bricks;
e) Stones (in regular sized units);
f) Sand-lime bricks;
g) Concrete blocks (solid and hollow);
h) Lime based blocks;
j) Burnt clay hollow blocks;
k) Gypsum partition blocks,
m) Autoclaved cellular concrete blocks;
n) Stabilized soil blocks; and
p) Concrete stone masonry blocks.

NOTES

1 Gypsum partition blocks are used only for construction of non-load bearing partition walls.

2 Use of other masonry units such as precast stone blocks, fly-ash-lime-gypsum bricks, stabilized soil blocks and other bricks/blocks not covered by the above specifications may also be permitted based on test results.

3.2.2 Masonry units that have been previously used shall not be reused in brickwork or blockwork construction, unless they have been thoroughly cleaned and conform to this Section for similar new masonry units.

3.3 Mortar

Mortar for masonry shall conform to accepted standard [C-4(3)].

3.3.1 Minimum compressive strength for different grades of mortar on the basis of mix proportions as per **3.3.2** are given in Table 1.

3.3.2 Mix proportions and compressive strengths of some of the commonly used mortars are given in Table 2.

Table 1 Compressive Strength for Different Grades of Mortar

(*Clauses* 3.3.1, 3.4.1, 5.4.3, G-4.1 *and* Table 9)

Sl No.	Grade of Mortar	Minimum Compressive Strength at 28 Days N/mm^2
(1)	(2)	(3)
i)	H1	10
ii)	H2	6.0
iii)	M1	5.0
iv)	M2	3.0
v)	M3	1.5
vi)	L1	0.7
vii)	L2	0.5

3.4 Durability Criteria for Selection of Masonry Mortars

3.4.1 The selection of masonry mortars from durability considerations shall cover both the loading and exposure conditions of the masonry. The requirements for masonry mortar shall generally be as given in **3.4.2** to **3.4.6** (*see also* Table 1).

3.4.2 In the case of masonry exposed frequently to rains and where there is further protection by way of plastering or rendering or other finishes, the grade of mortar shall not be less than M3 but shall preferably be of grade M2. Where no protection is provided, the grade of mortar for external walls shall not be less than M2.

3.4.3 In the case of load bearing internal walls, the grade of mortar shall preferably be M3 or more for high durability but in no case less than L1.

3.4.4 In the case of masonry in foundations laid below damp-proof course, the grades of mortar for use in masonry shall be as specified below:

a) Where soil has little moisture, masonry mortar of grade not less M3 shall be used;

b) Where soil is very damp, masonry mortar of grade preferably M2 or more shall be used. But in no case shall the grade of mortar be less than L1 and M3; and

c) Where soil is saturated with water, masonry mortar of grade M1 shall be used but in no case shall the grade of mortar be less than M2.

3.4.5 For masonry in buildings subject to vibration of machinery, the grade of mortar shall not be less than M1.

3.4.6 For parapets, where the height is greater than three times the thickness, the grade of masonry mortar used shall not be less than M1. In the case of low parapets, the grade of mortar shall be the same as that used in the wall masonry below.

3.4.7 The grade of mortar for bedding joints in masonry with large concrete blocks shall not be less than M1.

4 DESIGN CONSIDERATIONS

4.1 General

Masonry structures gain stability from the support offered by cross walls, floors, roof and other elements such as piers and buttresses. Load bearing walls are structurally more efficient when the load is uniformly distributed and the structure is so planned that eccentricity of loading on the members is as small as possible. Avoidance of eccentric loading by providing adequate bearing of floor/roof on the walls providing adequate stiffness in slabs and avoiding fixity at the supports, etc, is especially important in load bearing walls in multistorey structures. These matters should receive careful consideration during the planning stage of masonry structures.

4.2 Lateral Supports and Stability

4.2.1 *Lateral Supports*

Lateral supports for a masonry element such as load bearing wall or column are intended,

a) to limit slenderness of a masonry element so as to prevent or reduce possibility of buckling of the member due to vertical loads; and

b) to resist horizontal components of forces so as to ensure stability of a structure against overturning.

4.2.1.1 Lateral support may be in the vertical or horizontal direction, the former consisting of floor/roof bearing on the wall or properly anchored to the same and latter consisting of cross walls, piers or buttresses.

Table 2 Mix Proportions and Strength of Mortars for Masonry

(*Clause* 3.3.2 *and* Table 23)

7(c)	0	0	1(LP-7)	0	1 ½	0.5	—

NOTES

1 Sand for making mortar should be well graded. In case sand is not well graded, its proportions shall be reduced in order to achieve the minimum specified strength.

2 For mixes in Sl No. 1 and Sl No. 2, use of lime is not essential from consideration of strength as it does not result in increase in strength. However, its use is highly recommended since if improves workability.

3 For mixes in Sl No. 3(a), 4(a), 5(a) and 6(a) either lime C or B to the extent of ¼ part of cement (by mass) or some plasticizer should be added for improving workability.

4 For mixes in Sl No. 4(b) and 5(b), lime and sand should first be ground in mortar mill and then cement added to coarse stuff.

5 It is essential that mixes in Sl No. 4(c), 4(d), 5(d), 5(e), 6(b), 6(c), 7(a) and 7(b) are prepared by grinding in a mortar mill.

6 A, B and C denote eminently hydraulic lime, semi-hydraulic lime and fat lime respectively, as specified in appropriate standards listed in Part B ‘Building Materials’ of this NBCS.

4.2.1.2 Requirements of **4.2.1**(a) from consideration of slenderness may be deemed to have been met with, if:

a) in case of a wall, where slenderness ratio is based on effective height, any of the following constructions are provided;

   1) RCC floor/roof slab (or beams and slab) irrespective of the direction of span, bears on the supported wall as well as cross walls, to the extent of at least 90 mm;

   2) RCC floor/roof slab not bearing on the supported wall or cross wall is anchored to it with non-corrodible metal ties of 600 mm length and of section not less than 6 mm × 30 mm, and at intervals not exceeding 2 m, as shown in Fig. 5; and

   3) Timber floor/roof, anchored by non-corrodible metal ties of length 600 mm and of minimum section 6 mm × 30 mm, securely fastened to joists and built into walls as shown in Fig. 6 and Fig. 7. The anchors shall be provided in the direction of span of timber joists as well as in its perpendicular direction, at intervals of not more than 2 m in buildings up to two storeys and 1.25 m for buildings more than two storeys in height.

   NOTES

   1 In case precast RCC units are used for floors and roofs, it is necessary to interconnect them and suitably anchor them to the cross walls so that they can transfer lateral forces to the cross walls.

   2 In case of small houses of conventional designs, not exceeding two storeys in height, stiffening effect of partitions and cross walls is such that metal anchors are normally not necessary in case of timber floor/roof and precast RCC floor/roof units.

b) in case of a wall, when slenderness ratio is based on its effective length; a cross wall/pier/buttress of thickness equal to or more than half the thickness of the supported wall or 90 mm, whichever is more, and length equal to or more than one fifth of the height of wall, is built at right angle to the wall (*see* Fig. 8) and bonded to it according to provision of **4.2.2.2** (**d**);

c) in case of a column, an RCC or timber beam/RS joist/roof truss, is supported on the column. In this case, the column will not be deemed to be laterally supported in the direction at right angle to it; and

d) in case of a column, an RCC beam forming a part of beam and slab construction is supported on the column, and slab adequately bears on stiffening walls. This construction will provide lateral support to the column, in the direction of both horizontal axes.

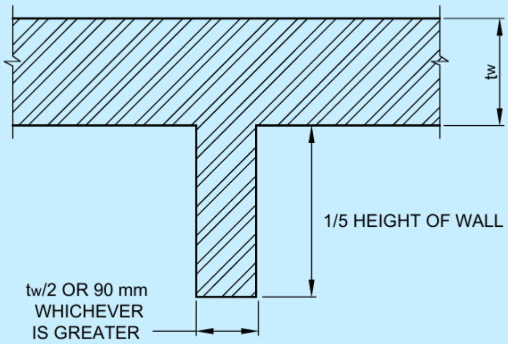

FIG. 8 MINIMUM DIMENSION FOR MASONRY WALL OR BUTTRESS EFFECTIVE LATERAL SUPPORT

4.2.2 *Stability*

A wall or column subjected to vertical and lateral loads may be considered to be provided with adequate lateral support from consideration of stability, if the construction providing the support is capable of resisting some of the following forces:

a) Simple static reactions at the point of lateral support to all the lateral loads; plus

b) 2.5 percent of the total vertical load that the wall or column is designed to carry at the point of lateral support.

4.2.2.1 For the purpose specified in **4.2.2**, if the lateral supports are in the vertical direction, these should meet the requirements given in **4.2.1.2** (a) and should also be capable of acting as horizontal girders duly anchored to the cross wall so as to transmit the lateral loads to the foundations without exceeding the permissible stresses in the cross walls.

4.2.2.2 In case of load bearing buildings up to four storeys, stability requirements of **4.2.2** may be deemed to have been met with, if:

a) height to width ratio of building does not exceed 2;

b) cross walls acting as stiffening walls continuous from outer wall to outer wall or outer wall to a load bearing inner wall, and of thickness and spacings as given in Table 3 are provided. If stiffening wall or walls that are in a line, are interrupted by openings, length of solid wall or walls in the zone of the wall that is to be stiffened shall be at least one-fifth of height of the opening as shown in Fig. 9;

c) floors and roof either bear on cross walls or are anchored to those walls as in **4.2.1.2** such that all lateral loads are safely transmitted to those walls and through them to the foundation; and

d) cross walls are built jointly with the bearing walls and are jointly mortared, or the two interconnected by toothing. Alternatively, cross walls may be anchored to walls to be supported by ties of non-corrodible metal of minimum section 6 mm × 35 mm and length 600 mm with ends bend at least 50 mm; maximum vertical spacing of ties being 1.2 m (*see* Fig. 10).

4.2.2.3 In case of halls exceeding 8.0 m in length, safety and adequacy of lateral supports shall always be checked by structural analysis.

4.2.2.4 A trussed roofing may not provide lateral support unless special measures are adopted to brace and anchor the roofing. However, in case of residential and similar buildings of conventional design with trussed roofing having cross walls, it may be assumed that stability requirements are met with by the cross walls and structural analysis for stability may be dispensed with.

4.2.2.5 Capacity of a cross wall, also called shear wall, sometimes to take horizontal loads and consequently bending moments increases, when parts of bearing walls act as flanges to the cross wall. Maximum overhanging length of bearing wall which could effectively function as a flange should be taken as 12*t* or *H*/6, whichever is less in case of *T/I* shaped walls, and 6*t* or *H*/16, whichever is less in case of *L/U* shaped walls, where *t* is the thickness of bearing wall and *H* is the total height of wall above the level being considered, as shown in Fig. 11.

4.2.2.6 *External walls of basement and plinth*

In case of external walls of basement and plinth, stability requirements of **4.2.2** may be deemed to have been met with, if:

a) bricks used in basement and plinth have a minimum crushing strength of 5 N/mm^2 and mortar used in masonry is of Grade M1 or better;

b) clear height of ceiling in basement does not exceed 2.6 m;

c) walls are stiffened according to provisions of **4.2.2.1**;

d) in the zone of action of soil pressure on basement walls, traffic load excluding any surcharge due to adjoining buildings does not exceed 5 kN/m^2 and terrain does not rise; and

e) minimum thickness of basement walls is in accordance with Table 4. However, if percentage opening in the basement wall for purposes like ventilation are more than 25 percent, then stability analysis/check need to be performed particularly for resistance to seismic loads.

NOTE — In case there is surcharge on basement walls from adjoining buildings, thickness of basement walls shall be based on structural analysis.

4.2.2.7 *Walls mainly subjected to lateral loads*

a) *Free standing wall* — A free standing wall such as compound wall or parapet wall is acted upon by wind force which tends to overturn it. This tendency to over-turning is resisted by gravity force due to self-weight of wall, and also by flexural moment of resistance on account of tensile strength of masonry. Free standing walls shall thus be designed as in **5.5.2.1**. If mortar used for masonry cannot be relied upon for taking flexural tension (*see* **5.4.2**), stability of free standing wall shall be ensured such that stability moment of wall due to self-weight equals or exceeds 1.5 times the overturning moment; and

b) *Retaining wall* — Stability for retaining walls shall normally be achieved through gravity action but flexural moment of resistance could also be taken advantage of under special circumstances at the discretion of the designer (*see* **5.4.2**).

ii)	Up to 2 m	Up to 2.5 m	400 mm

4.3 Effective Height

4.3.1 *Wall*

Effective height of a wall shall be taken as shown in Table 5 (*see* Fig. 12).

NOTE — A roof truss or beam supported on a column meeting the requirements of **4.2.2.1** is deemed to provide lateral support to the column only in the direction of the beam/truss.

FIG. 11 TYPICAL DETAILS FOR ANCHORAGE OF SOLID WALLS

Table 5 Effective Height of Walls

(*Clause* 4.3.1, 8.7.9.3, Table 22 *and* Table 23)

Sl No. (1)	**Condition of Support** (2)	**Effective Height** (3)
i)	Lateral as well as rotational restraint (that is, full restraint) at top and bottom. For example, when the floor/roof spans on the walls so that reaction to load of floor/roof is provided by the walls, or when an RCC floor/roof has bearing on the wall (minimum 90 mm), irrespective of the direction of the span foundation footings of a wall give lateral as well as rotational restraint	0.75 *H*
ii)	Lateral as well as rotational restraint (that is, full restraint) at one end and only lateral restraint (that is, partial restraint) at the other. For example, RCC floor/roof at one end spanning or adequately bearing on the wall and timber floor/roof not spanning on wall, but adequately anchored to it, on the other end	0.85 *H*
iii)	Lateral restraint, without rotational restraint (that is, partial restraint) on both ends. For example, timber floor/roof, not spanning on the wall but adequately anchored to it on both ends of the wall, that is, top and bottom	1.00 *H*
iv)	Lateral restraint as well as rotational restraint (that is, full restraint) at bottom but have no restraint at the top. For example, parapet walls with RCC roof having adequate bearing on the lower wall, or a compound wall with proper foundation on the soil.	1.50 *H*

Table 5 (*Concluded*)

NOTES

1 *H* is the height of wall between centres of support in case of RCC slabs and timber floors. In case of footings or foundation block, height (*H*) is measured from top of footing or foundation block. In case of roof truss, height (*H*) is measured up to bottom of the tie beam. In case of beam and slab construction, height should be measured from centre of bottom slab to centre of top beam. All these cases are illustrated by means of examples shown in Fig. 12.

2 For working out effective height, it is assumed that concrete DPC, when properly bonded with masonry, does not cause discontinuity in the wall.

3 Where membrane type damp-proof course or termite shield causes a discontinuity in bond, the effective height of wall may be taken to be greater of the two values calculated as follows:

a) Consider *H* from top of footing ignoring DPC and take effective height as 0.75 *H*; and

b) Consider *H* from top of DPC and take effective height as 0.85 *H*.

4 When assessing effective height of walls, floors not adequately anchored to walls shall not be considered as providing lateral support to such walls.

5 When thickness of a wall bonded to a pier is at least two-thirds of the thickness of the pier measured in the same direction, the wall and pier may be deemed to act as one structural element.

FIG. 13 EFFECTIVE HEIGHT OF WALL

4.3.2 *Column*

In case of a column, effective height shall be taken as actual height for the direction it is laterally supported and as twice the actual height for the direction it is not laterally supported (*see* Fig. 13).

NOTES

1 A roof truss or beam supported on a column meeting the requirements of **4.2.2.1** is deemed to provide lateral support to the column only in the direction of the beam/truss.

2 When floor or roof consisting of RCC beams and slabs is supported on columns, the columns would be deemed to be laterally supported in both directions.

4.3.3 *Openings in Walls*

When openings occur in a wall such that masonry between the openings is by definition a column, effective height of masonry between the openings shall be reckoned as follows:

a) *When wall has full restraint at the top*:

   1) Effective height for the direction perpendicular to plane of wall equals 0.75 H plus 0.25 H_1, where H is the distance between supports and H_1 is the height of the taller opening; and

   2) Effective height for the direction parallel to the wall equals H, that is, the distance between the supports.

b) *When wall has partial restraint at the top and bottom:*

   1) Effective height for the direction perpendicular to plane of wall equals H when height of neither opening exceeds 0.5 H and it is equal to 2 H when height of any opening exceeds 0.5 H; and

   2) Effective height for the direction parallel to the plane of the wall equals 2 H.

4.4 Effective Length

Effective length of a wall shall be as given in Table 6.

4.5 Effective Thickness

Effective thickness to be used for calculating slenderness ratio of a wall or column shall be obtained as in **4.5.1** to **4.5.5**.

4.5.1 For solid walls, faced walls or columns, effective thickness shall be the actual thickness.

4.5.2 For solid walls adequately bonded into piers, buttresses, effective thickness for determining slenderness ratio based on effective height shall be the actual thickness of wall multiplied by stiffening coefficient as given in Table 7. No modification in effective thickness, however, shall be made when slenderness ratio is to be based on effective length of walls.

Table 6 Effective Length of Walls

(*Clauses* 4.4)

Sl No. (1)	Conditions of Support (*See* Fig. 14) (2)	Effective Length (3)
i)	Where a wall is continuous and is supported by cross wall and there is no opening within a distance of $H/8$ from the face of cross wall (*see* Fig. 14) or Where a wall is continuous and is supported by piers/buttresses conforming to **4.2.1.2 (b)**	0.8 L
ii)	Where a wall is supported by a cross wall at one end and continuous with cross wall at other end or Where a wall is supported by a pier/buttress at one end and continuous with pier/buttress at other end conforming to **4.2.1.2 (b)**	0.9 L
iii)	Where a wall is supported at each end by cross wall or Where a wall is supported at each end by a pier/buttress conforming to **4.2.1.2 (b)**	1.0 L
iv)	Where a wall is free at one end and continuous with a pier/buttress at the other end or Where a wall is free at one end and continuous with a pier/buttress at the other end conforming to **4.2.1.2 (b)**	1.5 L
v)	Where a wall is free at one end and supported at the other end by a cross wall or Where a wall is free at one end and supported at the other end by a pier/buttress conforming to **4.2.1.2 (b)**	2.0 L

where

L = length of wall from or between centres of cross wall, piers or buttress; and

H = actual height of wall between centres of adequate lateral support.

NOTE — In case there is an opening taller than 0.5 H in a wall, ends of the wall at the opening shall be considered as free. Cross walls shall conform to **4.2.2.2 (d)**.

4.5.3 For solid walls or faced walls stiffened by cross walls, appropriate stiffening coefficient may be determined from Table 7 on the assumption that the cross walls are equivalent to piers of width equal to the thickness of the cross wall and of thickness equal to three times the thickness of stiffened wall.

4.5.4 For cavity walls with both leaves of uniform thickness throughout, effective thickness shall be taken as two-thirds of the sum of the actual thickness of the two leaves.

4.5.5 For cavity walls with one or both leaves adequately bonded into piers, buttresses or cross walls at intervals, the effective thickness of the cavity wall shall be two-thirds of the sum of the effective thickness of each of the two leaves; the effective thickness of each leaf being calculated using **4.5.1** or **4.5.2** as appropriate.

Table 7 Stiffening Coefficient for Walls Stiffened by Piers, Buttresses or Cross Walls

(*Clauses* 4.5.2 *and* 4.5.3)

Sl No.	**Ratio** $\frac{S_p}{w_p}$	**Stiffening Coefficient**		
		$\frac{t_p}{t_w} = 1$	$\frac{t_p}{t_w} = 2$	$\frac{t_p}{t_w} = 3$ or more

iii)	10	1.0	1.2	1.4
iv)	15	1.0	1.1	1.2
v)	20 or more	1.0	1.0	1.0

where

S_p = centre-to-centre spacing of the pier or cross wall;

t_p = thickness of pier as defined in **2.3** (**b**) (*see* Fig. 1);

t_w = actual thickness of the wall proper (*see* Fig. 1); and

w_p = width of the pier in the direction of the wall or the actual thickness of the cross wall.

NOTE — Linear interpolation between the values given in this table is permissible but not extrapolation outside the limits given.

4.6 Slenderness Ratio

4.6.1 *Walls*

For a wall, slenderness ratio shall be effective height divided by effective thickness or, effective length divided by the effective thickness, whichever is less. In case of a load bearing wall, slenderness ratio shall not exceed that given in Table 8. To reduce the slenderness ratio one and a half brick thick wall shall be up to ground level.

4.6.2 *Columns*

For a column, slenderness ratio shall be taken to be the greater of the ratios of effective heights to the respective effective thickness, in the two principal directions. Slenderness ratio for a load bearing column shall not exceed **12**.

4.7 Eccentricity

Eccentricity of vertical loading at a particular junction in a masonry wall shall depend on factors, such as extent of bearing, magnitude of loads, stiffness of slab or beam, fixity at the support and constructional details at junctions. No exact calculations are possible to make accurate assessment of eccentricity. Extent of eccentricity under any particular circumstances has, therefore, to be decided according to the best judgment of the designer. Some guidelines for assessment of eccentricity are given in Annex A.

5 STRUCTURAL DESIGN

5.1 General

The building as a whole shall be analysed by accepted principles of mechanics to ensure safe and proper functioning in service of its component parts in relation to the whole building. All component parts of the structure shall be capable of sustaining the most adverse combinations of loads, which the building may be reasonably expected to be subjected to during and after construction.

5.2 Design Loads

Loads to be taken into consideration for designing masonry components of a structure are:

a) dead loads of walls, columns, floors and roofs;

b) imposed loads of floors and roof;

c) wind loads on walls and sloping roof; and

d) seismic forces.

NOTE — When a building is subjected to other loads, such as vibration from railways; machinery, etc, these should be taken into consideration accordingly to the best judgment of the designer (*see also* Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS).

5.2.1 The design loads and other forces to be taken for the design of masonry structures shall conform to Part C/Section 1 of this NBCS.

NOTE — During construction, suitable measures shall be taken to ensure that masonry is not liable to damage or failure due to action of wind forces, back filling behind walls or temporary construction loads.

5.3 Load Dispersion

5.3.1 *General*

The angle of dispersion of vertical load on walls shall be taken as not more than 30° from the vertical.

5.3.2 *Arching Action*

Account may also be taken of the arching action of well-bonded masonry walls supported on lintels and beams, in accordance with established practice. Increased axial stresses in the masonry associated with arching action in this way, shall not exceed the permissible stresses given in **5.4**.

5.3.3 *Lintels*

Lintels that support masonry construction shall be designed to carry loads from masonry (allowing for arching and dispersion where applicable), and loads received from any other part of the structure. Length of bearing of lintel at each end shall not be less than 90 mm or one-tenth of the span, whichever is more, and area of the bearing shall be sufficient to ensure that stresses in the masonry (combination of wall stresses, stresses due to arching action and bearing stresses from the lintel) do not exceed the stresses permitted in **5.4** (*see* Annex C).

5.4 Permissible Stresses

5.4.1 *Permissible Compressive Stress*

Permissible compressive stress in masonry shall be based on value of basic compressive stress (f_b) as given in Table 9 and multiplying this value by factors known as stress reduction factor (k_s), area reduction factor (k_a) and shape modification factor (k_p) as detailed in **5.4.1.1** to **5.4.1.3**. Values of basic compressive stress given in Table 9 take into consideration crushing strength of masonry unit and grades of mortar, and hold good for values of slenderness ratio not exceeding 6, zero eccentricity and masonry unit having height to width ratio (as laid) equal to 0.75 or less.

Alternatively, basic compressive stress may be based on results of prism test given in Annex B on masonry made from masonry units and mortar to be actually used in a particular job.

Table 9 Basic Compressive Stresses for Masonry (After 28 days)

(*Clauses* 5.4.1, 5.4.5, 6.3.1 *and Table* 14)

Sl No.	Mortar Type (Ref to, Table 1)	Basic Compressive Stresses, in N/mm², Corresponding to Masonry Units of which Height to Width Ratio does not Exceed 0.75 and Crushing Strength, in N/mm², is not Less than

NOTES

1 The table is valid for slenderness ratio up to 6 and loading with zero eccentricity.

2 The values given for basic compressive stress are applicable only when the masonry is properly cured.

3 Linear interpolation is permissible for units having crushing strengths between those given in the table.

4 The permissible stress for random rubble masonry may be taken as 75 percent of the corresponding stress for coarsed walling of similar materials.

5 The strength of ashlar masonry (natural stone masonry of massive type with thin joints) is closely related to intrinsic strength of the stone and allowable working stress in excess of those given in the table may be allowed for such masonry at the discretion of the designer.

6 For calculation of basic compressive stress of stabilized soil block having thickness 100 mm or more, reference to specialist literature may be made.

7 If the work is inadequately supervised, strength should be reduced to three-fourth or less at the discretion of the designer.

5.4.1.1 *Stress reduction factor*

This factor, as given in Table 10, takes into consideration the slenderness ratio of the element and also the eccentricity of loading.

5.4.1.2 *Area reduction factor*

This factor takes into consideration smallness of the sectional area of the element and is applicable when sectional area of the element is less than 0.2 m^2. The factor $k_a = 0.7 + 1.5A$, A being the area of section, in m^2.

Table 10 Stress Reduction Factor for Slenderness Ratio and Eccentricity

(*Clause* 5.4.1.1, 9.2.2.3, 9.2.2.9 *and* 10.4.1)

Sl No.	Slenderness Ratio	Eccentricity of Loading Divided by the Thickness of the Member					
		0	1/24	1/12	1/6	1/4	1/3

xi)	26	0.45	0.40	0.35	0.25	—	—
xii)	27	0.43	0.38	0.33	0.22	—	—

NOTES

1 Linear interpolation between values is permitted.

2 Where in special cases the eccentricity of loading lies between 1/3 and 1/2 of the thickness of the member, the stress reduction factor should vary linearly between unity and 0.20 for slenderness ratio of 6 and 20, respectively.

3 Slenderness ratio of a member for sections within 1/8 of the height of the member above or below a lateral support may be taken to be 6.

5.4.1.3 *Shape modification factor*

This factor takes into consideration the shape of the unit, that is, height to width ratio (as laid) and is given in Table 11. This factor is applicable for units of crushing strength up to 15 N/mm^2.

5.4.1.4 *Increase in permissible compressive stresses allowed for eccentric vertical loads, lateral loads under certain conditions*

In members subjected to eccentric and/or lateral loads, increase in permissible compressive stress is allowed as follows:

a) When resultant eccentricity ratio exceeds 1/24 but does not exceed 1/6, 25 percent increase in permissible compressive stress is allowed in design; and

b) When resultant eccentricity ratio exceeds 1/6, 25 percent increase in permissible stress is allowed but the area of the section under tension shall be disregarded for computing the load carrying capacity of the member.

NOTE — When resultant eccentricity ratio of loading is 1/24 or less, compressive stress due to bending shall be ignored and only axial stress need to be computed for the purpose of design.

5.4.1.5 *Increase in permissible compressive stress for walls subjected to concentrated loads*

When a wall is subjected to a concentrated load (a load being taken to be concentrated when area of supporting wall equals or exceeds three times the bearing area), certain increase in permissible compressive stress may be allowed because of dispersal of the load. Since, according to the present state of art, there is diversity of views in regard to manner and extent of dispersal, design of walls subjected to concentrated loads may, therefore, be worked out as per the best judgment of the designer. Some guidelines in this regard are given in Annex C.

Table 11 Shape Modification Factor for Masonry Units

(*Clause* 5.4.1.3)

Sl No.	Height to Width Ratio of Units (as Laid)	Shape Modification Factor (k_p) For Units Having Crushing Strength in N/mm^2			
		Up to 5.0	7.5	10.0	15.0
(1)	(2)	(3)	(4)	(5)	(6)
i)	Up to 0.75	1.0	1.0	1.0	1.0
ii)	1.0	1.2	1.1	1.1	1.0
iii)	1.5	1.5	1.3	1.2	1.1
iv)	2.0 to 4.0	1.8	1.5	1.3	1.2

NOTE — Linear interpolation between values is permissible.

5.4.2 *Permissible Tensile Stress*

As a general rule, design of masonry shall be based on the assumption that masonry is not capable of taking any tension. However, in case of lateral loads normal to the plane of wall, which causes flexural tensile stress, as for example, panel, curtain partition and free standing walls, flexural tensile stresses as follows may be permitted in the design for masonry:

a) *Grade M1 or better mortar*:

1) 0.07 N/mm^2 for bending in the vertical direction where tension developed is normal to bed joints; and

2) 0.14 N/mm^2 for bending in the longitudinal direction where tension developed is parallel to bed joints, provided crushing strength of masonry units is not less than 10 N/mm^2.

b) *Grade M2 mortar*:

1) 0.05 N/mm^2 for bending in the vertical direction where tension developed is normal to bed joints; and

2) 0.10 N/mm^2 for bending in the longitudinal direction where tension developed is parallel to bed joints, provided crushing strength of masonry units is not less than 7.5 N/mm^2.

NOTES

1 No tensile stress is permitted in masonry in case of water-retaining structures in view of water in contact with masonry. Also no tensile stress is permitted in earth-retaining structures, in view of the possibility of presence of water at the back of such walls.

2 Allowable tensile stress in bending in the vertical direction may be increased to 0.1 N/mm^2 for M1 mortar and 0.07 N/mm^2 for M2 mortar in case of boundary walls/compound at the discretion of the designer, since there is not much risk to life and property in the event of failure of such walls.

5.4.3 *Permissible Shear Stress*

In case of walls built in mortar not leaner than Grade M1 (*see* Table 1) and resisting horizontal forces in the plane of the wall, permissible shear stress calculated on the area of bed joints, shall not exceed the value obtained by the formula given below, subject to a maximum of 0.5 N/mm^2:

$$f_s = 0.1 + f_d/6$$

where

f_s = permissible shear stress, in N/mm^2; and

f_d = compressive stress due to dead loads, in N/mm^2.

5.4.4 If there is tension in any part of a section of masonry, the area under tension shall be ignored while working out shear stress on the section.

5.4.5 *Specified Compressive Strength*

The specified compressive strength $\boldsymbol{f}_{\mathbf{m}}$ (in MPa) shall be determined by:

a) testing prism specimens as per Annex B; and

b) the expression:

$$f_{\mathrm{m}} = 0.433 f_{\mathrm{b}}^{0.64} f_{\mathrm{m0}}^{0.36}$$

where

f_{b} = compressive strength (in MPa) of clay brick as per Table 9; and

f_{m0} = compressive strength of mortar as per **5.4.1.**

c) as per **5.4.1**.

5.4.6 *Elastic Modulus*

Elastic modulus, E_{m} of masonry shall be determined by testing masonry prisms as per **5.4.5(a)**; the chord modulus of elasticity shall be taken as the slope of the chord between 0.05 Max. and 0.33 of the Max. compressive strength of each prism:

The expressions:

$$E_{\mathrm{m}} = \begin{cases} 550 f_{\mathrm{m}} & \text{clay brick masonry} \\ 850 f_{\mathrm{m}} & \text{concrete block masonry} \end{cases}$$

5.4.7 *Shear Modulus*

The shear modulus, G_{m} shall be determined by:

$$G_{\mathrm{m}} = 0.2 E_{\mathrm{m}}$$

5.5 Design Thickness/Cross-Section

5.5.1 *Walls and Columns Subjected to Vertical Loads*

Walls and columns bearing vertical loads shall be designed on the basis of permissible compressive stress. Design consists in determining thickness in case of walls and section in case of columns in relation to strength of masonry units and grade of mortar to be used, taking into consideration various factors, such as slenderness ratio, eccentricity, area of section, workmanship, quality of supervision, etc, subject further to provisions of **5.5.1.1** to **5.5.1.4**.

5.5.1.1 *Solid walls*

Thickness used for design calculation shall be the actual thickness of masonry computed as the sum of the average dimensions of the masonry units specified in the relevant standard, together with the specified joint thickness. In masonry with raked joints, thickness shall be reduced by the depth of raking of joints for plastering/pointing.

5.5.1.2 *Cavity walls*

a) Thickness of each leaf of a cavity wall shall not be less than 75 mm;

b) Where the outer leaf is half masonry unit in thickness, the uninterrupted height and length of this leaf shall be limited so as to avoid undue loosening of ties due to differential movements between the two leaves. The outer leaf shall, therefore, be supported at least at every third storey or at every 10 m of height, whichever is less and at every 10 m or less along the length;

c) Where the load is carried by both leaves of a wall of a cavity construction, the permissible stress shall be based on the slenderness ratio derived from the effective thickness of the wall as given in **4.5.4** or **4.5.5**. The eccentricity of the load shall be considered with respect to the centre of gravity of the cross-section of the wall; and

d) Where the load is carried by one leaf only, the permissible stress shall be the greater of values calculated by the following two alternative methods:

   1) The slenderness ratio is based on the effective thickness of the cavity wall as a whole as given in **4.5.4** or **4.5.5** and on the eccentricity of the load with respect to the centre of gravity of the cross-section of the whole wall (both leaves) (This is the same method as where the load is carried by both the leaves but the eccentricity will be more when the load is carried by one leaf only); and

   2) The slenderness ratio is based on the effective thickness of the loaded leaf only using **4.5.1** and **4.5.2**, and the eccentricity of the load will also be with respect to the centre of gravity of the loaded leaf only.

In either alternative, only the actual thickness of the load bearing leaf shall be used in arriving at the cross-sectional area resisting the load (*see* **5.5.1.1**).

5.5.1.3 *Faced wall*

The permissible load per length of wall shall be taken as the product of the total thickness of the wall and the permissible stress in the weaker of the two materials. The permissible stress shall be found by using the total thickness of the wall when calculating the slenderness ratio.

5.5.1.4 *Veneered wall*

The facing (veneer) shall be entirely ignored in calculations of strength and stability. For the purpose of determining the permissible stress in the backing, the slenderness ratio shall be based on the thickness of the backing alone.

5.5.2 *Walls and Columns Mainly Subjected to Lateral Loads*

5.5.2.1 *Free standing walls*

a) Free standing walls, subjected to wind pressure or seismic forces shall be designed on the basis of permissible tensile stress in masonry or stability as in **4.2.2.4**. However, in seismic Zones II, free-standing walls may be apportioned without making any design calculations with the help of Table 12 provided the mortar used is of grade not leaner than M1; and

b) If there is a horizontal damp-proof course near the base of the wall, that is, not capable of developing tension vertically, the minimum wall thickness should be the greater of that calculated from either:

   1) the appropriate height to thickness ratio given in Table 12 reduced by 25 percent, reckoning the height from the level of the damp-proof course; or

   2) the appropriate height to thickness ratio given in Table 12 reckoning the height from the lower level at which the wall is restrained laterally.

Table 12 Height to Thickness Ratio of Free Standing Walls Related to Wind Speed

[*Clause* 5.5.2.1(a) *and* (b)]

Sl No.	Design Wind Pressure N/mm^2	Height to Thickness Ratio
(1)	(2)	(3)
i)	Up to 285	10
ii)	575	7
iii)	860	5
iv)	1 150	4

NOTES

1 For intermediate values, linear interpolation is permissible.

2 Height is to be reckoned from 150 mm below ground level or top of footing/foundation block, whichever is higher, and up to the top edge of the wall.

3 The thickness should be measured including the thickness of the plaster.

5.5.2.2 *Retaining walls*

Normally masonry of retaining walls shall be designed on the basis of zero-tension, and permissible compressive stress. However, in case of retaining walls for supporting horizontal thrust from dry materials, retaining walls may be designed on the basis of permissible tensile stress at the discretion of the designers.

5.5.3 *Walls and Columns Subjected to Vertical as well as Lateral Loads*

For walls and columns, stress worked out separately for vertical loads as in **5.5.1** and lateral loads as in **5.5.2** shall be combined and elements designed on the basis of permissible stress.

5.5.4 *Walls Subjected to In-Plane Bending and Vertical Loads* (*Shear Walls*)

Walls subjected to in-plane bending and vertical loads, that is, shear walls shall be designed on the basis of no tension with permissible shear stress and permissible compressive stress.

5.5.5 *Non-Load Bearing Walls*

Non-load bearing walls, such as panel walls, curtain walls and partition walls which are mainly subjected to lateral loads, according to present state of art, are not capable of precise design and only approximate methods based on some tests are available. Guidelines for approximate design of these walls are given in Annex D.

6 GENERAL REQUIREMENTS

6.1 Methods of Construction

6.1.1 *General*

Construction of the following types of load bearing and non-load bearing masonry walls shall be carried out in accordance with good practice [C-4(4)]:

a) brickwork;

b) stone masonry;

c) hollow concrete block masonry;

d) gypsum partition blocks;

e) autoclaved cellular concrete block masonry; and

f) lightweight concrete block masonry.

6.1.2 *Construction of Buildings in Seismic Zones*

Special features of construction for earthquake resistant masonry buildings in zones III and above shall be applicable according to **8**.

6.2 Minimum Thickness of Walls from Consideration Other than Structural

Thickness of walls determined from consideration of strength and stability may not always be adequate in respect of other requirements, such as resistance to fire, thermal insulation, sound insulation and resistance to damp penetration for which reference may be made to the appropriate Parts/Sections of the NBCS, and thickness suitably increased, where found necessary.

6.3 Workmanship

6.3.1 *General*

Workmanship has considerable effect on strength of masonry and bad workmanship may reduce the strength of brick masonry to as low as half the intended strength. The basic compressive stress values for masonry as given in Table 9 holds good for commercially obtainable standards of workmanship with reasonable degree of supervision.

6.3.2 *Bedding of Masonry Units*

Masonry units shall be laid on a full bed of mortar with frog, if any, upward such that cross-joints and wall joints are completely filled with mortar. Masonry units which are moved after initial placement shall be re-laid in fresh mortar, discarding the disturbed mortar.

6.3.3 *Bond*

Cross-joints in any course of one brick thick masonry wall shall be not less than one-fourth of a masonry unit in horizontal direction from the cross-joints in the course below. In masonry walls more than one brick in thickness, bonding through the thickness of wall shall be provided by either header units or by other equivalent means in accordance with good practice [C-4(5)].

6.3.4 *Verticality and Alignment*

All masonry shall be built true and plumb within the tolerances prescribed below; care shall be taken to keep the perpends properly aligned:

a) deviation from vertical within a storey shall not exceed 6 mm per 3 m height;

b) deviation in verticality in total height of any wall of a building more than one storey in height shall not exceed 12.5 mm.;

c) deviation from position shown on plan of any brickwork shall not exceed 12.5 mm;

d) relative displacement between load bearing walls in adjacent storeys intended to be in vertical alignment shall not exceed 6 mm;

e) deviation of bed-joint from horizontal in a length of 12 m shall not exceed 6 mm subject to a maximum deviation of 12 mm; and

f) deviation from the specified thickness of bed joints, cross-joints and perpends shall not exceed one-fifth of the specified thickness.

NOTE — These tolerances have been specified from the point of view of their effect on the strength of masonry. The permissible stress recommended in 5.3 may be considered applicable only, if these tolerances are adhered to.

6.4 Joints to Control Deformation and Cracking

Special provision shall be made to control or isolate thermal and other movements so that damage to the fabric of the building is avoided and its structural sufficiency preserved. Design and installation of joints shall be done according to the appropriate recommendations in accordance with good practice [C-4(6)].

6.5 Chases, Recesses and Holes

6.5.1 Chases, recesses and holes are permissible in masonry only if these do not impair strength and stability of the structure.

6.5.2 In masonry, designed by structural analysis, all chases, recesses and holes shall be considered in structural design and detailed in building plans.

6.5.3 When chases, recesses and holes have not been considered in structural design and are not shown in drawings, these may be provided, subject to the constraints and precautions specified in 6.5.3.1 to 6.5.3.10.

6.5.3.1 As far as possible, services should be planned with the help of vertical chases and use of horizontal chases should be avoided.

6.5.3.2 For load bearing walls, depth of vertical and horizontal chases shall not exceed one-third and one-sixth of the wall thickness, respectively.

6.5.3.3 Vertical chases shall not be closer than 2 m in any stretch of wall and shall not be located within 345 mm of an opening or within 230 mm of a cross wall that serves as a stiffening wall for stability. Width of a vertical chase shall not exceed thickness of wall in which it occurs.

6.5.3.4 When unavoidable horizontal chases of width not exceeding 60 mm in a wall having slenderness ratio not exceeding 15 may be provided. These shall be located in the upper or lower middle third height of wall at a distance not less than 600 mm from a lateral support. No horizontal chase shall exceed 1 m in length and there shall not be more than 2 chases in any one wall. Horizontal chases shall have minimum mutual separation distance of 500 mm. Sum of lengths of all chases and recesses in any horizontal plane shall not exceed one-fourth the length of the wall.

6.5.3.5 Holes for supporting put-logs of scaffolding shall be kept away from bearings of beams, lintels, and other concentrated loads. If unavoidable, stresses in the affected area shall be checked to ensure that these are within safe limits.

6.5.3.6 No chase, recess or hole shall be provided in any stretch of a masonry wall, the length of which is less than four times the thickness of wall, except when found safe by structural analysis.

6.5.3.7 Masonry directly above a recess or a hole, if wider than 300 mm, shall be supported on a lintel. No lintel, however, is necessary in case of a circular recess or hole exceeding 300 mm in diameter provided upper half of the recess or hole is built as a semi-circular arch of adequate thickness and there is an adequate length of masonry on the sides of openings to resist the horizontal thrust.

6.5.3.8 As far as possible, chases, recesses and holes in masonry should be left (inserting sleeves, where necessary) at the time of construction of masonry so as to obviate subsequent cutting. If cutting is unavoidable, it should be done without damage to the surrounding or residual masonry. It is desirable to use such tools for cutting which depend upon rotary and not on heavy impact for cutting action.

6.5.3.9 No chase, recess or hole shall be provided in half-brick load bearing wall, excepting the minimum number of holes needed for scaffolding.

6.5.3.10 Chases, recesses or holes shall not be cut into walls made of hollow or perforated units, after the units have been incorporated in masonry.

6.6 Corbelling

6.6.1 Where corbelling is required for the support of some structural element, maximum projection of masonry unit should not exceed one-half of the height of the unit or one-half of the built-in part of the unit and the maximum horizontal projection of the corbel should not exceed one-third of the wall thickness.

6.6.2 The load per unit length on a corbel shall not be greater than half of the load per unit length on the wall above the corbel. The load on the wall above the corbel, together with four times the load on the corbel, shall not cause the average stress in the supporting wall or leaf to exceed the permissible stresses given in **5.4**.

6.6.3 It is preferable to adopt header courses in the corbelled portion of masonry from considerations of economy and stability.

7 REINFORCED BRICK AND REINFORCED BRICK CONCRETE FLOORS AND ROOFS

The construction and design of reinforced brick and reinforced brick concrete floors and roof shall be in accordance with good practices [C-4(7)].

8 SPECIAL CONSIDERATION FROM EARTHQUAKE POINT OF VIEW

The design and construction of masonry buildings shall be governed by provisions of **4**, except as modified by the provisions of this section for those elements participating in lateral force resistance. The design and construction for earthquake resistant masonry buildings are given in **8**, **9** and **10**. The earthquake resistant design and detailing of masonry buildings having the following structural systems:

a) Masonry Walls with Prescriptive Bands (MWB);

b) Masonry Walls with Prescriptive Bands and Vertical Reinforcements (MWBR);

c) Confined Masonry Walls (CMW) (*see* **9**); and

d) Reinforced Masonry Walls (RMW) (*see* **10**).

Buildings with MWB and MWBR systems shall not be of height more than 15 m subject to a maximum of four storeys, measured from the base of the buildings to the roof slab or ridge level.

8.1 For the purpose of 8 and 9, the following definitions shall apply in addition to those given in 2.

8.1.1 *Separation Section*

The gap of specified width between adjacent buildings or parts of the same building either left uncovered or covered suitably to permit movement to avoid pounding due to earthquake.

8.1.1.1 *Crumple section*

The separation gap filled with appropriate material that crumples or factures in the event of an earthquake.

8.1.2 *Centre of Rigidity*

The point at the floor level of a structure where application of lateral force in a particular principal direction produces equal deflections of the floor components along that direction.

8.1.3 *Load Bearing Wall*

A wall designed to resist axial force, shear force in its own plane and bending moment about its major axis.

8.1.4 *Box System*

A building made of masonry load bearing walls and horizontal floors.

8.1.5 *Band*

A wooden (in low strength masonry buildings), reinforced concrete or reinforced brick runner provided in the walls to tie them together and to impart horizontal bending strength in them.

8.1.6 *Earthquake Zone*

The earthquake zones as classified in **5** of Part C/Section 1 of this NBCS.

8.1.7 *Design Horizontal Acceleration Coefficient*

The horizontal acceleration coefficient A_h computed considering the importance factor and soil-foundation system as specified in **5** of Part C/Section 1 of this NBCS.

8.1.8 *Concrete Strength*

The 28-day compressive strength (in MPa) of concrete cubes of 150 mm size.

8.1.9 *Cross-Sectional Area of Masonry Unit*

The net cross-sectional area of a masonry unit shall be taken as the gross cross-sectional area minus the area of cellular space (if any). Gross cross-sectional area of cored units shall be determined to the outside of the coring, but cross-sectional area of grooves (if any) shall not be deducted from the gross cross-sectional area to obtain the net cross-sectional area.

8.1.10 *Grout*

A mixture of cement, sand, and water of pourable consistency for filling small voids.

8.1.11 *Grouted Masonry*

Masonry in which the masonry units with holes are filled with a mixture of cement and sand.

8.1.11.1 *Grouted hollow-unit masonry*

A form of grouted masonry construction in which certain designated cells of hollow units are continuously filled with grout.

8.1.11.2 *Grouted multi-wythe masonry*

A form of grouted masonry construction in which the space between the wythes is solidly or periodically filled with grout.

8.1.12 *Joint Reinforcement*

A prefabricated reinforcement in the form of lattice truss which has been hot dip galvanized after fabrication and is to be laid in the mortar bed joint.

8.1.13 Pier

An isolated vertical member whose horizontal dimension measured at right angles to its thickness is not less than 4 times its thickness and whose height is less than 5 times its length.

8.1.14 *Prism*

An assemblage of masonry units bonded by mortar with or without grout used as a test specimen for determining properties of masonry.

8.1.15 *Reinforced Masonry*

Masonry which is reinforced (as specified in 2) and grouted (if necessary) so that the two materials act together in resisting forces.

8.1.16 *Grouted Cavity Reinforced Masonry*

Masonry with two parallel single-leaf walls spaced at least 50 mm apart, and effectively tied together with wall ties. The intervening cavity contains steel reinforcement and is filled with infill concrete so as to result in common action with masonry under load.

8.1.17 *Pocket type Reinforced Masonry*

Masonry reinforced primarily to resist lateral loading where the main reinforcement is concentrated in vertical pockets formed in the tension face of the masonry and is surrounded by in situ concrete.

8.1.18 *Quetta Bond Reinforced Masonry*

Masonry that is at least one and half units thick, in which vertical pockets containing reinforcement and mortar or concrete infill occur at intervals along its length.

8.1.19 *Specified Compressive Strength of Masonry*

Minimum compressive strength (in MPa) is force per unit of net cross-section area, which is required of the masonry used in construction and upon which the design is based.

8.1.20 *Wall Tie*

A metal fastener, which connects wythes of masonry to each other or to other materials.

8.1.21 *Wythe*

A continuous vertical layer of masonry wall of one unit in thickness.

NOTE — For low strength masonry buildings, wooden runners may also be used as runner.

8.2 General Principles

The general principles given in 8.2.1 to 8.2.9 shall be observed in construction of earthquake resistant buildings.

8.2.1 *Lightness*

Since the earthquake force is a function of mass, the weight of the building shall be as minimum as possible, consistent with structural safety and functional requirements. Roofs and upper storeys of buildings, in particular, should be designed as light as possible.

8.2.2 *Continuity of Construction*

8.2.2.1 As far as possible, the parts of the building should be tied together in such a manner that the building acts as one unit.

8.2.2.2 For parts of buildings between separation or crumple sections to expansion joints, floor slabs shall be continuous throughout as far as possible. Concrete slabs shall be rigidly connected or integrally cast with the support beams.

8.2.2.3 Additions to the structures shall be accompanied by the provision of separation or crumple sections between the new and the existing structures as far as possible, unless positive measures are taken to establish continuity between the existing and the new construction.

8.2.2.4 Alteration to the building structure shall be done by maintaining its structural stability by ensuring proper load path.

8.2.3 *Projecting and Suspended Parts*

8.2.3.1 Projecting parts shall be avoided as far as possible. If the projecting parts cannot be avoided, they shall be properly reinforced and firmly tied to the main structure, and their design shall be in accordance with **5** of Part C/Section 1 of this NBCS.

8.2.3.2 Ceiling plaster shall preferably be avoided. When it is unavoidable, the plaster shall be as thin as possible.

8.2.3.3 Suspended ceiling shall be avoided as far as possible. Where provided they shall be light, adequately framed and secured to which electrical fixtures shall be fully secured.

8.2.4 *Building Configuration*

8.2.4.1 Masonry buildings shall have walls placed uniformly along the two principal plan directions. Buildings with the irregularities listed in **5** of Part C/Section 1 of this NBCS perform poorly during earthquake shaking, and should be avoided. When these irregularities appear in a building, the guidance given in **5** of Part C/Section 1 of this NBCS for the respective irregularity shall be followed. In order to minimize torsion and stress concentration, provisions given in 8.2.4.2 to 8.2.4.4 should be complied with as relevant.

8.2.4.2 The building should have a simple rectangular plan and be symmetrical both with respect to mass and rigidity so that the centre of mass and rigidity of the building coincide with each other in which case no separation sections other than expansion joints are necessary. For provision of expansion joints reference may be made to [C-4(6)].

8.2.4.3 If symmetry of the structure is not possible in plan, elevation or mass, provision shall be made for torsional and other effects due to earthquake forces in the structural design or the parts of different rigidities may be separated through crumple sections. The length of such building between separation sections shall not preferably exceed three times the width.

NOTE — As an alternative to separation section to reduce torsional moments, the centre of rigidity of the building may be brought close or coincident to the centre of mass by adjusting the locations and/or sizes of columns and walls.

8.2.4.4 Buildings having plans with shapes like L, T, E and Y shall preferably be separated into rectangular parts by providing separation sections at appropriate places. Typical examples are shown in Fig. 15.

NOTES

1 The buildings with small lengths of projections forming L, T, E or Y shapes need not be provided with separation section. In each cases the length of the projection may not exceed 15 percent to 20 percent of the total dimension of the building in the direction of the projection (*see* Fig. 16).

2 For buildings with minor asymmetry in plan and elevation, separation sections may be omitted.

8.2.5 *Strength in Various Directions*

The structure shall be designed to have adequate strength against earthquake effects along both the horizontal axes. The design shall also be safe considering the reversible nature of earthquake forces.

8.2.6 *Foundations*

The structure shall not be founded on such soils which shall subside or liquefy during an earthquake, resulting in large differential settlements (*see also* **8.3.3.3**).

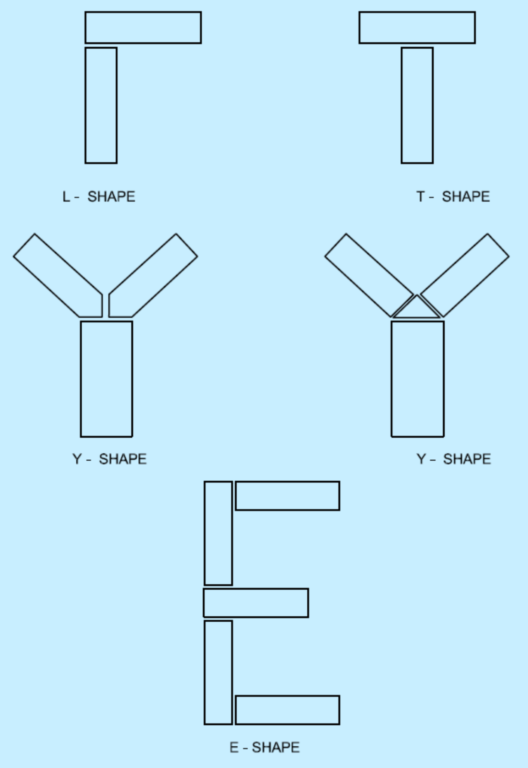

FIG. 15 TYPICAL SHAPES OF BUILDING WITH SEPARATION SECTIONS

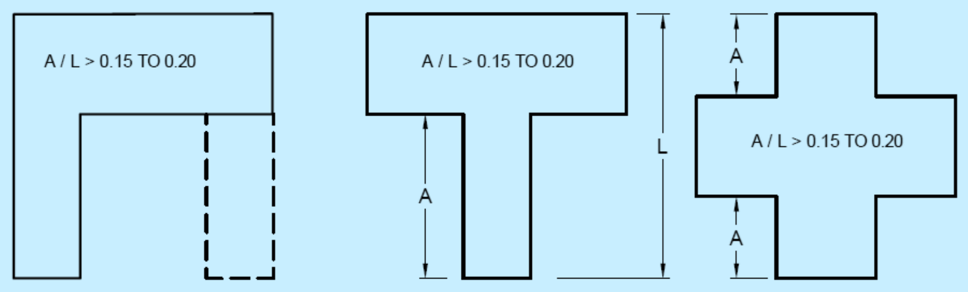

FIG. 16 (A) PLAN IRREGULARITIES

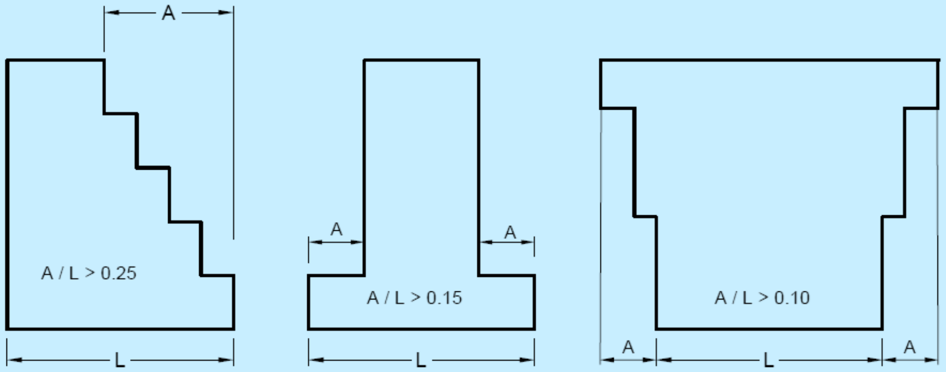

FIG. 16(B) VERTICAL IRREGULARITIES

FIG. 16 PLAN AND VERTICAL IRREGULARITIES

8.2.7 *Ductility*

The main structural elements and their connection shall be designed to have a ductile failure. This shall enable the structure to absorb energy during earthquakes to avoid sudden collapse of the structure. Providing reinforcing steel in masonry at critical sections, as specified in this Section shall not only increase strength and stability but also ductility. The details for achieving ductility in reinforced concrete structures is given in Part C 'Structural Design, Section 5 Structural Concrete' of this NBCS.

8.2.8 *Damage to Non-Structural Parts*

Suitable details shall be worked out to connect the non-structural parts with the structural framing so that the deformation of the structural frame leads to minimum damage of the non-structural elements.

8.2.9 *Fire Safety*

Fire frequently follows an earthquake and therefore, buildings shall be constructed to make them fire resistant in accordance with the provisions of Part F 'Fire and Life Safety' of this NBCS.

8.3 Special Construction Features

8.3.1 *Separation of Adjoining Structures*

8.3.1.1 Separation of adjoining structures or parts of the same structure is required for structures having different total heights or storey heights and different dynamic characteristics. This is to avoid collision during an earthquake.

8.3.1.2 Minimum width of separation gaps as mentioned in **8.3.1.1**, shall be as specified in Table 13. The design seismic coefficient to be used shall be in accordance with **5** of Part C/Section 1 of this NBCS.

8.3.1.3 Where separation is necessary, a complete separation of the parts shall be made except below the plinth level. The plinth beams, foundation beams and footings may be continuous. Where separation sections are provided in a long building, they shall take care of movement owing to temperature changes also.

8.3.2 *Separation or Crumple Section*

8.3.2.1 In case of framed construction, members shall be duplicated on either side of the separation or crumple section. As an alternative, in certain cases, such duplication may not be provided, if the portions on either side can act as cantilevers to take the weight of the building and other relevant loads.

8.3.2.2 Typical details of separation and crumple sections are shown in Fig. 17. For other types of joint details, reference may be made to [C-4(5)].

8.3.3 *Foundations*

8.3.3.1 For the design of foundations, the provisions of Part C/Section 1 and Section 2 of this NBCS shall generally be followed.

8.3.3.2 The subgrade below the entire area of the building shall preferably be of the same type of the soil. Wherever this is not possible, a suitably located separation or crumple section shall be provided.

8.3.3.3 Loose fine sand, soft silt and expansive clays should be avoided. If unavoidable, the building shall rest either on a rigid raft foundation or on piles taken to a firm stratum. However, for light constructions the following measures may be taken to improve the soil on which the foundation of the building may rest:

a) sand piling; and

b) soil stabilization.

8.3.3.4 *Isolated footings for columns*

All the individual footings or pile caps where used in Type III Soft soils, shall be connected by reinforced concrete ties at least in two directions approximately at right angles to each other. For buildings with no basement, the ties may be placed at or below the plinth level and for buildings with basement they may be placed at the level of basement floor. They shall need to be designed to carry the load of the panel walls also.

NOTE — The ties may not be necessary where structural floor connects the columns at or below the plinth level.

8.3.3.4.1 Where ties are used, their sections shall be designed to carry in tension as well as in compression, an axial load not less than the earthquake force in the direction the tie acting on the heavier of the columns connected, but the sections shall not be less than 200 mm × 200 mm with M20 concrete reinforced with 4 bars of 12 mm diameter plain mild steel bars or 10 mm diameter high strength deformed bars, one at each corner, bound by 8 mm diameter stirrups not more than 150 mm apart.

NOTE — In working out the buckling strength of ties, the lateral support provided by the soil may be taken into account. Calculations show that for such buried ties, lateral buckling is not a problem and the full section of the tie may be taken effective as a short column.

8.3.3.4.2 In the case of reinforced concrete slab, the thickness shall not be less than 1/50th of the clear distance between the footings, but not less than 100 mm in any case. It shall be reinforced with not less than 0.15 percent mild steel bars or 0.12 percent high strength deformed bars in each direction placed symmetrically at top and bottom.

8.3.4 *Roofs and Floors*

8.3.4.1 Flat roof or floor shall not preferably be made of tiles of ordinary bricks supported on steel, timber or reinforced concrete joists, nor they shall be of a type which in the event of an earthquake is likely to be loosened and parts or all of which may fall. If this type of construction cannot be avoided, the joists should be blocked at ends and bridged at intervals such that their spacing is not altered during an earthquake.

8.3.4.1.1 For pitched roofs, corrugated iron or asbestos sheets shall be used in preference to country, Allahabad or Mangalore tiles or other loose roofing units. All roofing materials shall be properly tied to the supporting members. Heavy roofing materials shall generally be avoided.

8.3.4.2 *Pent roofs*

8.3.4.2.1 All roof trusses shall be supported on reinforced concrete or reinforced brick band (*see* **8.5**). The holding down bolts shall have adequate size and length as required for earthquake forces in accordance with **5** of Part C/Section 1 of this NBCS.

Where a trussed roof adjoins a masonry gable, the ends of the purlins shall be carried on and secured to a plate or bearer which shall be adequately bolted to reinforced concrete or reinforced brick band at the top of gable end masonry.

NOTE — Hipped roof in general have shown better structural behaviour during earthquakes than gable ended roofs.

8.3.4.2.2 At tie level all the trusses and the gable end shall be provided with diagonal braces in plan so as to transmit the lateral shear due to earthquake force to the gable walls acting as shear walls at the ends as specified in **8.5**.

8.3.4.3 *Jack arches*

Jack arched roofs or floors, where used shall be provided with mild steel ties in all spans along with diagonal braces in plan to ensure diaphragms actions.

8.3.5 *Staircases*

8.3.5.1 The inter-connection of the stairs with the adjacent floors should be appropriately treated by providing sliding joints at the stairs to eliminate their bracing effect on the floors. Large stair halls shall preferably be separated from the rest of the building by means of separation or crumple sections.

8.3.5.2 Three types of stair construction may be adopted as described below:

a) *Separated staircases* — One end of the staircase rests on a wall and the other end is carried by columns and beams which have no connection with the floors. The gap at the vertical joints between the floor and the staircase may be covered either with a tread plate attached to one side of the joint and sliding on the other side, or covered with some appropriate material which could crumple or fracture during an earthquake without causing structural damage. The supporting members, columns or walls, are isolated from the surrounding floors by means of separation or crumple sections. A typical example is shown in Fig. 18;

b) *Built-in staircase* — When stairs are built monolithically with floors, they can be protected against damage by providing rigid walls at the stair opening. An arrangement, in which the staircase is enclosed by two walls, is given in Fig. 19. In such cases, the joints, as mentioned in respect of separated staircases, shall not be necessary;

The two walls mentioned above, enclosing the staircase, shall extend through the entire height of the stairs and to the building foundations; and

c) *Staircases with sliding joints* — In case it is not possible to provide rigid walls around stair openings for built-in staircase or to adopt the separated staircases, the staircases shall have sliding joints so that they shall not act as diagonal bracing.

8.3.6 *Framing of Thin Load Bearing Walls* (*see* Fig. 20)

Load bearing walls can be made thinner than 200 mm say 150 mm inclusive of plastering on both sides. Reinforced concrete framing columns and collar beams shall be necessary to be constructed to have full bond with the walls. Columns are to be located at all corners and junctions of walls and spaced not more than 1.5 m apart but so located as to frame up the doors and windows. The horizontal bands or ring beams are located at all floors, roof as well as lintel levels of the openings. The sequence of construction between walls and columns shall be first to build the wall up to 4 to 6 courses height leaving toothed gaps (tooth projection being about 40 mm only) for the columns and second to pour M20 (1 : 1½ : 3) concrete to fill the columns against the walls using wood forms only on two sides. The columns steel should be accurately held in position all along. The band concrete should be cast on the wall masonry directly so as to develop full bond with it.

Such construction may be limited to only two storeys maximum in view of its vertical load carrying capacity. The horizontal length of walls between cross walls shall be restricted to 7 m and the storey height to 3 m.

8.3.7 *Reinforcing Details for Hollow Block Masonry*

The following details may be followed in placing the horizontal and vertical steel in hollow block masonry using cement-sand or cement-concrete blocks.

8.3.7.1 *Horizontal band*

U-shaped blocks may be used for construction of horizontal bands at various levels of the storeys as shown in Fig. 21, where the amount of horizontal reinforcement shall be taken 25 percent more than that given in Table 18 and provided by using four bars and 6 mm diameter stirrups. Other continuity details shall be followed, as shown in Fig. 28.

NOTES

1 Detailing of steel around the window openings will be same as for door openings with additional 75 mm band at sill level.

2 Figures are for just explanation purposes and the same shall not be used as design guide.

8.3.7.2 *Vertical reinforcement*

Bars, as specified in Table 19 shall be located inside the cavities of the hollow blocks, one bar in each cavity (*see* Fig. 29). Where more than one bar is planned these can be located in two or three consecutive cavities. The cavities containing bars are to be filled by using micro-concrete 1 : 2 : 3 or cement coarse sand mortar 1 : 3, and properly rodded for compaction. The vertical bars should be spliced by welding or overlapping for developing full tensile strength. For proper bonding, the overlapped bars should be tied together by winding the binding wire over the lapped length. To reduce the number of overlaps, the blocks may be made U-shaped as shown in Fig. 29 which shall avoid lifting and threading of bars into the hollows.

8.4 DESIGN CONSIDERATIONS

8.4.1 *Design Philosophy*

The design approach adopted for masonry buildings is the working stress method at serviceability loads, with structural materials assumed to behave in linear elastic manner. Safety is ensured by restricting stresses in material induced by design loads imposed on the structure as per the load combinations specified in **5** of Part C/Section 1 of this NBCS.

8.4.1.1 *Working stress method*

In the working stress method of design of members, permissible stresses given in Table 14 shall govern the earthquake resistant design of members of the masonry building systems specified in this section.

	Axial	Axial and Flexural	Axial and Flexural	
(1)	(2)	(3)	(4)	(5)
				b) with web reinforcement: $f_v = 0.25\sqrt{f_m} \le 0.75\text{MPa}$ For walls, shall be as per **5.4.3**

8.4.2 Bands and Vertical Elements

Masonry buildings, other than those with reinforced masonry walls and confined masonry walls, shall be provided with horizontal bands and vertical reinforcing elements:

a) the horizontal bands shall run along the full perimeter of the external and internal walls, within the full thickness of the walls; and

b) the vertical reinforcing elements shall pass through vertically at all corners and adjoining all openings (door, window, and ventilator).

8.4.2.1 *Types*

Five types of bands are admissible, namely:

a) Gable band (when masonry buildings have gable walls);

b) Roof band;

c) Lintel band;

d) Sill band; and

e) Plinth band.

8.4.2.2 *Geometry*

The width of RC band shall be same as the thickness of the wall. Wall thickness shall be at least 200 mm. A clear cover of 20 mm shall be maintained for the reinforcement.

The vertical thickness of RC Band shall be at least:

a) 75 mm, where two longitudinal bars are specified, one on each face; and

b) 150 mm, where four bars are specified, one at each corner.

8.4.2.3 *Ductile detailing*

The bands shall be made of reinforced concrete of grade not leaner than M25 or reinforced brickwork in cement mortar not leaner than 1 : 3. In coastal areas, the filling mortar with water proofing admixture shall be used.

8.4.3 *Floor Slabs*

The roof and floor slabs in MWBs, MWBR, CMBs and RMBs shall be designed as beam supported slabs as per the provisions of Part C/Section 5 of this NBCS.

8.4.4 *Building Structure Type*

Masonry buildings shall be categorized into four types (Table 15), namely Types B, C, D and E, based on the earthquake and the category of the building and the importance of building I, where I is importance factor applicable to the building. Type E buildings shall not be more than 3 storeys tall.

ii)	1.5	C	D	*E*	*E*

8.4.4.1 *Slenderness of walls*

The masonry walls shall meet the slenderness limit specified in Table 16.

Table 16 Allowable Effective Height to Effective Thickness Ratios of Unreinforced Masonry Walls

(*Clause* 8.4.4.1)

Sl No.	**Wall**	**Building Structure Type**			
		B	C	D	E
(1)	(2)	(3)	(4)	(5)	(6)
i)	MWB and MWBR	15	15	12	12
ii)	CMW	15	15	15	15
iii)	RMW	15	15	15	15
iv)	URM parapet walls	12	12	6	6

8.4.5 *Footings*

Strip footings under load bearing walls shall be designed as per the provisions of [C-4(8)] in conjunction with Part C/Section 1 of this NBCS.

8.5 Masonry Walls with Prescriptive Bands (MWB), and Masonry Walls with Prescriptive Bands and Vertical Reinforcement (MWBR)

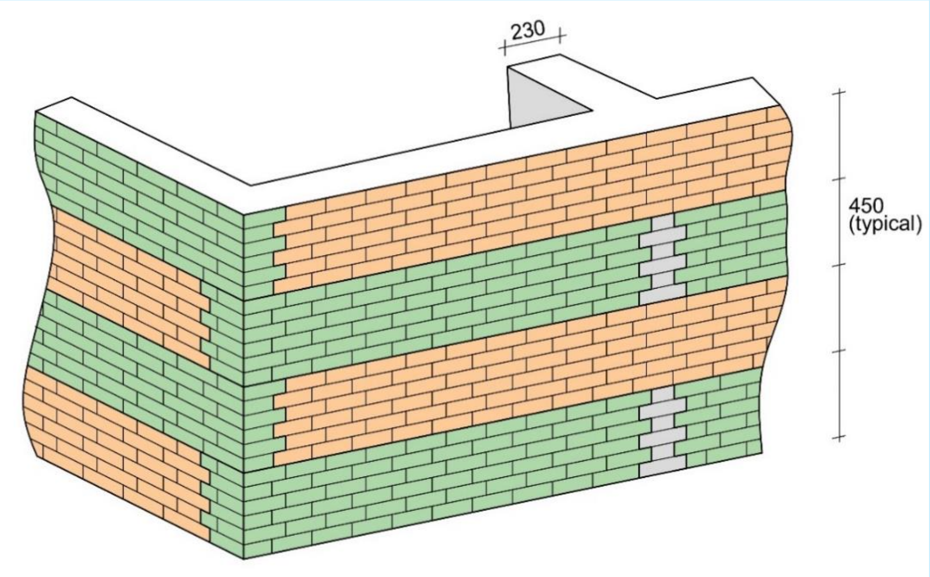
8.5.1 *Masonry Walls*

8.5.1.1 The bearing walls in both directions shall be straight and symmetrical in plan.

8.5.1.2 The wall panels formed between cross walls and floors, or roof shall be checked for their strength in bending as a plate or as a vertical strip subjected to the earthquake force acting on its own mass. This check need not be complied with in walls of 200 mm or larger thickness and of storey height less than 3.5 m

8.5.1.3 *Masonry bond*

For achieving full strength of masonry, the usual bonds specified for masonry should be followed so that the vertical joints are broken properly from course to course. To obtain full bond between perpendicular walls, it is necessary to make a slopping (stepped) joint by making the corners first to a height of 600 mm and then building the wall in between them. Otherwise, the toothed joint should be made in both the walls alternatively in lifts of about 450 mm (Fig. 23).



All dimensions in millimetres.

FIG. 23 ALTERNATING TOOTHED JOINTS IN WALLS AT CORNER AND T-JUNCTION

8.5.2 *Openings in Bearing Walls*

8.5.2.1 Door and window openings reduce the lateral load resistance of walls, and hence, should preferably be small and more centrally located in the wall panels. The guidelines on the size and position of opening are given in Table 17 and Fig. 24.

8.5.2.2 Openings in any storey shall have their top at the same level to accommodate a continuous band over them, including the lintels throughout the building. In addition, openings in different storeys in a masonry wall shall be vertically aligned, and not staggered.

8.5.2.3 Where openings do not comply with the guidelines of Table 17, they shall be strengthened by providing reinforced concrete or reinforcing the brickwork (Fig. 25) with high strength deformed bars of 8 mm diameter but the quantity of steel shall be increased at the jambs to comply with **8.5.3.9**, if so required.

8.5.2.4 If a window or ventilator is to be projected out, the projection shall be in reinforced masonry or concrete and well anchored.

8.5.2.5 If an opening is tall (from bottom to almost top of a storey, thus dividing the wall into two portions), the adjoining portions shall be reinforced with horizontal reinforcement of 6 mm diameter bars at not more than 450 mm intervals, one on inner and one on outer face, properly tied to vertical steel at jambs, corners or junction of walls, where used.

8.5.2.6 The use of arches to span over the openings is a source of weakness and shall be avoided. When compelled to use, steel ties shall be provided.

8.5.3 *Earthquake Strengthening Arrangements*

8.5.3.1 All masonry buildings shall be strengthened by the methods specified for different types of buildings, as listed in Table 18, and detailed in subsequent clauses. Fig. 26 and Fig. 27 show, schematically, the overall strengthening arrangements to be adopted for types D and E buildings, which consist of horizontal bands of reinforcement at critical levels, vertical reinforcing bars at corners, junctions of walls and jambs of openings.

In four-storey buildings of type B, the requirements of vertical steel may be checked through an earthquake analysis using a design horizontal acceleration coefficient equal to 4 times that given in **5** of Part C/Section 1 of this NBCS. If this analysis shows that vertical steel is not required, the designer may take the decision accordingly.

Table 17 Size and Position of Openings in Bearing Walls

FIG. 27 OVERALL ARRANGEMENT OF REINFORCING MASONRY BUILDING HAVING PITCHED ROOF

8.5.3.2 Lintel band shall be provided at the lintel level on all load bearing internal, external longitudinal and cross walls, as per **8.5.3.5**. This band provided in panel or partition walls improves their stability during strong earthquake shaking.

8.5.3.3 Roof band shall be provided immediately below the roof or floors. The specifications of the band are given in **8.5.3.5**. Such a band need not be provided underneath reinforced concrete or brick-work slabs resting on bearing walls, provided that the slabs are continuous over the intermediate wall up to the crumple sections, if any, and cover the width of end walls, fully or at least three-fourths of the wall thickness.

8.5.3.4 Gable band is provided at the top of gable masonry below the purlins. The specifications of the band are given in **8.5.3.5**. This band shall be made continuous with the roof band at the eaves level.

8.5.3.5 *Section and reinforcement of band*

8.5.3.5.1 The band shall be as per **8.4.2**.

8.5.3.5.2 The bands shall be of the full width of the wall not less than 75 mm in depth and reinforced with longitudinal steel (Table 19). The longitudinal steel bars shall be held in position by steel links or stirrups 6 mm diameter spaced 150 mm apart. With respect to Table 19:

a) span of wall shall be the distance between centrelines of its cross walls or buttresses. For spans greater than 8 m intermediate pilasters or buttresses shall be provided or the adequacy of such long-span walls shall be ascertained through detailed analysis and full-scale test.

b) the numbers and diameter of bars given above pertain to high strength deformed bars.

c) the geometry of the bands shall be as per **8.4.2.2**.

d) concrete used in the bands shall be as per **8.3.4**.

e) the longitudinal steel bars shall be held in position by steel links or stirrups 6 mm diameter spaced at maximum 150 mm apart.

8.5.3.5.3 In reinforced brickwork, the thickness of joints containing steel bars shall be increased to have at least a minimum mortar cover of 10 mm around the bar. In bands of reinforced brickwork, the area of steel provided should be at least equal to that specified in Table 19.

8.5.3.5.4 For full integrity of walls at corners and junctions of walls and effective horizontal bending resistance of bands continuity of reinforcement is essential. The details as shown in Fig. 28 are recommended.

FIG. 28 REINFORCEMENT AND BENDING DETAIL IN RC BAND

8.5.3.6 Plinths band is provided at plinth level of walls on top of the foundation wall. This is to be provided where strip footings of masonry (other than reinforced concrete or reinforced masonry) are used and the soil is either soft or uneven in its properties. Where used, its section may be kept the same as in **8.5.3.5**. This band shall serve as damp proof course as well.

8.5.3.7 In Type D and E buildings, to further enhance the box action of walls, steel dowel bars may be used at corners and T-junctions of walls at the sill level of windows to length of 900 mm from the inside corner in each wall. Such dowel may be in the form of U stirrups 8 mm diameter. Where used, such bars must be laid in 1 : 3 cement sand mortar with a minimum clear cover of 10 mm on all sides to minimize corrosion.

8.5.3.8 *Vertical reinforcement*

Vertical steel at corners and junctions of walls, which are up to 340 mm (1½ brick) thick, shall be provided as specified in Table 20. For walls thicker than 340 mm, the area of the bars shall be proportionately increased. With respect to Table 20:

a) the diameters given above are for reinforcing steels of grade Fe415 or higher; and

b) typical details of providing vertical steel in brickwork masonry with rectangular solid units at corners and T-junctions are shown in Fig. 29. The vertical bars shall be covered with concrete of grade M20 or 1 : 3 mortar in suitably created pockets around the bars (Fig. 29). This shall ensure their safety from corrosion and good bond with masonry.

8.5.3.8.1 The vertical reinforcement shall be properly embedded in the plinth masonry of foundations and roof slab or roof band to develop its tensile strength in bond. It shall pass through the lintel bands and floor slabs or floor level bands in all storeys.

8.5.3.8.2 Bars in different storeys shall be lapped as per the requirements of Part C/Section 5 of this NBCS.

8.5.3.9 Vertical reinforcement of jambs of window and door openings shall be provided as per Table 20. It may start from the foundation of floor and terminate in lintel band (Fig. 29).

8.6 Floors/Roofs with Small Precast Components

8.6.1 *Types of Precast Floors/Roofs*

Earthquake resistance measures for floors and roofs with small precast components, as covered in this Section, have been dealt with as typical examples.

8.6.1.1 *Precast reinforced concrete unit roof/floor*

The unit is a precast reinforced concrete component, channel (inverted trough) shaped in section (*see* Fig. 30). The nominal width of the unit varies from 300 mm to 600 mm, its height from 150 mm to 200 mm and a minimum flange thickness of 30 mm. Length of unit shall vary according to room dimensions, but the maximum length is restricted to 4.2 m from stiffness considerations. Horizontal corrugations are provided on the two longitudinal faces of the units so that the structural roof/floor acts monolithic after concrete grouted in the joints between the units attains strength (*see* Fig. 31).

8.6.1.2 *Precast reinforced concrete cored unit roof/floor*

The unit is a reinforced concrete component having a nominal width of 300 to 600 mm and thickness of 130 to 150 mm having two circular hollows 90 mm diameter, throughout the length of the unit (*see* Fig. 32). The minimum flange/web thickness of the unit shall be 20 mm. Length of unit varies according to room dimensions, but the maximum length shall be restricted to 4.2 m from stiffness considerations. Horizontal corrugations are provided on the two longitudinal faces of the units so that the structural roof/floor acts monolithic after concrete grouted in the joints between the units attains strength (*see* Fig. 33).

8.6.1.3 *Precast reinforced concrete plank and joist scheme for roof/floor*

The scheme consists of precast reinforced concrete planks supported on partially precast reinforced concrete joists. The reinforced concrete planks are 300 mm wide and the length varies according to the spacing of the joists, but it shall not exceed 1.5 m (*see* Fig. 34). To provide monolithic property to the roof/floor and to have T-beam effect with the joists, the planks shall be made partially 30 mm thick and the partially 60 mm thick and *in-situ* concrete shall be filled in the depressed portions to complete the roof/floor structurally (*see* Fig. 35).

8.6.1.4 *Prefabricated brick panel system for roof/floor*

It consists of prefabricated reinforced brick panels (*see* Fig. 36) supported on Precast reinforced concrete joists with nominal reinforced 35 mm thick structural deck concrete over the brick panels and joists (*see* Fig. 37). The width of the brick panels shall be 530 mm for panels made of bricks of conventional size and 450 mm for panels made of bricks of modular size. The thickness of the panels shall be 75 mm or 90 mm, respectively depending upon whether conventional or modular bricks are used. The length of the panels shall vary depending upon the spacing of the joists, but the maximum length shall not exceed 1.2 m.

8.6.1.5 *Precast reinforced concrete waffle unit roof/floor*

Waffle units are of the shape of inverted troughs, square or rectangular in plan, having lateral dimensions up to 1.2 m and depth depending upon the span of the roof/floor to be covered (*see* Fig. 38 and Fig. 39). The minimum thickness of flange/web shall be 35 mm. Horizontal projections may be provided on all the four external faces of the unit and the unit shall be so shaped that it shall act monolithic with *in-situ* concrete to ensure load transfer. Vertical castellation, called shear keys, shall be provided on all the four external faces of the precast units to enable them to transfer horizontal shear force from one unit to adjacent unit through *in-situ* concrete filled in the joints between the units. The waffle units shall be laid in a grid pattern with gaps between two adjacent units, and reinforcement, as per design, and structural concrete shall be provided in the gaps between the units in both the directions. The scheme is suitable for two way spanning roofs and floors of buildings having large spans.

8.6.2 *Seismic Resistance Measures*

8.6.2.1 All floors and roofs to be constructed with small precast components shall be strengthened as specified for various categories of buildings in Table 21. The strengthening measures are detailed in **8.6.2.3** and **8.6.2.8**.

8.6.2.2 Vertical castellation, called shear keys, shall be provided on the longitudinal faces of the channel, cored and waffle units to enable them to transfer horizontal shear force from one unit to the adjacent unit through the *in-situ* concrete filled in the joints between the units. The minimum percentage of area of shear keys as calculated below, on each face of the unit, shall be 15.

Shear keys shall have a minimum width of 40 mm at its root with the body of the component and shall be to the full height of the component and preferably at uniform spacing. Percentage of area of shear keys shall be calculated as:

$$\frac{\text{No. of shear keys on one face of the component } \times 40}{\text{Length of the face of the component, in mm}} \times 100$$

Table 21 Strengthening Measures for Floors/Roofs with Small Precast Components

NOTES

1 Tie beam as per **8.6.2.3**;

2 Reinforcing bars of precast unit and tied to tie beam reinforcement as per **8.6.2.4**;

3 Reinforced deck concrete as per **8.6.2.5**;

4 Reinforced deck concrete as per **8.6.2.6**; and

5 Reinforced bars in joint between precast waffle units tied to tie beam reinforcement as per **8.6.2.7**.

8.6.2.3 Tie beam (*see* Table 20) is a beam provided all round the floor or roof to bind together all the precast components to make it a diaphragm. The beams shall be to the full width of the supporting wall or beam less the bearing of the precast components. The depth of the beam shall be equal to the depth of the precast components plus the thickness of structural deck concrete, where used over the components. The beam shall be made of cement concrete of grade not leaner than M15 and shall be reinforced as indicated in Table 18. If depth of tie is more than 75 mm, equivalent reinforcement shall be provided with one bar of minimum diameter 8 mm at each corner. Tie beams shall be provided on all longitudinal and cross walls. Typical details of the beams are shown in Fig. 40 to Fig. 44.

NOTE — Adequate edge support say 60 mm, shall be provided to precast element on the wall so as to avert its slippage during seismic ground motion.

8.6.2.4 Top reinforcement in the channel or cored units (*see* Table 21) shall be projected out at both the ends for anchorage length and tied to tie beam reinforcement.

8.6.2.5 Structural deck concrete (*see* Table 21) of grade not leaner than M15 shall be provided over precast components or act monolithic. Wherever, deck concrete is to be provided, the top surface of the components shall be finished rough. Cement slurry with 0.5 kg of cement/m^2 of the surface area shall be applied over the components immediately before laying the deck concrete and the concrete shall be compacted using plate vibrators. The minimum thickness of deck concrete shall be 35 mm or 40 mm reinforced with 6 mm diameter bars and 150 mm apart both ways and anchored into the tie beam placed all round. The maximum size of coarse aggregate used in deck concrete shall not exceed 12 mm.

NOTE — Under conditions of economic constraints, the deck concrete itself could serve as floor finish. The concrete is laid in one operation (*see* Fig. 44) without joints.

8.6.2.6 The deck concrete normally used over the brick panel with joist floor shall be reinforced with 6 mm diameter bars spaced 150 mm apart both ways (*see* Table 21).

8.6.2.7 For floors/roofs with precast waffle units, two 16 mm diameter high strength deformed bars shall be provided as top reinforcement in the joints between waffle units, in addition to reinforcement required for taking bending moment for vertical loads. This reinforcement (*see* Table 21) shall be fixed to tie beam reinforcement.

8.6.2.8 In case of floors/roofs with precast components other than those indicated in Table 21, the buildings shall be analysed for maximum expected seismic forces and the floor/roof shall be designed to act as diaphragm and take care of the resulting forces.

8.7 Timber Construction

8.7.1 Timber has higher strength per unit weight and is, therefore, very suitable for earthquake resistant construction. Materials, design and construction in timber shall generally conform to good practice [C-4(9)].

8.7.2 Timber (with masonry in-fill) construction shall generally be restricted to two storeys with or without the attic floor.

8.7.3 In timber (with masonry in-fill) construction attention shall be paid to fire safety against electric short circuiting, kitchen fire, etc.

8.7.4 The superstructure of timber buildings shall be made rigid against deformations by adopting suitable construction details at the junctions of the framing members and in wall panels as given in **8.7.6** to **8.7.10** so that the construction as a whole behaves as one unit against earthquake forces.

8.7.5 *Foundations*

8.7.5.1 Timber construction shall preferably start above the plinth level, the portion below shall be in masonry or concrete.

8.7.5.2 The superstructure may be connected with the foundation in one of the two ways as given below:

a) The superstructure may simply rest on the plinth masonry, or in the case of small buildings of one storey having plan area less than about 50 m^2, it may rest on firm plane ground so that the building is free to slide laterally during ground motion; and

NOTES

1 Past experience has shown that superstructure of the buildings not fixed with the foundation escaped collapse even in a severe earthquake although they were shifted sideways.

2 Where fittings for water supply or water borne sanitation from the house are to be installed, proper attention should be given to permit movement so as to avoid fracture of damage to pipes.

b) The superstructure may be rigidly fixed into the plinth masonry or concrete foundation as given in Fig. 45 or in case of small building having plan area less than 50 m^2, it may be fixed to vertical poles embedded into the ground. In each case the building is likely to move along with its foundation. Therefore, the superstructure shall be designed to carry the resulting earthquake shears.

REINFORCEMENT OF THE BEAM
WALL BEAM
WALL BEAM

FIG. 40 CONNECTION OF PRECAST CORED/CHANNEL UNIT WITH TIE BEAM

8.7.6 *Types of Framing*

The types of construction usually adopted in timber building are as follows:

a) Stud wall construction; and

b) Brick nogged timber frame construction.

8.7.7 *Stud Wall Construction*

8.7.7.1 The stud wall construction consists of timber studs and corner posts framed into sills, top plates and wall plates. Horizontal struts and diagonal braces are used to stiffen the frame against lateral loads. The wall covering may consist of *EKRA*, timber or like. Typical details of stud walls are shown in Fig. 46. Minimum sizes and spacing of various members used are specified in **8.7.7.2** to **8.7.7.10**.

8.7.7.2 The timber studs for use in load bearing walls shall have a minimum finished size of 40 mm × 90 mm and their spacing shall not exceed those given in Table 22.

8.7.7.3 The timber studs in non-load bearing walls shall not be less than 40 mm × 70 mm in finished cross section. Their spacing shall not exceed 1 m.

8.7.7.4 There shall be at least one diagonal brace for every 1.6 m × 1 m area of load bearing walls. Their minimum finished sizes shall be in accordance with Table 23.

8.7.7.5 The horizontal struts shall be spaced not more than 1 m apart. They shall have a minimum size of 30 mm × 40 mm for all locations.

8.7.7.6 The finished sizes of the sill, the wall plate and top plate shall not be less than the size of the studs used in the wall.

8.7.7.7 The corner posts shall consist of three timbers, two being equal in size to the studs used in the walls meeting at the corner and the third timber being of a size to fit so as to make a rectangular section (*see* Fig. 46).

46 B TIMBER FRAMING IN STUD WALL CONSTRUCTION WITH OPENING IN WALL

All dimensions in millimetres.

FIG. 46 STUD WALL CONSTRUCTION

8.7.7.8 The diagonal braces shall be connected at their ends with the stud wall members by means of wire nails having 6 gauge (4.88 mm diameter) and 100 mm length. Their minimum number shall be 4 nails for 20 mm × 40 mm braces and 6 nails for 30 mm × 40 mm braces. The far end of nails may be clutched as far as possible.

8.7.7.9 Horizontal bracing shall be provided at corners of T-junctions of walls at sill, first floor and eaves levels. The bracing members shall have a minimum finished size of 20 mm × 90 mm and shall be connected by means of wire nails to the wall plates at a distance between 1.2 m and 1.8 m measured from the junction of the walls. There shall be a minimum number of six nails of 6 gauge (4.88 mm diameter) and 10 cm length with clutching as far ends.

8.7.7.10 Unsheathed studding shall not be used adjacent to the wall of another building. The studding shall be sheathed with close jointed 20 mm or thicker boards.

8.7.8 *Brick Nogged Timber Frame Construction*

8.7.8.1 The brick nogged timber frame consists of intermediate verticals, columns, sills, wall plates, horizontal nogging members and diagonal braces framed into each other and the space between framing members filled with tight-fitting brick masonry in stretcher bond. Typical details of brick nogged timber frame construction are shown in Fig. 47. Minimum sizes and spacing of various elements used are specified in **8.7.8.2** to **8.7.8.9**.

8.7.8.2 The vertical framing members in brick nogged load bearing walls shall have minimum finished sizes as specified in Table 23.

8.7.8.3 The minimum finished size of the vertical members in non-load bearing walls shall be 40 mm × 100 mm spaced not more than 1.5 m apart.

8.7.8.4 The sizes of diagonal bracing members shall be the same as in Table 23.

8.7.8.5 The horizontal framing members in brick-nogged construction shall be spaced not more than 1 m apart. Their minimum finished sizes shall be in accordance with Table 24 and Table 25.

8.7.8.6 The finished sizes of the sill, wall plate and top plate shall be not less than the size of the vertical members used in the wall.

8.7.8.7 Corner posts shall consist of three vertical timbers as described in **8.7.7.7**.

8.7.8.8 The diagonal braces shall be connected of their ends with the other members of the wall by means of wire nails as specified in **8.7.7.8**.

8.7.8.9 Horizontal bracing members of corners of T-junctions of wall shall be as specified in **8.7.7.9**.

8.7.9 *Notching and Cutting*

8.7.9.1 Timber framing frequently requires notching and cutting of the vertical members. The notching or cutting should in general be limited to 20 mm in depth unless steel strips are provided to strengthen the notched face of the members. Such steel strips, where necessary shall be at least 1.5 mm thick and 35 mm wide extending at least 150 mm beyond each side of the notch or cut and attached to the vertical member by means of bolts or screws at each end.

8.7.9.2 The top plate, the wall plate or the sill of a wall may be notched or cut, if reinforcing strip of iron is provided as specified in **8.7.9.1**. In case the member is notched or cut not to exceed 40 mm in depth, such reinforcing strip may be placed along the notched edge only. Where the notch or cut is more than 40 mm in depth or the member is completely cut through, such reinforcing strips shall be placed on both edges of the member. The details of notching and cutting are shown in Fig. 48.

8.7.9.3 Joints in timber shall preferably be bound by metallic fasteners.

8.7.10 *Bridging and Blocking*

8.7.10.1 All wooden joists shall have at least one row of cross bridging for every 3.5 m length of span. The cross-section of the bridging member shall be a minimum of 40 mm × 70 mm and the member shall be screwed or nailed to the joists.

8.7.10.2 All spaces between joists shall be blocked at all bearing with solid blocks not less than 40 mm thick and the full depth of the joists. The block shall be screwed or nailed to the joists as well as to the bearings.

9 CONFINED MASONRY WALLS (CMW)

9.1 Design Considerations

9.1.1 *General*

The provisions given in 9.1.2 to 9.1.6 apply in addition to those specified in 4.

9.1.2 *Structural Integrity*

Intersecting walls shall be joined together to resist the effect of gravity and lateral loads. The walls shall be adequately connected to elements which provide lateral support, such as floors and roofs.

9.1.3 *Building Configuration*

A regular building configuration is one of the key requirements for satisfactory earthquake performance. The following recommendations related to building plan shape shall be followed:

a) The building's length-to-width ratio in plan shall not exceed 4 and storey height shall be less than 4 m;

b) The walls shall be built in a symmetrical manner with regard to the horizontal axes through the centre of the building plan. Some walls shall be placed on the perimeter also to increase resistance of the building to twisting (torsion) during an earthquake;

c) There shall be at least two lines of walls in each orthogonal direction of the building plan, and the walls along each line shall extend over at least 50 percent of the building dimension in the direction considered at each storey level (Fig. 49);

d) The walls shall be continuous up to the full building height. There shall be no vertical offsets in the walls along the building height;

e) The openings (doors and windows) shall be placed in the same position on each floor;

f) The total cross-sectional area of all walls in two adjacent floors shall not be different by more than 30 percent; and

g) The structural system in a building shall be the same in all storeys and in both principal plan directions.

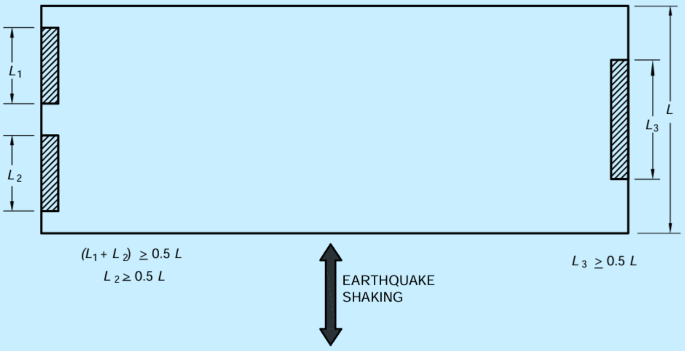

FIG. 49 AT LEAST TWO PARALLEL LINES OF WALLS ARE REQUIRED IN EACH PLAN DIRECTION

9.1.4 *Minimum Design Dimensions and Placements of Confining Elements*

Requirements regarding spacing of tie-columns and tie-beams are presented in Fig. 50. Minimum dimension of tie-column and tie-beam shall be 150 mm along the wall direction and as much as the thickness of the wall in the direction perpendicular to it.

9.1.4.1 *Placement of reinforced concrete tie-columns and tie-beams*

Tie-columns should be provided at:

a) intersections of walls;

b) intermediate locations in longer walls, where spacing shall not exceed lesser than 1.5 h (where h is the clear wall height between floors) or 4 m; and

c) free ends of wall panels that provide lateral load resistance to the building (Fig. 51).

Also, reinforced concrete tie-beams must be provided at the top of each wall and spacing between tie-beams should be preferably less than 4 m.

9.1.4.2 *Horizontal lintel bands*

When the unsupported height of the wall h is greater than 2.5 m, a continuous horizontal lintel band shall be provided over the openings. A continuous horizontal band is not essential for $h < 2.5$ m, but a lintel beam shall be provided above the openings.

9.1.5 *Minimum Dimensions of Masonry Walls*

The following shall be applicable:

a) the wall thickness (t) shall not be less than 110 mm; and

b) the maximum wall height-to-thickness (h/t) ratio shall not exceed 25, where h is the height between floors.

TIE-COLUMN AT WALL INTERACTIONS

FIG. 50 REQUIREMENTS REGARDING CONFINING ELEMENTS

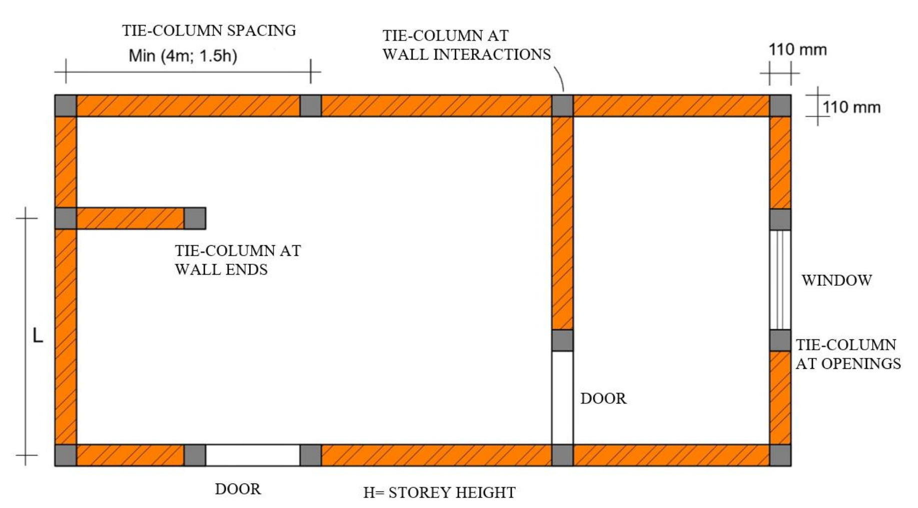

FIG. 51 TYPICAL PLAN ILLUSTRATING THE PLACEMENT OF RC TIE COLUMNS

9.1.5.1 *Aspect Ratio of Confined Masonry Walls*

The height-to-width ratio of a wall that is a part of the lateral force-resisting system shall be less than or equal to 2.

9.1.5.2 *Parapets*

RC tie-columns and tie-beams shall extend to the top of the parapet Fig. 51. When a parapet is not confined by tie-beams, its height shall not be more than 3 times its thickness. For parapet walls with top tie-beams, the height shall not be more than 1.2 m.

9.1.5.3 *Gable Walls*

The top of gable shall be confined with reinforced concrete tie-beams, and tie-columns located at the middle of the gable wall shall be extended from the lower floor to the top of gable wall (whenever applicable), as shown in Fig. 52(A) Alternatively, a gable portion of the wall can be made of timber or other light-weight material that is continuous Fig. 52(B).

9.1.6 *Walls with Openings*

9.1.6.1 *Size of opening*

The presence of large openings may have a negative effect on earthquake performance of confined masonry buildings, especially if openings are not confined. A large opening has a total area greater than 10 percent of the wall panel area, while a small opening has a total area less than or equal to 10 percent of the wall panel area.

9.1.6.2 *Walls with large openings*

The following three approaches shall be followed in walls with large openings:

a) when reinforced concrete tie-columns are not provided at the ends of an opening, the panel shall not be considered as confined and its contribution to earthquake resistance of the building shall be disregarded but shall be strengthened [*see* Fig. 53(A)];

b) when reinforced concrete tie-columns are provided at the opening, and the confined masonry panels are considered to contribute to earthquake resistance of the building, the aspect ratio *H*/*L* of these panels shall be less than 2.0 [Fig. 53(B)]. Better performance can be achieved by providing both sill and lintel bands below and above the openings, respectively; and

c) if total area of openings is greater than 25 percent, both openings and masonry piers shall be confined with horizontal and vertical confining elements [Fig. 53(C)].

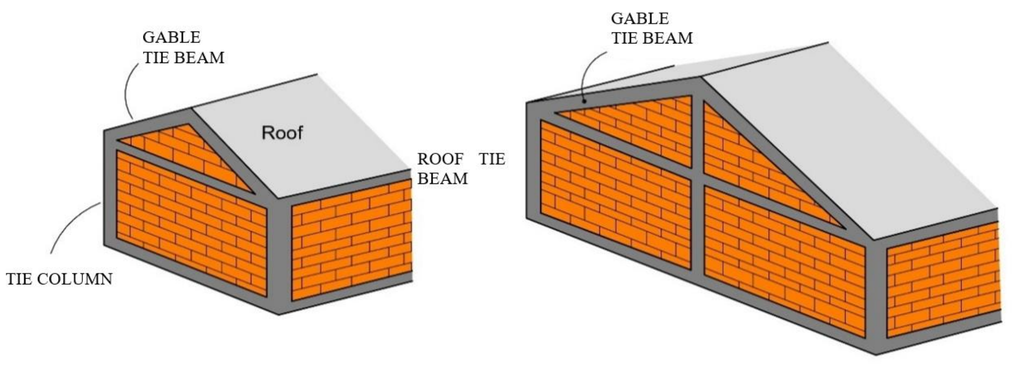

FIG. 52(A) CONFINING ELEMENTS

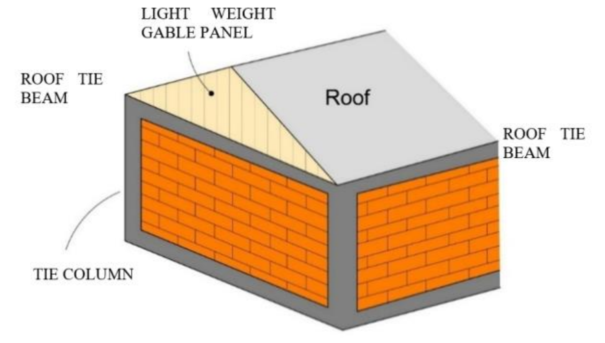

FIG. 52(B) LIGHT-WEIGHT GABLE PANELS

FIG. 52 TYPES OF GABLE WALLS

9.1.6.3 *Walls with small and single openings*

The following three approaches shall be followed in walls with small openings:

a) when the opening is located outside the diagonals Fig. 54(a), it shall be ignored, and the entire wall cross-sectional area considered for earthquake resistance;

b) when an opening is located at the intersection of the panel diagonals [Fig. 54(b)], the panel cross-sectional area (A_T) considered for earthquake resistance should exclude the opening length; and

c) when an opening is located close to one end of the panel, the panel cross-sectional area (A_T) considered in earthquake resistance shall use the larger pier length [Fig. 54(c)].

9.2 Structural Design

9.2.1 *Design Criteria*

Design of structural elements shall be performed as per the working stress method.

9.2.2 *Structural Design as per Working Stress Method*

9.2.2.1 *Load combinations*

The working stress method shall be employed for the structural design of SEs of confined masonry buildings for the load combinations specified in **5** of Part C/Section 1 of this NBCS.

9.2.2.2 *Transformed section properties*

Confined masonry wall panel shall be treated as a composite structural element which consists of a masonry wall and reinforced concrete tie-columns, and designed as a transformed section. Modular ratio (m) shall be taken as the ratio of elastic modulus for concrete and masonry. The modulus of elasticity of concrete can be taken as per

Part C/Section 5 of this NBCS and modulus of elasticity of masonry as per **5.4.6**. Transformed section properties of a confined masonry panel used in design are illustrated in Fig. 55.

9.2.2.3 *Permissible compressive force*

Compressive force in confined masonry due to axial load shall not exceed that given by:

$$P_o = (0.25\,f_m\,A_m + f_{cc}\,A_c + 0.65\,A_s\,f_s)\,k_s,$$

where

A_c = cross-sectional area of concrete excluding reinforcing steel;

A_m = net area of masonry;

A_s = area of steel;

f_{cc} = permissible stress in concrete in direct compression as per Part C/Section 5 of this NBCS;

f_m = compressive strength of masonry as per **5.4.5**;

f_s = permissible steel tensile stress as per Part C/Section 5 of this NBCS; and

k_s = stress reduction factor as per Table 10.

ii)	> 1	$0.083\sqrt{f_m}$	0.4

9.2.2.4 *Combined permissible axial and flexural compressive stress*

For walls subjected to combined axial load and flexure, the compressive stress in masonry due to combined action of axial load and bending shall not exceed 1.25 f_a and compressive stress in masonry due to axial load only shall not exceed f_a.

9.2.2.5 *Permissible tensile stress*

Provisions of **5.4.2** shall apply.

9.2.2.6 *Permissible shear stress*

The permissible shear stress τ_{cm} for confined masonry walls shall be as per Table 26. If there is tension in any part of a section of masonry, the area under tension shall be ignored while estimating the shear stress demand on the cross-section.

When designing buildings as per the working stress method, the load combinations given in Table 27 shall be used. These combinations are provided considering short-term effects. When assessing the long-term effects due to creep, the dead load, and that part of imposed load likely to be permanent alone shall be used.

Table 27 Load Combinations to be Considered in Design of Buildings as per Working Stress Method

Sl No. (1)	Combination Case (2)	Serviceability Load Combination (3)
i)	1	DL + IL
ii)	2	DL + EL
iii)	3	DL + 0.8 IL + 0.8 EL

9.2.2.7 *Design assumptions*

The following assumptions shall be made in design of confined masonry wall panels subjected to axial and/or flexural loads:

a) masonry behaves like a homogeneous material;

b) strain distribution across the cross-section of the wall varies linearly;

c) tensile stresses are resisted only by reinforcing steel (masonry and concrete tensile resistance is ignored);

d) bond is perfect between steel reinforcement and adjacent concrete;

e) maximum compressive strains in masonry (ε_m) and concrete (ε_c) shall be taken equal to 0.004 0 and 0.003 0, respectively; and the stress-strain curve of masonry is linear, unless a more accurate relation is determined by experimental study of masonry prisms.

9.2.2.8 *Stress-strain curves for concrete, masonry and steel*

The relationship between the compressive stress distribution in concrete and the strain in concrete may be assumed to be rectangle, trapezoid, parabola, or any other shape which results in prediction of strength in substantial agreement with the results of test. An acceptable stress-strain curve is given in Part C/Section 5 of this NBCS. But the ultimate strain in concrete shall be taken as 0.003 0 in place of 0.003 5. For design purposes, the compressive strength of concrete in the structure shall be assumed to be 0.67 times the characteristic strength. The partial safety factor γ_m of 1.5 shall be applied in addition to this.

The stresses in the reinforcement are derived from representative stress-strain curve for the type of steel used. Typical curves are given in Part C/Section 5 of this NBCS. For design purposes, the partial safety factor γ_m of 1.15 shall be applied.

The relation between the compressive stress-strain in masonry may be assumed to be rectangle, trapezoid, parabola, or any other shape which results in prediction of strength in substantial agreement with the results of test. An acceptable stress-strain curve is given in Fig. 56. For design purposes the partial safety factor γ_m of 2.0 shall be applied.

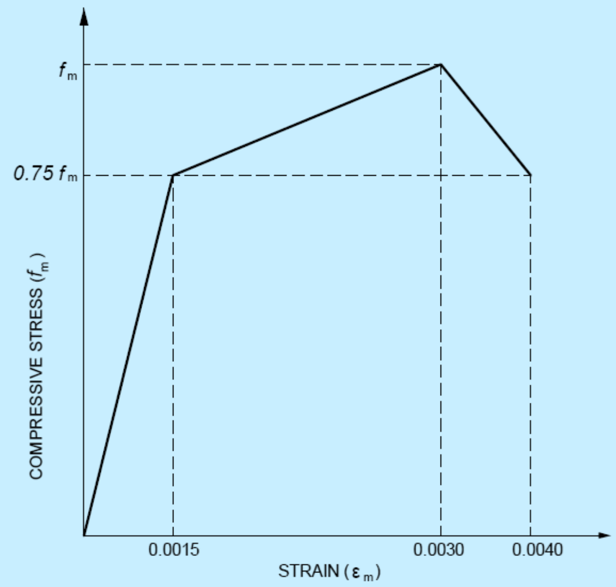

FIG. 56 ACCEPTABLE STRESS-STRAIN CURVE OF MASONRY

9.2.2.9 *Axial load resistance*

Axial load resistance of a confined masonry wall (*P*u) shall be determined considering the contribution of masonry and longitudinal steel reinforcement in tie-columns assuming that the steel has yielded in compression, that is:

$$P_u = (0.4\,f_m\,A_m + 0.45\,f_{ck}\,A_c + 0.75\,f_y\,A_s)\,k_s,$$

where

f_m = compressive strength of masonry;

A_m = net area of masonry;

f_{ck} = characteristic cube compressive strength of concrete;

A_c = cross-sectional area of concrete excluding reinforcing steel;

f_y = characteristic yield strength of the reinforcing steel;

A_s = area of steel; and

k_s = stress reduction factor as in Table 10.

9.2.2.10 *Design of confined masonry walls for combined axial load and out-of-plane bending*

Confined masonry walls need to be designed for combined effects of axial load and out-of-plane bending (bending perpendicular to the wall surface). Bending moments may be due to eccentric gravity loads or lateral loads acting perpendicular to wall plane (wind and earthquake). Generally, confined masonry walls have sufficient resistance against earthquake force acting in out-of-plane direction if slenderness limits in **9.4.1** are satisfied. For out-of-plane forces, only one-way bending may be considered, that is, bending in the vertical direction as shown in Fig. 57.

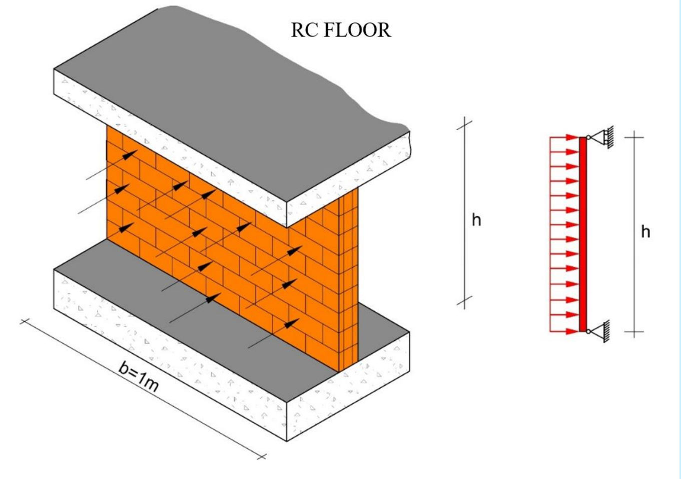

FIG. 57 UNIT LENGTH B OF MASONRY WALL CONSIDERED FOR OUT-OF-PLANE BENDING IN VERTICAL DIRECTION

The interaction of compression due to axial stresses and bending stresses should be within the following limits:

$$\frac{P}{P_u} + \frac{M}{M_u} \leq 1.0$$

Design bending moment demand M due to design wind pressure p_d [as per Part C/Section 1 of this NBCS] acting out-of-plane over unit length b can be calculated as follows:

$$M = \frac{p_d h^2}{8}$$

where h is floor-to-floor height. The axial resistance P_u shall be calculated as per **9.2.2.9** by ignoring the contribution of concrete and reinforcement in tie-column and considering the net area of masonry per unit length $A_m^{'}$. The moment of resistance M_u per unit length shall be estimated for bending about horizontal axis normal to the length of wall as follows:

$$M_u = \left(\frac{f_t}{\gamma_m} + \frac{P}{A_m^{'}} \right) S_m^{'}$$

where axial load P should not exceed self-weight of the unit length of panel plus $0.15A_m^{'}$ (in MPa),

where

f_t = flexural tensile strength normal to bed joints;

$$= \begin{cases} 0.3 \text{ MPa} & \text{Grade M1 or better Mortar} \\ 0.2 \text{ MPa} & \text{Grade M2 Mortar} \end{cases}$$

A'_{m} = net area of masonry per unit length (mm^2); and

S'_{m} = section modulus per unit length (mm^3).

9.2.2.11 *Moment resistance of confined masonry walls due to combined axial load and in-plane bending*

a) *General approach* — Moment resistance M_u for a section of a confined masonry wall subjected to the design axial load P shall be determined from equilibrium of internal forces acting on the section, by following the assumptions stated in **9.2.2.7**; and

b) *Simplified axial load and bending moment interaction diagram* — For walls with longitudinal bars placed symmetrically in tie-columns, the following equations define a simplified axial load-bending moment interaction diagram (Fig. 58):

$$M_{\mathrm{u}} = \begin{cases} 0.3Pd + M_{\mathrm{uf}} & \text{Points A-B :: } 0 \leq P < (P_{\mathrm{u}}/3) \\ 0.10Pd + M_{\mathrm{uf}} & \text{Point B :: } P = (P_{\mathrm{u}}/3) \\ \dfrac{2}{3}(0.05Pd + 1.5M_{\mathrm{uf}}) & \text{Point C :: } P = (P_{\mathrm{u}}/3) \\ \left(1 - \dfrac{P}{P_{\mathrm{u}}}\right)(0.15Pd + 1.5M_{\mathrm{uf}}) & \text{Points A-B :: } P > (P_{\mathrm{u}}/3) \end{cases}$$

where

M_{f} = $0.87 f_{\mathrm{y}} A_{\mathrm{s}} (l_{\mathrm{w}} - b)$ is the moment resistance corresponding to pure bending load condition, and d the effective depth of the wall section.

c) *Alternate method* — The P-M interaction curve for the confined masonry section can also be determined by sectional analysis method employed in reinforced concrete members.

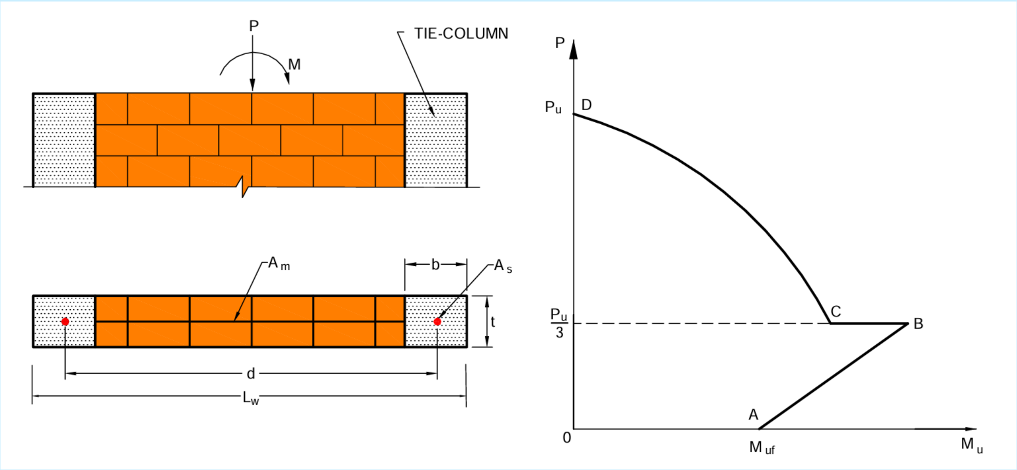

FIG. 58 SIMPLIFIED INTERACTION DIAGRAM FOR DESIGN OF CONFINED MASONRY WALLS

9.2.2.12 *Design for shear*

Shear resistance of a confined masonry wall is due to combined contribution of masonry and horizontal wall reinforcement. Although reinforced concrete tie-columns contribute to shear resistance of a confined masonry wall, their contribution shall be ignored in the design of confined masonry structure.

a) *Masonry shear resistance*

1) *Empirical expression method* — Shear strength of masonry wall may be estimated by any of the following methods:

Shear resistance V_u provided by masonry wall shall be determined as:

$$V_u = 0.8(0.5 v_m A_T + 0.4 P_d) f \leq 1.5 v_m A_T$$

where

A_T = area of cross-section of confined masonry wall including tie-columns;

f = corrected factor for the aspect ratio H/L of the wall;

$$= \begin{cases} 1.55 & \left(\frac{H}{L}\right) \leq 0.2 \\ 1.70 - 0.7\left(\frac{H}{L}\right) & 0.2 < \left(\frac{H}{L}\right) \leq 1.0 \\ 1.00 & 1.0 < \left(\frac{H}{L}\right) \end{cases} ;$$

P_d = design compressive axial load which shall include permanent loads only and with the partial safety factor of 1.0;

v_m = masonry shear strength; and

$= 0.16\sqrt{f_m} \leq 0.6$ MPa.

2) *Test method* — Shear resistance V_u of masonry wall shall be determined as:

$$V_u = v_m A_T$$

where, v_m can be obtained from the standard test method for diagonal tension (shear) in masonry assemblages as given hereunder:

i) When shear strength v_m of masonry is to be established by tests, it shall be done in advance of the construction, using masonry specimens built of similar materials under the same conditions with the same bonding arrangement as for the structure. In making the specimens, moisture content of the units at the time of laying, the consistency of the mortar, the thickness of mortar joints and workmanship shall be the same as will be used in the structure.

The walls specimens (Fig. 59) shall have a length at least two and a half times the length of the masonry unit in one direction and adequate number of courses in perpendicular direction so that the specimen has approximately square shape. The sides of the specimen may not be less than 600 mm. The walls specimens shall be tested by loading them in compression along one diagonal. Tests shall be conducted on at least three specimens constructed with the same size and type of masonry units, mortar, and workmanship.

Specimens shall be tested after 28 days and two steel loading shoes (Fig. 59) shall be used to apply the machine load to the specimen. For the distribution of the applied load P_s, the ratio of the length of bearing, l_b and the width or height of specimen must be equal to or greater than 0.2. The load shall be applied at the rate of 50 kN/min to 100 kN/min and the load at failure shall be recorded. Load shall be applied at a uniform rate so that the maximum load is reached in not less than 1 min and not more than 2 min. Minimum thickness of steel plate used for loading shoe shall be 12 mm.

ii) The shear stress strength v_m of the specimen as:

$$v_m = \frac{P_s}{A_{sn}\sqrt{2}}$$

where

A_{sn} = net area (mm^2) of the wall specimen;

$= \left(\frac{w_s + n_s}{2}\right) t_s$;

P_s = applied design axial load (N);

h_s = height (mm);

t_s = total thickness (mm) of the wall specimen; and

w_s = width (mm).

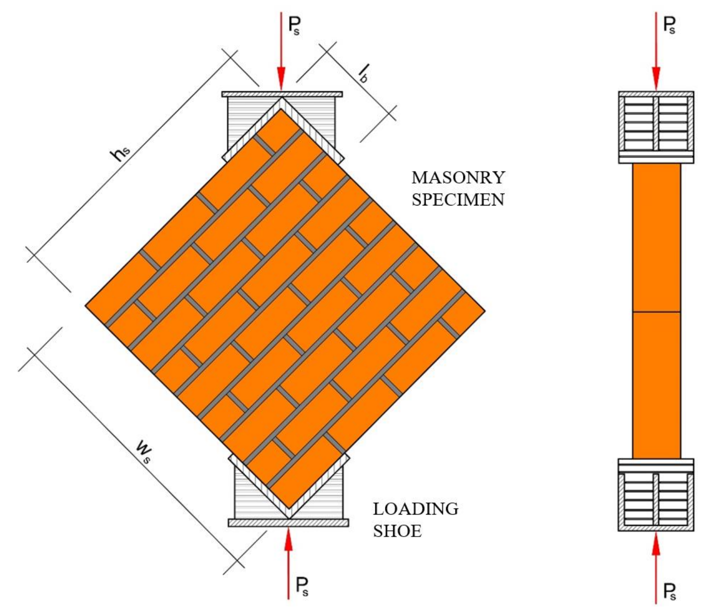

FIG. 59 WALL SPECIMEN FOR DIAGONAL COMPRESSION TEST

b) *Alternate method* (*Strut-and-Tie method*)

The Strut-and-Tie method can be used for determining the shear capacity of confined masonry walls. This method provides a rational and consistent design approach by idealizing complex structural members with an appropriate simplified truss model. According to this procedure, based on the knowledge of direction of principal stresses, load paths are drawn through the wall in form of a truss which is analyzed for the design loads. A possible strut-and-tie model for the confined masonry wall based on its load resisting mechanism is illustrated in Fig. 60; the broken and solid lines represent the strut and tie, respectively. If the opening distribution is irregular or complex in elevation, strut and tie method can be used to estimate the in-plane resistance of the confined masonry wall.

The basic prerequisites for the strut-and-tie model are as follows:

a) The equilibrium of forces at nodes should be maintained for a given set of loads;

b) Tension in concrete and masonry is neglected and adequate detailing of anchorage shall be provided for tie reinforcement;

c) The member forces in the struts and ties are uniaxial which shall not exceed the corresponding member strength at every section; and

d) Sufficient ductility shall be available to make the transition from elastic to plastic behaviour which will enable redistribution of internal forces in the members.

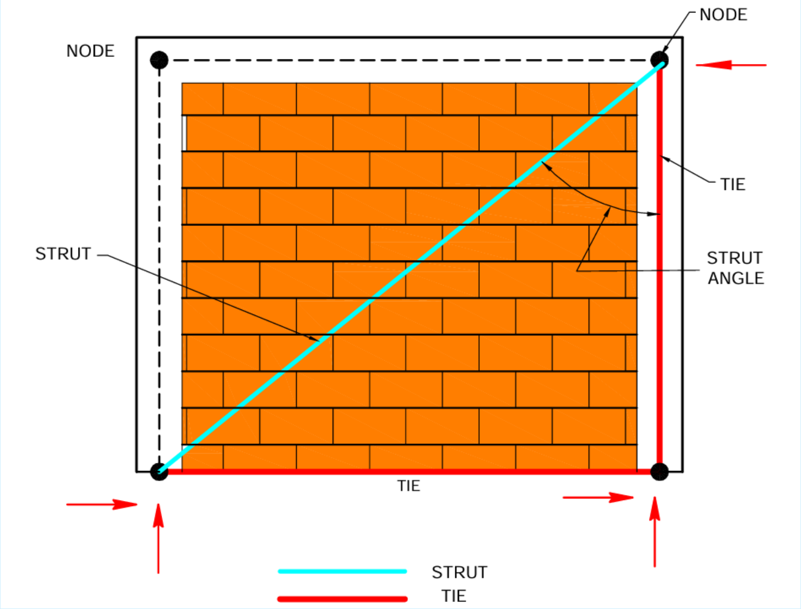

FIG. 60 STRUT-AND-TIE MODEL OF CONFINED MASONRY WALLS

9.2.2.13 *Design of tie-columns and tie-beams*

a) *Minimum amount of longitudinal reinforcement*

Longitudinal reinforcement in tie-columns and tie-beams shall be proportioned to resist the corresponding vertical and horizontal components of the compression strut that develops in masonry when resisting combined gravity and lateral loads. The total area of reinforcement shall be not less than 0.8 percent of the gross cross-section area of the column. For a 2-storey height, the minimum area of reinforcement can be 0.6 percent;

b) *Minimum amount of transverse reinforcement* (*Ties*)

Tie-columns and tie-beams shall have transverse reinforcement in the form of closed stirrups (ties) with the minimum total cross-sectional area A_{sc} (mm^2) of stirrup legs effective in shear equal to:

$$A_{sc} = 0.001\,2\, s h_c,$$

where

s = tie spacing, in mm; and

h_c = Dimension, in mm of tie-column or tie-beam in the wall plane.

c) *Spacing of transverse reinforcement*

Tie spacing shall not exceed the lesser of 200 mm and $1.5t$.

9.2.3 *Foundations and Plinth Construction*

The foundation shall be constructed in a similar manner as for traditional masonry construction. Either a brick masonry footing or an RC strip footing can be used. An RC plinth band shall be constructed on top of the foundation. A plinth band shall be provided to fully confine wall panels along their bases and prevent excessive wall damage due to building settlement in soft soil areas. Note that the longitudinal reinforcement shall be extended from an RC tie-column into the plinth band, and whenever possible, into the foundation.

9.3 Earthquake Resistant Design

9.3.1 *Basis*

Building shall be designed for earthquake forces determined as per **5** of Part C/Section 1 of this NBCS. Also, the load combinations shall be as per Part C/Section 1 of this NBCS.

9.3.2 *Methods of Earthquake Analysis*

9.3.2.1 *General considerations*

9.3.2.1.1 For determining internal forces and moments acting on confined masonry walls, the building may be analyzed for estimating the effects of earthquake shaking using either the simplified method or the earthquake analysis methods specified in **5** of Part C/Section 1 of this NBCS. The simplified method can be used for buildings up to three storeys high, provided that the requirements stipulated in **9.3.2.2** have been met.

The effect of openings shall be considered in lateral stiffness and strength calculations. The structure shall be modelled to adequately simulate the behaviour of its critical structural elements. Modulus of elasticity E_m and shear modulus G_m of masonry shall be used to reflect the axial and shear stiffness expected in the structure.

9.3.2.1.2 Design forces and moments shall be obtained from the analysis using design loads and the corresponding load combinations specified in **5** of Part C/Section 1 of this NBCS. A confined masonry wall shall be designed for the effects of gravity loads, and the effects of lateral loads, including shear force, in-plane bending, and out-of-plane bending moments. When the simplified method is used, design for lateral loads may be limited to the effects of shear force.

9.3.2.2 *Applicability of the simplified method*

9.3.2.2.1 The simplified method is based on an idealized distribution of lateral earthquake forces in regular load bearing wall buildings with rigid diaphragms. The method compares the shear capacity of all walls at the base of the building and the earthquake base shear force determined from **5** of Part C/Section 1 of this NBCS. It is suitable for verifying adequacy of regular buildings with symmetrical wall layout and predominant shear behaviour. The method does not consider torsional effects, arising from eccentricity between centre of mass and centre of resistance. Due to its assumptions, application of this method is restricted to buildings with a height not exceeding three storeys.

9.3.2.2.2 The design can be simplified further for small buildings by applying the concept of wall index, as per procedure in **9.3.2.3**, which can be used for the design of buildings with the total ground plan area not exceeding 200 m^2 and the height not exceeding two storeys or 7 m.

9.3.2.3 *Wall index method*

9.3.2.3.1 Wall Index (WI), also known as wall density, shall be used as an indicator of earthquake load-resisting capacity of earthquake resistant design of low-rise buildings with regular plan shape and elevation. The design according to the simplified method shall be deemed satisfactory provided that the actual wall index (WI_{floor}) per floor in each direction of the building plan is greater than or equal to the required Wall Index (WI_{req}) for specific building.

Wall index WI_{floor} at the ground floor shall be taken as ratio of the sum of cross-sectional areas of all confined masonry walls at that level in the considered direction of earthquake shaking, given by:

$$WI_{Floor} = \frac{A_W}{A_p}$$

where

A_w = cross-sectional area of all confined walls in one direction at the ground floor level; the cross-sectional area of a confined masonry wall is the product of its length (including the reinforced concrete tie-columns and the masonry wall) and thickness; and

A_p = plan area of the floor diaphragm (floor slab) at the ground floor level; the area of any cutouts (openings) in the floor slab shall be deducted in the calculation of A_p.

Parameters for wall index calculations are illustrated in Fig. 61. The wall index shall be estimated along each principal plan direction (X and Y) of the building. Only confined masonry walls aligned in the direction under consideration (shown shaded in Fig. 61) shall be considered in the A_w calculations for the specific direction.

9.3.2.3.2 The required wall index WI_{req} in buildings in different earthquake zones shall be taken as per Table 28 or estimated as follows:

$$WI_{\mathrm{req}} \geq \left(\frac{1.5 A_{\mathrm{h}} w}{v_{\mathrm{m}} / \gamma_{\mathrm{m}}}\right),$$

where

A_{h} = design horizontal acceleration coefficient determined as per **5** of Part C/Section 1 of this NBCS for different zones;

n = number of floor levels in a building;

v_{m} = masonry shear strength as per **9.2.2.12**;

γ_{m} = partial safety factor for masonry as per **9.2.2.8**; and

w = average floor weight, including the self-weight of floor slab, floor finish, walls and 25 percent of the imposed load.

9.3.2.4 *Earthquake analysis methods*

Earthquake analysis of confined masonry buildings of four-storey or higher and buildings up to three-storey high that do not meet requirements for the application of simplified method shall be analysed by the method specified in **5** of Part C/Section 1 of this NBCS. Lateral load effects induced by earthquake shall be determined based on the relative stiffness of walls and wall segments, by considering the effect of both shear and flexure in stiffness calculations. The analysis model shall consider stiffness of floor and roof systems, and any other restraints that may influence wall rotations.

9.3.3 *Other Prescriptive Requirements*

9.3.3.1 *Wall spacing*

The maximum spacing of transverse walls in buildings with flexible diaphragms shall not exceed 4 m. For spacing more than 4 m, the tie-beam at roof level should have a width of $L/20$.

9.3.3.2 *Spacing of transverse reinforcement (ties) in tie-columns*

In earthquake zones IV and above reduced tie spacing ($s/2$) shall be provided of the transverse reinforcement at the ends of tie-columns, where s is the spacing of transverse reinforcement specified *in* 9.2.2.13(c) as shown in Fig. 62. The length over which the reduced tie spacing is required shall not exceed the largest of ($2h_c$), ($2t$) and ($h_o/6$), where h_c is the depth of the tie-column, h_o the clear height of tie-column between floors, and t the width of the tie-column.

9.4 General Requirements

9.4.1 *Reinforcement Detailing*

9.4.1.1 *Concrete cover*

a) The minimum concrete cover to ties (transverse reinforcement) in tie-columns and tie-beams shall not be less than 20 mm; and

b) When horizontal wall reinforcement is provided, the minimum clear distance between a horizontal bar and the exterior wall surface shall not be less than 20 mm.

9.4.1.2 *Bar size and number in tie-columns and tie-beams*

Longitudinal reinforcement in tie-columns and tie-beams shall consist of a minimum of 4 reinforcing bars with the minimum 10 mm diameter.

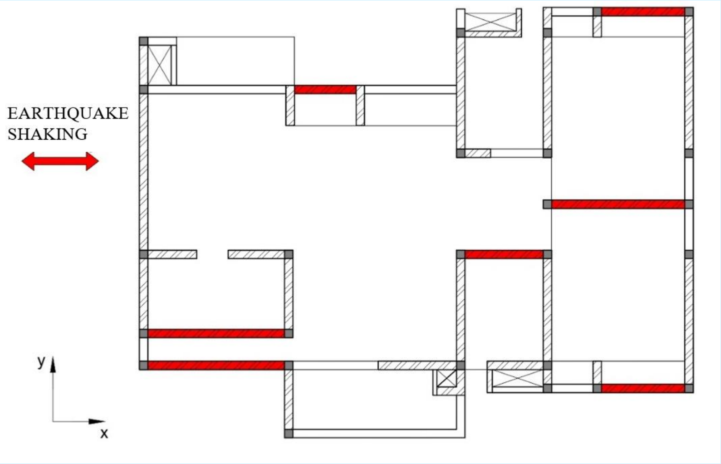

FIG. 61(A) X-DIRECTION

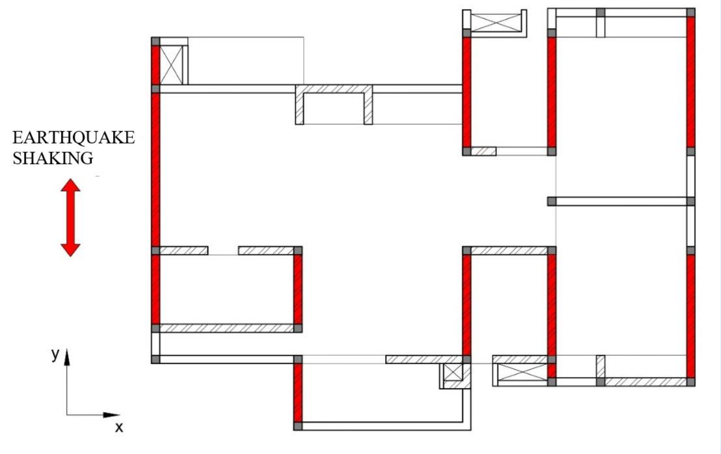

FIG. 61(B) Y-DIRECTION

FIG. 61 WALLS TO BE CONSIDERED IN ESTIMATION OF WALL INDEX ALONG PRINCIPAL PLAN DIRECTIONS OF A BUILDING

(*Clause* 9.3.2.3.2)

Sl No.	Earthquake Zone	II	III	IV	V
(1)	(2)	(3)	(4)	(5)	(6)
i)	WI_{req} (percent)	0.7	1.1	1.6	2.4

9.4.1.3 *Ties in tie-columns and tie-beams*

Minimum 6 mm diameter bars shall be used for ties in tie-columns and tie-beams (Fig. 63). Ties shall have 135° hooked ends. Hooks shall be staggered as shown in Fig. 63.

9.4.1.4 *Anchorage of longitudinal bars*

a) Longitudinal reinforcement in tie-columns and tie-beams shall be anchored to develop the full specified steel yield stress. Longitudinal bars in tie-columns and tie-beams shall have a 90° hooked anchorage at intersections. The lap length of the hook tails shall be the largest of 20 times the bar diameter or 500 mm (Fig. 64); and

b) Tie-column longitudinal bars at the roof level shall be bent by 90° and lapped with the tie-beam longitudinal reinforcement (Fig. 65).

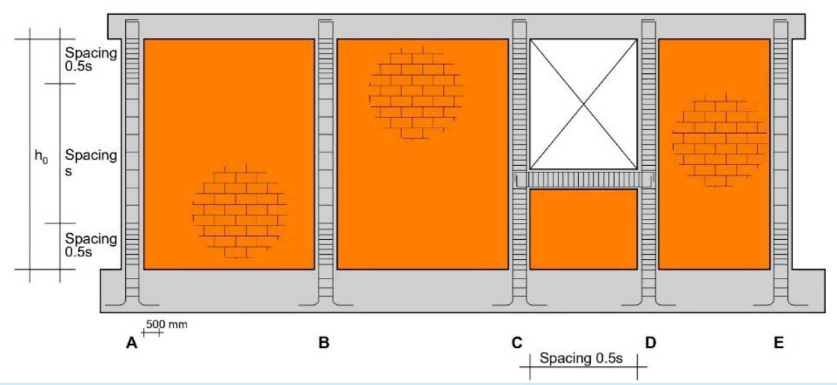

FIG. 62 TIE-COLUMN TRANSVERSE REINFORCEMENT REQUIREMENTS IN EARTHQUAKE ZONES IV AND ABOVE

9.4.1.5 *Lap Splices for longitudinal reinforcement*

Lap splices for longitudinal reinforcement should be at least 40 times the bar diameter. Longitudinal reinforcing bars shall be spliced within the middle third of the column height or beam span. The splices shall be staggered so that not more than 2 bars are spliced at any one location.

9.4.1.6 *Tie-column-to-tie-beam joints*

Continuity of longitudinal tie-beam reinforcement through the joint must be ensured. An example of a continuous longitudinal reinforcement is shown in Fig. 66. First tie at the ends of tie-columns (top and bottom) shall be placed as close to the joint as possible. When tie-beam depth exceeds 300 mm, vertical reinforcement in an RC tie-column must be confined by the ties, below and above the joint. An additional U-shaped stirrup shall be placed in the tie-beam at mid-height (Fig. 67).

Reinforced concrete tie-columns shall be provided at the openings as shown in Fig. 54(B) and Fig. 54(C). A nominal reinforcement around openings as detailed in Fig. 53 shall be provided. When reinforced concrete tie-columns are not provided at the ends of an opening then they should be strengthened as per good practice of [C-4(10)] or minimum two vertical bars of 10 mm diameter with 6 mm ties at 150 mm spacing should be provided.

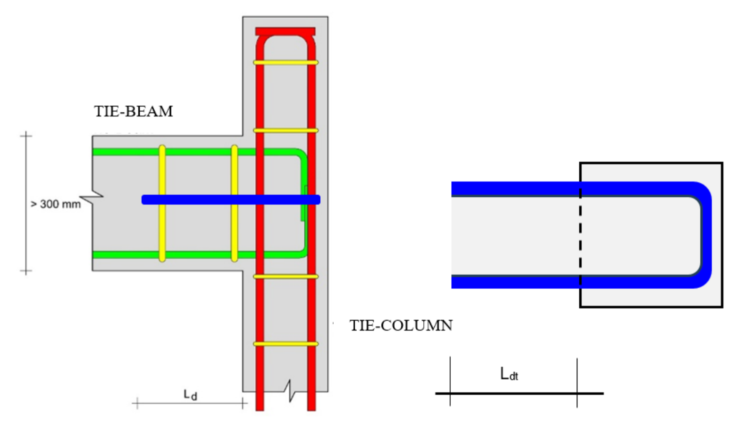

FIG. 67 ADDITIONAL CONFINEMENT OF VERTICAL REINFORCEMENT IN TIE-BEAMS AND TIE-COLUMNS IN EXTERIOR JOINT

9.4.2 *Construction*

Construction of confined masonry buildings shall satisfy the conditions specified hereunder.

9.4.2.1 *Masonry wall construction*

a) *General* — During construction, in addition to the requirements of the sections above, the following shall be complied:

   1) all intersecting walls shall be connected, unless measures to assure stability and good performance are taken;

   2) surfaces of construction joints shall be clean and rough. The joint shall be moistened before construction when clay units are used;

   3) fulfill the requirements of excellent masonry work, Flemish bond or English bond in brickwork shall be adopted; and

4) dring construction, necessary caution to assure wall stability at the job, shall be taken, possible horizontal pressure and loads, including wind and earthquake shall be considered.

b) *Masonry units*

The shape and dimension of masonry units, construction practices, including methods of positioning of reinforcement, placing and compacting of grout, as well as design and detailing shall be, such as to promote homogeneity of structural members, development of the bond between the grout to both reinforcement and masonry units and avoidance of corrosion of reinforcement.

c) *Mortar joint thickness*

Joint mortar shall totally cover the horizontal and vertical sides of the masonry unit. Joint thickness shall be the minimum to get a uniform layer of mortar and good alignment of the units. If industrialized units are used, the thickness of the horizontal joints shall not exceed 12 mm if horizontal reinforcement is placed in the joints, and 10 mm without horizontal reinforcement. Minimum thickness shall be 6 mm.

d) *Toothing*

The vertical interface of masonry with adjacent tie-columns shall be detailed to transfer shear forces. It shall be accepted to indent the masonry (referred to as toothing) or else, to place steel dowels or horizontal reinforcement as shown in Fig. 68.

Toothed edges shall be left on each side of the wall at the interface with the tie-columns. Toothing length shall be equal to one-quarter of the masonry unit length, but not less than 50 mm, as shown in Fig. 68(A). When hand-made bricks are used, it is desirable to cut the brick edges, as shown in Fig. 68(B). It is important to clean the surfaces of 'toothed' masonry units before the concrete has been poured. Horizontal reinforcement anchored into RC tie-columns, also known as dowels, can be used as an alternative no toothing, as shown in Fig. 68(C). The dowels are not necessary when toothed edges are used. 6 mm diameter bars shall be preferably used as dowels.

9.4.2.2 *Reinforcement*

Reinforcement shall be tightly secured before casting.

9.4.2.3 *Concrete*

Casting of tie-columns shall be cast after the masonry wall or the corresponding part has been constructed. The masonry around the tie-columns shall be saturated before the concrete has been poured.

9.4.2.4 *Piping and ducts*

Piping and ducts shall be installed without damaging the masonry. If solid or grouted hollow units are used, grooves in the wall shall be permitted to embed piping and ducts, but the following shall be satisfied:

a) Groove depth shall not exceed one fourth the thickness of the masonry wall ($t/4$);

b) Groove shall be vertical; and

c) Groove shall not be longer than one half the free height of the wall ($H/2$). If hollow units are used, pipes or ducts shall not be placed in cells with reinforcement. Cells with pipes and ducts shall be grouted.

It shall not be permitted to place piping and ducts in tie-columns with a structural function, whether external or internal.

10 REINFORCED MASONRY WALLS (RMW)

10.1 General

The requirements for structural design aspect of reinforced load bearing/walls, constructed with solid or perforated burnt clay bricks, sand-lime bricks, stones, concrete blocks, lime-based blocks or burnt clay hollow blocks shall be specified hereunder related to the materials to be used, the permissible stresses and methods of design.

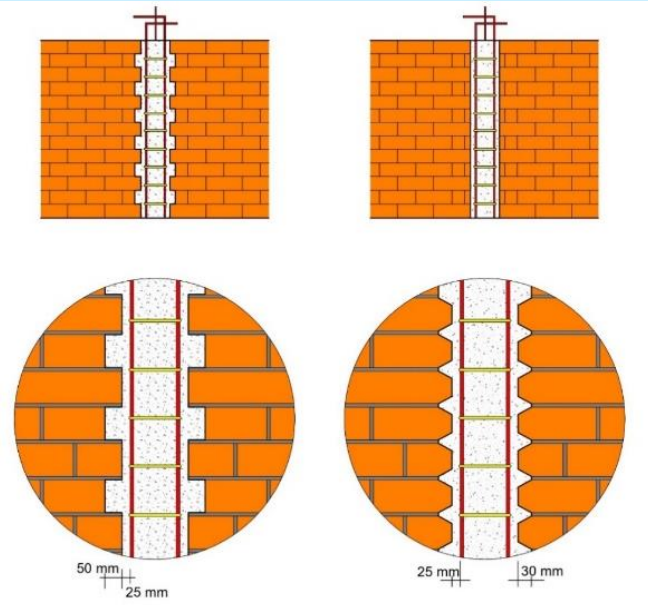

FIG. 68(A) FULL TOOTHING FIG. 68(B) PARTIAL TOOTHING

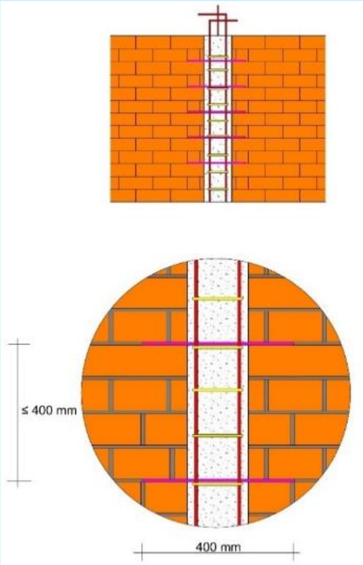

FIG. 68(C) NO TOOTHING

FIG. 68 REINFORCEMENT DETAILS OF TOOTHING IN CONFINED MASONRY WALLS

10.2 Design Considerations

10.2.1 *General*

Design considerations shall be as per geometrical requirements of 4 along with the following provisions.

10.2.2 *Structural Continuity*

Intersecting structural elements intended to act as a unit shall be joined together to resist the design forces. Walls shall be joined together to all floors, roofs or other elements which provide lateral support for the wall. Where floors or roofs are designed to transmit horizontal forces to walls, the anchorages to the walls shall be designed to resist the horizontal forces.

10.2.3 *Effective Span*

10.2.3.1 Effective span of simply supported or continuous members shall be taken as the smaller of the following:

a) Distance between centers of supports; and

b) Clear distance between supports plus an effective depth d.

10.2.3.2 Effective span of a cantilever shall be taken as greater of:

a) distance between the end of cantilever and;

b) centre of its support; and

c) face of support plus half its effective depth.

10.2.4 *Slenderness Ratio*

10.2.4.1 *Wall*

The slenderness ratio (ratio of effective height h_{eff} to effective thickness t_{ef}) shall not exceed 27 for vertically loaded reinforced masonry walls in their plane. For reinforced masonry members, such as walls subjected to out-of-plane bending and for spandrel masonry beams that are a part of wall subjected to bending in the plane of the wall, the maximum effective span to effective depth ratio shall be as given in Table 29.

10.2.4.2 *Columns*

For a column, slenderness ratio shall be taken to be the greater of the ratios of effective heights to the respective effective thickness in the two principal directions. Slenderness ratio for a load bearing unreinforced column shall not exceed 15 whereas for reinforced column the slenderness ratio should be limited to 20.

10.2.5 *Minimum Design Dimensions*

10.2.5.1 *Minimum thickness of load bearing walls columns*

The nominal thickness of masonry bearing walls in building shall not be less than 230 mm.

10.2.5.2 *Parapet wall*

Parapet walls shall be at least 200 mm thick and height shall not exceed 3 times the thickness. The parapet wall shall not be thinner than the wall below. The tie-columns shall be extended into the parapet wall and terminated at the top of the parapet in a tie-beam.

10.2.6 *Eccentricity in Columns*

Columns shall be designed for a minimum eccentricity of 10 percent of side dimension for each axis in addition to applied loads.

10.3 Requirements Governing Reinforcement and Detailing

10.3.1 *General*

This section provides requirements for the working (allowable) stress design of masonry structure neglecting the contribution of tensile strength of masonry.

Table 29 Maximum Ratio Of Effective Span to Effective Depth For Walls Subjected to Out-Of-Plane Bending

(*Clause* 10.2.4.1)

Sl No.	Boundary Conditions	Maximum Permissible Ratios	
		Effective Span to Effective Thickness (l_{ef}/t_{ef}) of Wall Subjected to Out-of-Plane Bending	Effective Span to Effective Depth (l_{ef}/d) of Beam Part of Wall Subjected to In-Plane Bending
(1)	(2)	(3)	(4)
i)	Simply supported	35	20
ii)	Continuous	45	26
iii)	Spanning in 2 directions	45	—
iv)	Cantilevered	18	7

10.3.1.1 Members are designed for composite action. Stresses shall be computed using transformed area concept of linear elastic analysis as follows:

$$A_t = A_b + m\,A_s$$

where

A_t = total transformed cross-sectional area of the member;

A_b = cross sectional area of brick;

m = modular ratio of steel reinforcement and brick; and

A_s = cross sectional area of reinforcement.

10.3.1.2 Stiffness calculation shall be based on un-cracked section properties.

10.3.2 *Steel reinforcement-allowable stresses*

10.3.2.1 *Tension*

Tensile stress in reinforcement shall not exceed the following:

a) 140 MPa in case of Mild Steel (MS) bars of diameter $\leq$ 20 mm and 130 MPa in case of MS bars of diameter > 20 mm; and

b) $0.55f_y$ in case high strength bars, where f_y is the characteristic strength of steel.

10.3.2.2 *Compression*

Compressive stress in reinforcement shall not exceed the following:

a) 130 MPa in case of MS bars; and

b) 190 MPa in case high strength bars.

10.3.3 *Size of Reinforcement*

a) The maximum size of reinforcement used in masonry shall be 25 mm diameter bars and minimum size shall not be less than 8 mm; and

b) The diameter of reinforcement shall not exceed one-half the least clear dimension of the cell, bond beam, or collar joint in which it is placed.

10.3.4 *Spacing of Reinforcement*

a) In beams, clear distance between parallel bars shall not be less than the diameter of the bars, or less than 25 mm; and

b) In columns and pilasters, clear distance between vertical bars shall not be less than 1.5 times the bar diameter, nor less than 35 mm.

10.3.5 *Anchorage*

10.3.5.1 *Development length of bars*

The development length L_{dtm} shall be taken as:

$$L_{\mathrm{dtm}} = \begin{cases} 0.25 d_{\mathrm{b}} F_{\mathrm{s}} \geq 300\ \mathrm{mm} & \text{Fe415, Fe500 and Fe550} \\ 0.40 d_{\mathrm{b}} F_{\mathrm{s}} \geq 300\ \mathrm{mm} & \text{Fe250} \end{cases}$$

where

d_{b} = nominal diameter of bar (mm); and

F_{s} = permissible tensile/compressive stress in steel (MPa).

10.3.5.2 For MS bars, L_d shall be increased by 60 percent.

10.3.5.3 *Standard hooks*

a) Standard hooks shall be formed by one of the following methods (Fig. 69):

1) 180° turn plus extension of at least 4 bar diameters but not less than 64 mm at free end of bar;

2) A 90° turn plus extension of at least 10 bar diameters at free end of bar; and

3) For stirrup and tie anchorage only a 90° or a 135° turn plus an extension of at least 5 bar diameters at the free end of the bar.

b) The diameter of bend, measured to the inside of the bar other than stirrups and ties, shall not be less than 5 bar diameters for 6 mm through 20 mm diameter bars. For 25 mm bars, a minimum bend diameter of 6 times bar diameters shall be used;

c) Inside diameter of bend for 12 mm diameter or smaller stirrups and ties shall not be less than 4 bar diameters. Inside diameter of bend for 16 mm diameter or larger stirrups and ties shall not be less than that given in (b); and

d) Hooks shall not be permitted in the tension portion of any beam, except at the ends of simple or cantilever beams or at the freely supported ends of continuous or restrained beams.

10.3.5.4 *Anchorage of reinforcement*

a) Deformed bars may be used without end anchorages provided development length requirement is satisfied. Hooks should normally be provided for plain bars in tension;

b) Bends and hooks shall conform to the requirements of Part C/Section 5 of this NBCS, and the following anchorage values shall be used:

1) *Bend* — The anchorage value of bend shall be taken as 4 times the diameter of the bar for each 45° bend subject to a maximum of 16 times the diameter of the bar,

2) *Hook* — The anchorage value of a standard U-type hook shall be equal to 16 times the diameter of the bar, and of the 135° hook end equal to 12 times diameter of the bar; and

c) For transverse reinforcement complete development length and anchorage shall be deemed to have been provided when the bar is provided with standard hook as described in **10.3.5.2**.

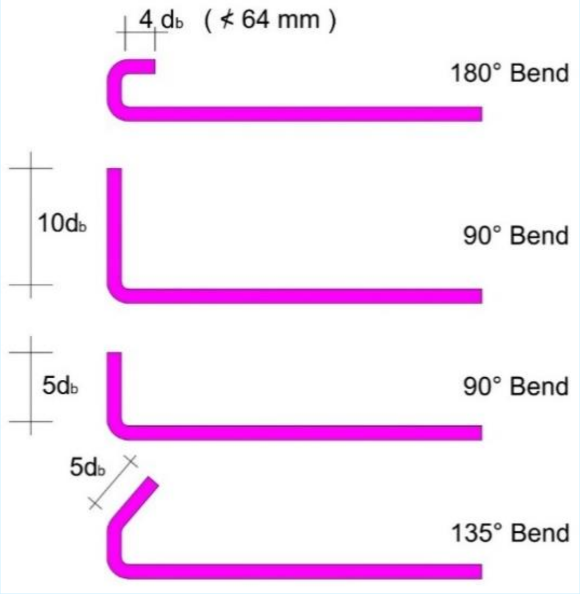

Fig. 69 Standard Hook of a Reinforcing Bar

10.3.6 *Lap Splices*

10.3.6.1 Where splices are provided in the reinforcing bars, they shall as far as possible be away from the sections of maximum stress and be staggered. It is recommended that splices in flexural members not be at sections where the bending moment is more than 50 percent of the moment of resistance; and not more than half the bars shall be spliced at a section. Where more than one-half of the bars are spliced at a section or where splices are made at points of maximum stress, special precautions shall be taken, such as increasing the length of lap and/or using closely spaced stirrups around the length of the splice.

10.3.6.2 Lap length including anchorage value of hooks for bars in flexural tension shall be L_{dtm} (*see* **10.3.5.1**) or $30d_{\mathrm{b}}$ whichever is greater and for direct tension shall be $2L_{\mathrm{dtm}}$ or $30d_{\mathrm{b}}$ whichever is greater. The straight length of the lap shall not be less than $15d_{\mathrm{b}}$ or 200 mm.

10.3.6.3 The following provisions shall also apply:

a) Where lap occurs for a tension bar located at:

   1) top of a section as cast and the minimum cover is less than twice the diameter of the lapped bar, the lap length shall be increased by a factor of 1.4; and

   2) corner of a section and the minimum cover to either face is less than twice the diameter of the lapped bar or where the clear distance between adjacent laps is less than 75 mm or 6 times the diameter of lapped bar, whichever is greater, the lap length should be increased by a factor of 1.4.

b) Where both conditions **10.3.6.3**(a)(1) and **10.3.6.3**(a)(2) apply, the lap length should be increased by a factor of 2.0; and

c) Splices in tension members (which are not part of the lateral force resisting system) shall be enclosed in closed loop hoops made of bars not less than 8 mm diameter with spacing not more than 100 mm.

10.3.7 *Curtailment of Tension Reinforcement*

10.3.7.1 In any member subjected to bending, every reinforcing bar should extend, except at end supports, beyond the point at which it is no longer needed, for a distance equal to the effective depth of the member or 12 times the diameter of the bar, whichever is the greater. The point at which reinforcement is theoretically no longer needed is where the design resistance moment of the section, considering only the continuing bars, is equal to the applied design moment. But, reinforcement should not be curtailed in a tension zone unless at least one of the following conditions is satisfied for all arrangements of design load considered:

a) reinforcing bars extend at least the anchorage length appropriate to their design strength from the point at which they are no longer required to resist bending;

b) design shear capacity at the section where the reinforcement stops are greater than twice the shear force due to design loads, at that section; and

c) continuing reinforcing bars at the section where the reinforcement stops provides double the area required to resist the bending moment at that section.

10.3.7.2 Where there is little or no end fixity for a member in bending, at least 25 percent of the area of the tension reinforcement required at mid-span should be carried through to the support. This reinforcement may be anchored in accordance with **10.3.5.3** or by providing:

a) an effective anchorage length equivalent to 12 times the bar diameter beyond the centre line of the support, where no bend or hook begins before the centre of the support; or

b) an effective anchorage length equivalent to 12 times the bar diameter plus $d/2$ from the face of the support, where d is the effective depth of the member, and no bend begins before $d/2$ inside the face of the support.

Where the distance from the face of a support to the nearer edges of a principal load is less than twice the effective depth, all the main reinforcement in a member subjected to bending should continue to the support and be provided with an anchorage equivalent to 20 times the bar diameter.

10.3.8 *Members Subjected to Flexure and Axial Forces*

10.3.8.1 A member which is subjected to axial stress less than $0.1f_m$, may be designed for bending only.

10.3.8.2 *Beams*

Reinforcement in masonry designed as beams shall provided over a support where the masonry is continuous, whether the beam has been designed as continuous or not. Where this occurs, an area of steel not less than 50 percent of the area of the tension reinforcement required at mid-span shall be provided in the top of the masonry over the support and anchored in accordance with **10.3.5.3**. In all cases, at least one quarter of the reinforcement required at mid-span shall be carried through to the support and similarly anchored.

10.3.8.3 *Columns*

The design of reinforced column shall meet the requirements given hereunder.

10.3.8.3.1 Vertical reinforcement shall not be less than 0.25 percent nor exceed 4 percent of the net area of column cross-section. The minimum number of bars shall be four.

10.3.8.3.2 *Lateral ties*

Lateral ties shall be provided in the column as per the following:

a) Longitudinal reinforcement shall be enclosed by lateral ties of at least 8 mm diameter. Vertical spacing of ties along the length of column shall be minimum of:

   1) 16 times diameter of longitudinal bar;

   2) 48 times diameter of lateral tie; and

   3) Least dimension of the column.

b) Arrangement of lateral ties is such that every corner and alternate longitudinal bar shall have lateral support provided by the corner of a lateral tie with an included angle of not more than 135°.

10.3.9 *Members Subjected to Shear*

10.3.9.1 Reinforced masonry walls may be designed taking contribution of shear reinforcement.

10.3.9.2 Where contribution of shear reinforcement is considered in resisting shear force the minimum area of shear reinforcement in the direction of force shall be determined by the following:

$$A_{v,\min} = \frac{V_s}{F_s d},$$

where

V_s = total applied shear force;

F_s = permissible stress in steel reinforcement as per **10.4.1.4**; and

d = distance from extreme compression fiber to centroid of tension reinforcement.

10.3.9.3 The maximum spacing of shear reinforcement shall not be greater than $0.5d$ or 120 mm, whichever is smaller.

10.3.9.4 In cantilever beams, maximum shear shall be used whereas for members subjected to uniformly distributed load it may be assumed that maximum shear load occurs at a distance of $0.5d$ from the face of support when the following conditions are met:

a) support reaction causes compression in the end region of the member; and

b) no concentrated load between face of support and a distance of $0.5d$ from it.

10.3.10 *Reinforcement Detailing*

10.3.10.1 *General*

Reinforcement shall be located such that it acts compositely with the masonry and various ways in which it can be used in reinforced masonry are shown in Fig. 70.

10.3.10.2 *Protection of reinforcement*

Where steel reinforcing bars are embedded in filled cavity (or pockets) or special bond construction, the bars shall have the minimum clear cover of 10 mm in mortar or a minimum clear cover of 15 mm or bar diameter, whichever is more in cement concrete (grout) so as to achieve good bond and corrosion resistance.

For the reinforcement steel placed in mortar bed joint, the minimum depth of mortar cover from the reinforcing steel to the face of masonry shall be 15 mm. Also mortar cover above and below reinforcement placed in bed joints shall not be less than 2 mm.

Reinforcing steel shall be corrosion resistant or protected adequately against corrosion. Reinforcement shall be galvanized reinforcing steel for protection against corrosion.

10.4 Structural Design

10.4.1 *Permissible Compressive Force*

Compressive force in reinforced masonry due to axial load shall not exceed that given by following equation:

$$P_0 = k_s\left(0.25 f_m A_n + 0.65 f_s A_s\right)$$

Where

k_s = stress reduction factor as per Table 10.

f_m = compressive strength of masonry;

A_n = net area of masonry;

f_s = permissible steel tensile stress; and

A_s = area of steel.

10.4.1.1 *Effective compressive width for locally concentrated reinforcement*

When the reinforcement in masonry is concentrated locally such that it cannot be treated as a flanged member (Fig. 71), the reinforced section shall be considered as having a width of not more than:

a) centre-to-centre bar spacing; and

b) 6 times the wall thickness.

10.4.1.2 *Combined permissible axial and flexural compressive stress*

For reinforced members subjected to combined axial load and flexure, the compressive stress in masonry due to combined action of axial load and bending shall not exceed 1.25f_a and compressive stress in masonry due to axial load only shall not exceed f_a. *See* Annex E.

10.4.1.3 *Permissible tensile stress*

Provisions of **5.4.2** shall apply.

FIG. 71 EFFECTIVE COMPRESSIVE WIDTH

10.4.1.4 *Permissible shear stress*

For members in flexure, the permissible shear stress shall be taken as:

$$f_v = \begin{cases} 0.083\sqrt{f_m} \leq 0.25 \text{ MPa} & \text{Walls without web reinforcement} \\ 0.250\sqrt{f_m} \leq 0.75 \text{ MPa} & \text{Walls with web reinforcement} \end{cases}$$

For walls in compression and bending, the Permissible Shear Stress for reinforced masonry walls shall be according to Table 30.

If there is tension in any part of a section of masonry, the area under tension shall be ignored while estimating the shear stress on the section.

Table 30 Permissible Shear Stress in Reinforced Masonry Walls under Compression and Bending

(*Clause* 10.4.1.4)

Sl No. (1)	Type of Wall (2)	M/Vd (3)	Permissible Shear Stress F_v (Mpa) (4)	Maximum Permissible Shear Stress $F_{v,max}$ (Mpa) (5)

		> 1.0	$0.083\sqrt{f_m}$	0.2
ii)	With web reinforcement	< 1.0	$\frac{1}{24}\left(4 - \frac{M}{Vd}\right)\sqrt{f_m}$	$\left(0.6 - 0.2\frac{M}{Vd}\right)$
		> 1.0	$0.125\sqrt{f_m}$	0.4

10.5 Earthquake Design Requirements

10.5.1 The requirements of this section shall apply to the design and construction of reinforced masonry to improve its performance when subjected to earthquake loads. These provisions are in addition to the general requirements of **5** of Part C/Section 1 of this NBCS. *See* Annex F.

10.5.2 *Different Performance Levels of Masonry Shear Walls*

Masonry buildings rely on masonry shear walls for the lateral load resistance and can be detailed for the following three levels of earthquake performance, which can be appropriately chosen for a building considering its importance, location, and acceptable degree of damage. Table 31 summarizes the requirement for these structural walls and *R* values recommended for use in **5** of Part C/Section 1 of this NBCS.

ii)	RMB 2	Reinforced masonry walls with design reinforcement	As per **10.5.2.2**	All	3.0
iii)	RMB 3	Reinforced masonry walls with special design reinforcement	As per **10.5.2.2** and **10.5.2.3**	All	3.0

10.5.2.1 *Masonry buildings with walls having prescriptive reinforcement* (*RMB* 1)

The design of masonry walls shall comply with requirements of unreinforced masonry wall **4** and those given in **10.5.2.1**(**b**) and **10.5.2.1**(**c**) (*see* Fig. 72).

The requirements of this section apply to the design and construction of reinforced masonry to improve its performance when subjected to earthquake loads. These provisions are in addition to the general requirements of **4**.

a) Elastic force reduction factor R shall be taken as 3 for *Reinforced Masonry Walls*.

b) *Minimum reinforcement requirements* (Fig. 72) — The vertical reinforcement of at least 100 mm^2 in cross-sectional area shall be provided at a maximum spacing of 3 m on centre at the following critical sections:

   1) wall corners;

   2) within 400 mm of each vertical face on either side of the openings extending from plinth to roof or floor level; and

   3) within 200 mm of the vertical end of the walls.

c) *Minimum horizontal reinforcement requirement* — The horizontal reinforcement of at least 100 mm^2 in cross-sectional area shall be provided along the full height of the wall at a maximum centre-to-centre vertical spacing of 400 mm and continuously along the full perimeter of the building, and at the following critical sections:

   1) in bond beam (below window openings and above plinth level in the first storey or floor slab level in the second and higher storeys) and anchoring into the vertical reinforcement provided around the openings;

   2) within 400 mm of each horizontal face above and below of the openings, extending at least 500 mm or $40d_b$ from the vertical face of the openings, where d_b is diameter of the horizontal bar being used; and

   3) within 400 mm of the top of the walls at structurally connected roof and floor levels.

10.5.2.2 *Masonry buildings with walls having design reinforcement* (*RMB* 2)

The masonry walls with design reinforcement shall be designed with the following requirements:

a) requirements specified in **10.1** to **10.4**;

b) elastic force reduction factor (R) shall be taken as 3; and

c) requirements specified in **10.5.2.1**(**b**) and **10.5.2.1**(**c**).

10.5.2.3 *Masonry buildings with walls having special design reinforcement* (*RMB* 3)

Design of special reinforced masonry wall shall comply with the requirement of reinforced masonry as outlined in **10.5.2.2** and the following:

a) The masonry shall be uniformly reinforced in both horizontal and vertical direction such that the sum of reinforcement area in both directions shall be at least 0.2 percent of the gross cross-sectional area of the wall and minimum reinforcement area in each direction shall be not less than 0.07 percent of the gross cross-sectional area of the wall;

b) Maximum spacing of horizontal and vertical reinforcement shall be smaller of:

   1) one-third length of the wall;
   2) one-third height of the wall; and
   3) 1.2 m.

c) Minimum cross-sectional area of reinforcement in vertical direction shall be one-third of the required shear reinforcement placed in horizontal direction; and

d) Shear reinforcement placed in horizontal direction shall be anchored around vertical reinforcing bars with a 135^0 standard hook.

Fig. 72 Requirements of Minimum Reinforcement in Masonry Walls (RMB 1)

11 GUIDELINES FOR IMPROVING EARTHQUAKE RESISTANCE OF LOW STRENGTH MASONRY BUILDINGS

The term 'low strength masonry' includes fired brickwork laid in clay mud mortar and random rubble; uncoursed, undressed or semi-dressed stone masonry in weak mortars; such as cement sand, lime sand and clay mud. Special features of design and construction for improving earthquake resistance of buildings of low strength masonry are given in 11.1 to 11.6.5.7.

11.1 For the purpose of this clause, the terminology given in 8.1 shall apply.

11.2 General Principles

The general principles given in 9.2.1 to 9.2.5 shall be observed in construction of earthquake resistant buildings.

11.2.1 *Lightness*

Since the earthquake force is a function of mass, the weight of the building shall be as minimum as possible, consistent with structural safety and functional requirements. Roofs and upper storeys of buildings, in particular, should be designed as light as possible.

11.2.2 *Continuity of Construction*

11.2.2.1 As far as possible, the parts of the building should be tied together in such a manner that the building acts as one unit.

11.2.2.2 For integral action of building, roof and floor slabs should be continuous throughout as far as possible.

11.2.2.3 Additions and alterations to the structures should be accompanied by the provision of positive measures to establish continuity between the existing and the new construction.

11.2.3 *Projecting and Suspended Parts*

11.2.3.1 Projecting parts should be avoided as far as possible. If the projecting parts cannot be avoided, they should be properly reinforced and firmly tied to the main structure, and their design should be in accordance with good practice [C-4(7)].

NOTE — In cases where stability of projecting parts against overturning is achieved by counterweight in the form of wall, slab, etc, the overturning should be checked by increasing the weight of projecting part and decreasing the weight of stabilizing mass simultaneously in accordance with the vertical seismic coefficient specified in **4.4.2** of good practice [C-4(7)].

11.2.3.2 Ceiling plaster shall preferably be avoided. When it is unavoidable, the plaster shall be as thin as possible.

11.2.3.3 Suspended ceiling shall be avoided as far as possible. Where provided they shall be light, adequately framed and secured.

11.2.4 *Building Configuration*

11.2.4.1 In order to minimise torsion, the building should have a simple rectangular plan and be symmetrical both with respect to mass and rigidity so that the centre of mass and rigidity of the building coincide with each other. It will be desirable to use separate blocks of rectangular shape particularly in seismic zones IV and above.

NOTE — For small buildings, minor asymmetry in plan and elevation may be ignored. Designing such buildings against torsion may be difficult and uncertain.

11.2.5 *Fire Safety*

Fire frequently follows an earthquake and therefore, buildings shall be constructed to make them fire resistant in accordance with the provisions of Part F ‘Fire and Life Safety’ of this NBCS, as relevant.

11.3 Special Construction Features

11.3.1 *Foundations*

11.3.1.1 For the design of foundations, the provisions of Part C/Section 1 and Section 2 of this NBCS shall generally be followed.

11.3.1.2 The subgrade below the entire area of the building shall preferably be of the same type of the soil. Wherever this is not possible, the buildings should preferably be separated into units and then the units should be located separately.

11.3.1.3 Loose fine sand, soft silt and expansive clays should be avoided. If unavoidable, the following measures may be taken to improve the soil on which the foundation of the building may rest:

a) Sand piling/under-reamed piling/stone columns, etc; and

b) Soil stabilization.

11.3.2 *Roofs and Floors*

11.3.2.1 Flat roof or floor should not preferably be made of tiles or ordinary bricks supported on steel, timber or reinforced concrete joists, nor they shall be of a type which in the event of an earthquake is likely to be loosened and parts or all of which may fall. If this type of construction cannot be avoided, the joists should be blocked at ends and bridged at intervals such that their spacing is not altered during an earthquake.

11.3.2.1.1 For pitched roofs, corrugated iron or asbestos sheets should be used in preference to country, Allahabad or Mangalore tiles or other loose roofing units. All roofing materials shall be properly tied to the supporting members. Heavy roofing materials shall generally be avoided.

11.3.2.2 *Pent roofs*

11.3.2.2.1 All roof trusses should be supported on and fixed to timber band, reinforced concrete, or reinforced brick band. The holding down bolts should have adequate size and length as required for earthquake and wind forces.

Where a trussed roof adjoins a masonry gable, the ends of the purlins should be carried on and secured to a plate or bearer which shall be adequately bolted to reinforced concrete or reinforced brick band at the top of gable end masonry.

11.3.2.2.2 At tie level all the trusses and the gable end should be provided with diagonal braces in plan so as to transmit the lateral shear due to earthquake force to the gable walls acting as shear walls.

11.3.2.3 *Jack arches*

Jack arched roofs or floors, where used should be provided with mild steel ties in all spans along with diagonal braces in plan to ensure diaphragm actions.

11.3.3 *Staircases*

11.3.3.1 The inter-connection of the stairs with the adjacent floors should be appropriately treated by providing sliding joints at the stairs to eliminate their bracing effect on the floors. Ladders may be made fixed at one end and freely resting at the other.

11.3.3.2 *Built-in staircase*

When stairs are built monolithically with floors, they can be protected against damage by providing rigid walls at the stair opening. The walls enclosing the staircase, should extend through the entire height of the stairs and to the building foundations.

11.4 Box Type Construction

This type of construction consists of prefabricated or *in-situ* masonry walls along both the axes of the building. The walls support vertical loads and also act as shear walls for horizontal loads acting in any direction. All traditional masonry construction falls under this category. In prefabricated construction attention shall be paid to the connection between wall panels so that transfer of shear between them is ensured.

11.5 Categories of Buildings

For the purpose of specifying the earthquake resisting features in masonry and wooden buildings, the buildings have been categorized in four categories B to E based on the seismic zone and the importance of building I, where I is importance factor applicable to the building, the classification as given in **8.5** shall be applicable. The building categories are given in Table 14.

11.6 Low Strength Masonry Construction

11.6.1 Two types of construction are included herein, namely:

a) Brick construction using weak mortar; and

b) Random rubble and half-dressed stone masonry construction using different mortars such as clay mud, lime-sand and cement sand.

11.6.1.1 These constructions should not be permitted for important buildings and should preferably be avoided for building category D and shall not be used for category E (*see* Table 14).

11.6.1.2 It will be useful to provide damp-proof course at plinth level to stop the rise of pore water into the superstructure.

11.6.1.3 Precautions should be taken to keep the rain water away from soaking into the wall so that the mortar is not softened due to wetness. An effective way is to take out roof projections beyond the walls by about 500 mm.

11.6.1.4 Use of a water-proof plaster on outside face of walls will enhance the life of the building and maintain its strength at the time of earthquake as well.

11.6.1.5 Ignoring tensile strength, free standing walls should be checked against overturning under the action of design seismic coefficient, α_h, allowing for a factor of safety of 1.5.

11.6.2 *Brickwork in Weak Mortars*

11.6.2.1 The fired bricks should have a compressive strength not less than 3.5 MPa. Strength of bricks and wall thickness should be selected for the total building height.

11.6.2.2 The mortar should be lime-sand (1 : 3) or clay mud of good quality. Where horizontal steel is used between courses, cement-sand mortar (1 : 3) should be used with thickness so as to cover the steel with 6 mm mortar above and below it. Where vertical steel is used, the surrounding brickwork of 1 × 1 or 1 ½ × 1 ½ brick size depending on wall thickness should preferably be built using 1 : 6 cement-sand mortar.

11.6.2.3 The minimum wall thickness shall be one brick in one storey construction, and one brick in top storey and 1 ½ brick in bottom storeys of up to three storey construction. It should also not be less than 1/16 of the length of wall between two consecutive perpendicular walls.

11.6.2.4 The height of the building shall be restricted to the following, where each storey height shall not exceed 3.0 m:

a) For Categories B and C: three storeys with flat roof; and two storeys plus attic for pitched roof.

b) For Categories D: two storeys with flat roof; and one storey plus attic for pitched roof.

11.6.2.5 *Special bond in brick walls*

For achieving full strength of masonry, the usual bonds specified for masonry should be followed so that the vertical joints are broken properly from course to course. To obtain full bond between perpendicular walls, it is necessary to make a sloping (stepped) joint by making the corners first to a height of 600 mm and then building the wall in between them. Otherwise the toothed joint should be made in both the walls, alternatively in lifts of about 450 mm (*see* Fig. 20).

11.6.3 *Stone Masonry* (*Random Rubble or Half-Dressed*)

11.6.3.1 The construction of stone masonry of random rubble or dressed stone type should generally follow good practice [C-4(11)].

11.6.3.2 The mortar should be cement-sand (1 : 6), lime sand (1 : 3) or clay mud of good quality.

11.6.3.3 The wall thickness '*t*' should not be larger than 450 mm. Preferably it should be about 350 mm, and the stones on the inner and outer wythes should be interlocked with each other.

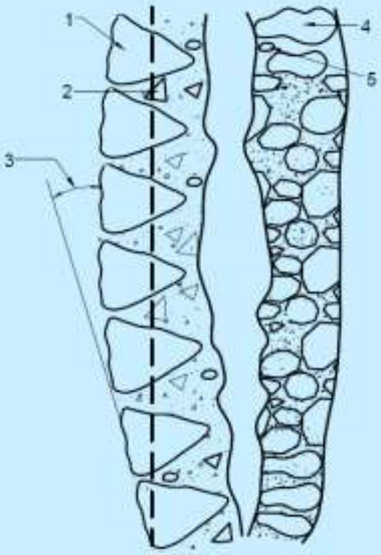
NOTE — If the two wythes are not interlocked, they tend to delaminate during ground shaking, bulge apart (*see* Fig. 73) and buckle separately under vertical load leading to complete collapse of the wall and the building.

11.6.3.4 The masonry should preferably be brought to courses at not more than 600 mm lift.

11.6.3.5 'Through' stones of full length equal to wall thickness should be used in every 600 mm lift at not more than 1.2 m apart horizontally. If full length stones are not available, stones in pairs each of about ¾ of the wall thickness may be used in place of one full length stone so as to provide an overlap between them (*see* Fig. 74).

11.6.3.6 In place of 'through' stones, 'bonding elements' of steel bars 8 mm to 10 mm diameter bent to S-shape or as hooked links may be used with a cover of 25 mm from each face of the wall (*see* Fig. 74). Alternatively, wood bars of 38 mm × 38 mm cross section or concrete bars of 50 mm × 50 mm section with an 8 mm diameter rod placed centrally may be used in place of 'through' stones. The wood should be well treated with preservative so that it is durable against weathering and insect action.

11.6.3.7 Use of 'bonding' elements of adequate length should also be made at corners and junctions of walls to break the vertical joints and provide bonding between perpendicular walls.



1. HALF-DRESSED CONICAL STONE, 2. SMALL ALIGNMENT, 3. ROTATION OF WYTHE, 4. RANDOM RUBBLE, 5. MUD OR WEAK LIME MORTAR.

FIG. 73 WALL DELAMINATED WITH BUCKLED WYTHES

11.6.3.7 Use of 'bonding' elements of adequate length should also be made at corners and junctions of walls to break the vertical joints and provide bonding between perpendicular walls.

11.6.3.8 Height of the stone masonry walls (random rubble or half-dressed) should be restricted as follows, with storey height to be kept 3.0 m maximum, and span of walls between cross walls to be limited to 5.0 m:

a) *For category B* — Two storeys with flat roof or one storey plus attic, if walls are built in lime-sand or mud mortar; and one storey higher if walls are built in cement-sand 1 : 6 mortar; and

b) *For categories C and D* — Two storeys with flat roof or two storeys plus attic for pitched roof, if walls are built in 1 : 6 cement mortar; and one storey with flat roof or one storey plus attic, if walls are built in lime-sand or mud mortar, respectively.

11.6.3.9 If walls longer than 5 m are needed, buttresses may be used at intermediate points not farther apart than 4.0 m. The size of the buttress be kept of uniform thickness. Top width should be equal to the thickness of main wall, *t*, and the base width equal to one sixth of wall height.

11.6.4 *Opening in Bearing Walls*

11.6.4.1 Door and window openings in walls reduce their lateral load resistance and hence should preferably, be small and more centrally located. The size and position of openings shall be as given in Table 32 and Fig. 21.

11.6.4.2 Openings in any storey shall preferably have their top at the same level so that a continuous band could be provided over them including the lintels throughout the building.

11.6.4.3 Where openings do not comply with the guidelines of Table 32, they should be strengthened by providing reinforced concrete lining as shown in Fig. 22 with 2 high strength deformed steel bars of 8 mm diameter.

11.6.4.4 The use of arches to span over the openings is a source of weakness and shall be avoided, otherwise, steel ties should be provided.

FIG. 74 THROUGH STONE AND BAND ELEMENTS

11.6.5 *Seismic Strengthening Arrangements*

11.6.5.1 All buildings to be constructed of masonry shall be strengthened by the methods as specified for various categories of buildings, listed in Table 33 and detailed in subsequent clauses. Fig. 23 and Fig. 24 show, schematically, the overall strengthening arrangements to be adopted for category D buildings, which consist of horizontal bands of reinforcement at critical levels and vertical reinforcing bars at corners and junctions of walls.

11.6.5.2 Lintel band is a band provided at lintel level on all internal and external longitudinal as well as cross walls except partition walls. The details of the band are given in **11.6.5.5**.

11.6.5.3 Roof band is a band provided immediately below the roof or floors. The details of the band are given in **11.6.5.5**. Such a band need not be provided underneath reinforced concrete or reinforced brick slabs resting on bearing walls, provided that the slabs cover the width of end walls fully.

11.6.5.4 Gable band is a band provided at the top of gable masonry below the purlins. The details of the band are given in **11.6.5.5**. This band shall be made continuous with the roof band at the eaves level.

11.6.5.5 *Details of band*

11.6.5.5.1 *Reinforced band*

The band should be made of reinforced concrete of grade not leaner than M15 or reinforced brickwork in cement mortar not leaner than 1 : 3. The bands should be of full width of the wall, not less than 75 mm in depth and should be reinforced with 2 high strength deformed steel bars of 8 mm diameter and held in position by 6 mm diameter bar links, installed at 150 mm apart as shown in Fig. 25.

NOTES

1 In coastal areas, the concrete grade shall be of grade in accordance with Part C/Section 5 of this NBCS and the filling mortar of 1 : 3 ratio (cement- sand) with water proofing admixture.

2 In case of reinforced brickwork, the thickness of joints containing steel bars should be increased to 20 mm so as to have a minimum mortar cover of 6 mm around the bar. In bands of reinforced brickwork, the area of steel provided should be equal to that specified above for reinforced concrete bands.

3 For full integrity of walls at corners and junctions of walls and effective horizontal bending resistance of bands, continuity of reinforcement is essential. The details as shown in Fig. 25 are recommended.

11.6.5.5.2 *Wooden band*

As an alternative to reinforced band, the lintel band could be provided using wood beams in one or two parallel pieces with cross elements as shown in Fig. 75.

11.6.5.6 Plinth band is a band provided at plinth level of walls on top of the foundation wall. This is to be provided where strip footings of masonry (other than reinforced concrete or reinforced masonry) are used and the soil is either soft or uneven in its properties as frequently happens in hill tracts. Where used, its section may be kept same as in **11.6.5.5.1**. This band serves as damp proof course as well.

11.6.5.7 *Vertical reinforcement*

Vertical steel at corners and junctions of walls which are up to 350 mm thick should be provided as specified in Table 34. For walls thicker than 350 mm, the area of the bars should be proportionately increased.

The vertical reinforcement should be properly embedded in the plinth masonry of foundations and roof slab or roof band so as to develop its tensile strength in bond. It should pass through the lintel bands and floor slabs or floor level bands in all storeys. Bars in different storeys may be welded or suitably lapped.

NOTES

1 Typical details of providing vertical steel in brickwork at corners and T-junctions are shown in Fig. 26.

2 For providing vertical bar in stone masonry, use of a casing pipe is recommended around which masonry be built to height of 600 mm (*see* Fig. 53). The pipe is kept loose by rotating it during masonry construction. It is then raised and the cavity below is filled with M15 (or 1 : 2 : 4) grade of concrete mix and rodded to compact it.

NOTES

1 The diameters given above are for high strength deformed bars with yield strength 415 MPa. For mild-steel plain bars, use equivalent diameters.

2 The vertical bars should be covered with concrete of M15 grade or with mortar 1 : 3 (cement-sand) in suitably created pockets around the bars (*see* Fig. 26 and Fig. 76). This will ensure their safety from corrosion and good bond with masonry.

3 For category *B* two storey stone masonry buildings, *see* Note under Table 32.

2. VERTICAL STEEL BAR,
3. CASING PIPE,
4. THROUGH STONE OR BONDING ELEMENT.

FIG. 76 TYPICAL CONSTRUCTION DETAIL FOR INSTALLING VERTICAL STEEL BAR IN RANDOM RUBBLE STONE MASONRY

12 MASONRY WALLS USING RAT-TRAP BOND TECHNOLOGY

This type of masonry shall be applicable for masonry structures of not more than 2 storeys constructed in seismic zones II and III. For buildings in other seismic zones, this type of masonry wall shall be used only in non-load bearing applications such as partition walls. The provisions for this type of masonry shall be as given in Annex G.

13 SUSTAINABILITY IN MASONRY CONSTRUCTION

The sustainability of masonry structures is addressed by quantifying embodied carbon in the structural system and the sources/types of materials used. For guidelines for selection of materials for masonry and assessing the embodied carbon in the masonry systems, the relevant provisions of the relevant guidelines on sustainability may be followed (Handbook on Approach to Sustainability).

14 NOTATIONS AND SYMBOLS

The various notations and letter symbols used in the text of the Section shall have the meaning as given in Annex H.

ANNEX A

(*Clause* 4.7)

SOME GUIDELINES FOR ASSESSMENT OF ECCENTRICITY OF LOADING ON WALLS

A-1 Where a reinforced concrete roof and floor slab of normal span (not exceeding 30 times the thickness of wall) bear on external masonry walls, the point of application of the vertical loading shall be taken to be at the centre of the bearing on the wall. When the span is more than 30 times the thickness of wall, the point of application of the load shall be considered to be displaced from the centre of bearing towards the span of the floor to an extent of one-sixth the bearing width.

A-2 In case of a reinforced concrete slab of normal span (that is, less than 30 times the thickness of the wall), which does not bear on the full width of the wall and 'cover tiles or bricks' are provided on the external face, there is some eccentricity of load. The eccentricity may be assumed to be one-twelfth of the thickness of the wall.

A-3 Eccentricity of load from the roof/floor increases with the increase in flexibility and thus deflection of the slabs. Also, eccentricity of loading increases with the increase in fixity of slabs/beams at supports. Precast RCC slabs are better than *in-situ* slabs in this regard because of very little fixity. If supports are released before further construction on top, fixity is reduced.

A-4 Interior walls carrying continuous floors are assumed to be axially loaded except when carrying very flexible floor or roof systems. The assumption is valid also for interior walls carrying independent slabs spanning from both sides, provided the span of the floor on one side does not exceed that on the other by more than 15 percent. Where the difference is greater, the displacement of the point of application of each floor load shall be taken as one-sixth of its bearing width on the wall and the resultant eccentricity calculated therefrom.

A-5 For timber and other lightweight floors, even for full width bearing on wall, an eccentricity of about one-sixth may be assumed due to deflection. For timber floors with larger spans, that is, more than 30 times the thickness of the wall, eccentricity of one-third the thickness of the wall may be assumed.

A-6 In multi-storeyed buildings, fixity and eccentricity have normally purely local effect and are not cumulative. They just form a constant ripple on the downward increasing axial stress. If the ripple is large, it is likely to be more serious at upper levels where it can cause cracking of walls than lower down where it may or may not cause local over-stressing.

NOTE — The resultant eccentricity of the total loads on a wall at any level may be calculated on the assumption that immediately above a horizontal lateral support, the resultant eccentricity of all the vertical loads above that level is zero.

A-7 For a wall corbel to support some load, the point of application of the load shall be assumed to be at the centre of the bearing on the corbel.

ANNEX B

(*Clauses* 5.4.1 *and* 5.4.5)

CALCULATION OF BASIC COMPRESSIVE STRESS OF MASONRY BY PRISM TEST

B-1 DETERMINATION OF COMPRESSIVE STRENGTH OF MASONRY BY PRISM TEST

When compressive strength of masonry (f_m) is to be established by tests, it shall be done in advance of the construction, using prisms built of similar materials under the same conditions with the same bonding arrangement as for the structure. In building the prisms, moisture content of the units at the time of laying, the consistency of the mortar, the thickness of mortar joints and workmanship shall be the same as will be used in the structure. Assembled specimen shall be at least 400 mm high and shall have a height to thickness ratio (h/t) of at least 2 but not more than 5. If the h/t ratio of the prisms tested is less than 5 in case of brickwork and more than 2 in case of blockwork, compressive strength values indicated by the tests shall be corrected by multiplying with the factor indicated in Table 35.

Table 35 Correction Factors for Different *h*/*t* Ratios

(*Clause* B-1)

Sl No.	Ratio of height to thickness (h/t)	Correction factors for brickwork[1]	Correction factors for blockwork[1]
(1)	(2)	(3)	(4)
i)	2.0	0.73	1.00
ii)	2.5	0.80	—
iii)	3.0	0.86	1.20
iv)	3.5	0.91	—
v)	4.0	0.95	1.30
vi)	5.0	1.00	1.37

[1] Interpolation is valid for intermediate values.

Prisms shall be tested after 28 days between sheets of nominal 4 mm plywood, slightly longer than the bed area of the prism, in a testing machine, the upper platform of which is spherically seated. The load shall be evenly distributed over the whole top and bottom surfaces of the specimen and shall be applied at the rate of 350 kN/m to 700 kN/m. The load at failure should be recorded.

B-2 CALCULATION OF BASIC COMPRESSIVE STRESS

Basic compressive stress of masonry shall be taken to be equal to 0.25 f_m where f_m is the value of compressive strength of masonry as obtained from prism test.

ANNEX C

(*Clauses* 5.3.3 *and* 5.4.1.5)

GUIDELINES FOR DESIGN OF MASONRY SUBJECTED TO CONCENTRATED LOADS

C-1 EXTENT OF DISPERSAL OF CONCENTRATED LOAD

For concentric loading, maximum spread of a concentrated load on a wall may be taken to be equal to b+4t (b is width of bearing and t is thickness of wall), or stretch of wall supporting the load, or centre-to-centre distance between loads, whichever is less.

C-2 INCREASE IN PERMISSIBLE STRESS

C-2.1 When a concentrated load bears on a central strip of wall, not wider than half the thickness of the wall and is concentric, bearing stress in masonry may exceed the permissible compressive stress by 50 percent, provided the area of supporting wall is not less than three times the bearing area.

C-2.2 If the load bears on full thickness of wall and is concentric, 25 percent increase in stress may be allowed.

C-2.3 For loading on central strip wider than half the thickness of the wall but less than full thickness, increase in stress may be worked out by interpolation between values of increase in stresses as given in **C-2.1** and **C-2.2**.

C-2.4 In case concentrated load is from a lintel over an opening, an increase of 50 percent in permissible stress may be taken, provided the supporting area is not less than 3 times the bearing area.

C-3 CRITERIA OF PROVIDING BED BLOCK

C-3.1 If a concentrated load bears on one end of a wall, there is a possibility of masonry in the upper region developing tension. In such a situation, the load should be supported on an RCC bed block (of M20 Grade) capable of taking tension.

C-3.2 When any section of masonry wall is subjected to concentrated as well as uniformly distributed load and resultant stress, computed by making due allowance for increase in stress on account of concentrated load, exceeds the permissible stress in masonry, a concrete bed block (of M20 Grade) should be provided under the load in order to relieve stress in masonry. In concrete, angle of dispersion of concentrated load is taken to be 45° to the vertical.

C-3.3 In case of cantilevers and long span beams supported on masonry walls, indeterminate but very high edge stresses occur at the supports and in such cases it is necessary to relieve stress on masonry by providing concrete bed block of M20 Grade concrete. Similarly when a wall is subjected to a concentrated load from a beam which is not sensibly rigid (for example, a timber beam or an RS joist), a concrete bed block should be provided below the beam in order to avoid high edge stress in the wall because of excessive deflection of the beam.

ANNEX D

(*Clause* 5.5.5)

GUIDELINES FOR APPROXIMATE DESIGN OF NON-LOAD BEARING WALL

D-1 PANEL WALLS

A panel wall may be designed approximately as under, depending upon its support conditions and certain assumptions:

a) when there are narrow tall windows on either side of panel, the panel spans in the vertical direction. Such a panel may be designed for a bending moment of $PH/8$, where P is the total horizontal load on the panel and H is the height between the centres of supports. Panel wall is assumed to be simply supported in the vertical direction;

b) when there are long horizontal windows between top support and the panel, the top edge of the panel is free. In this case, the panel should be considered to be supported on sides and at the bottom, and the bending moment should depend upon height to length ratio of panel and flexural strength of masonry. Approximate values of bending moments in the horizontal direction for this support condition, when ratio (μ) of flexural strength of wall in the vertical direction to that in horizontal direction is assumed to be 0.5, are given in Table 36; and

c) When either there are no window openings or windows are of 'hole-in-wall' type, the panel is considered to be simply supported on all four edges. In this case also, amount of maximum bending moment depends on height to length ratio of panel and ratio (μ) of flexural strength of masonry in vertical direction to that in the horizontal direction. Approximate values for maximum bending moment in the horizontal direction for masonry with $\mu = 0.50$, are given in Table 37.

Table 36 Bending Moments in Laterally Loaded Panel Walls, Free at Top Edge and Supported on Other Three Edges

[*Clause* D-1 (b)]

Sl No.	$\dfrac{\textbf{Height of Panel, } H}{\textbf{Length of Panel, } L}$	**Bending Moment**
(1)	(2)	(3)
i)	0.30	$P.L/25$
ii)	0.50	$P.L/18$
iii)	0.75	$P.L/14$
iv)	1.00	$P.L/12$
v)	1.25	$P.L/11$
vi)	1.50	$P.L/10.5$
vii)	1.75	$P.L/10$

NOTE — For H/L ratio less than 0.30, the panel should be designed as a free-standing wall and for H/L ratio exceeding 1.75, it should be designed as a horizontally spanning member for a bending moment value of $PL/8$.

Table 37 Bending Moments in Laterally Loaded Panel Walls Supported on All Four Edges

[*Clause* D-1 (c)]

Sl No. (1)	$\frac{\text{Height of Panel}, H}{\text{Length of Panel}, L}$ (2)	Bending Moment (3)
viii)	0.30	$P.L/72$
ix)	0.50	$P.L/36$
x)	0.75	$P.L/24$
xi)	1.00	$P.L/18$
xii)	1.25	$P.L/15$
xiii)	1.50	$P.L/13$
xiv)	1.75	$P.L/12$

NOTE — When H/L is less than 0.30, value of bending moment in the horizontal direction may be taken as nil and panel wall may be designed for a bending moment value of $PH/8$ in the vertical direction; when H/L exceeds 1.75, panel may be assumed to be spanning in the horizontal direction and designed for bending moment of $PL/8$.

D-2 CURTAIN WALLS

Curtain walls may be designed as panel walls taking into consideration the actual supporting conditions.

D-3 PARTITION WALLS

D-3.1 These are internal walls usually subjected to much smaller lateral forces. Behaviour of such wall is similar to that of panel wall and these could, therefore, be designed on similar lines. However, in view of smaller lateral loads, ordinarily these could be apportioned empirically as follows:

a) Walls with adequate lateral restraint at both ends but not at the top :
   1) the panel may be of any height, provided the length does not exceed 40 times the thickness;
   2) the panel may be of any length, provided the height does not exceed 15 times the thickness (that is, it may be considered as a free-standing wall); or
   3) where the length of the panel is over 40 times and less than 60 times the thickness, the height plus twice the length may not exceed 135 times the thickness;

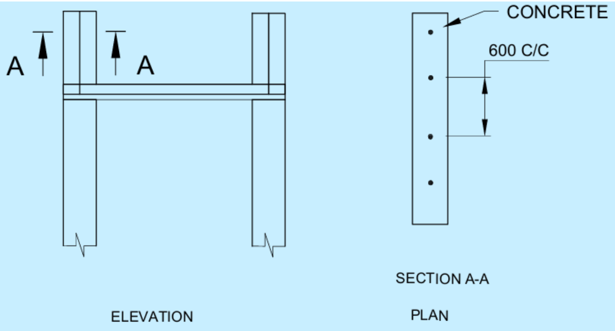
b) Walls with adequate lateral restraint at both ends at the top:
   1) the panel may be of any height, provided the length does not exceed 40 times the thickness;
   2) the panel may be of any length, provided the height does not exceed 30 times the thickness; or
   3) where the length of the panel is over 40 times and less than 110 times the thickness, the length plus three times the height should not exceed 200 times the thickness; and

c) When walls have adequate lateral resistant at the top but not at the ends, the panel may be of any length, provided the height does not exceed 30 times the thickness.

D-3.2 Strength of bricks used in partition walls should not be less than 3.5 N/mm^2 or the strength of masonry units used in adjoining masonry, whichever is less. Grade of mortar should not be leaner than M2.

D-4 CANTILEVER PROJECTIONS

D-4.1 The provisions given under **5** of Part C/Section 1 of this NBCS shall be applicable. As a general guide, the details of connection between parapets and slabs for existing structures shall be as given in Fig. 77.



NOTES

1. HOLE SHALL BE MADE IN BRICKS IN ADVANCE TO ACCOMMODATE THE REINFORCEMENT BARS OF SLAB.
2. BOTTOM BAR OF SLAB CONTINUED IN THE PARAPET AT SPACING OF 600 mm c/c.

FIG. 77 PARAPET WALLS

ANNEX E

(*Clause* 10.4.1.2)

TYPICAL ITERATIVE METHOD FOR WALLS SUBJECTED TO FLEXURE AND AXIAL LOAD

E-1 There is no closed form solution available for the computation of stress in walls due to combined action of bending and axial compression. Engineers normally prefer to use Design charts for computation of stresses in such conditions, but design charts for most masonry systems are not readily available. Therefore, iterative methods are used as most common tools for masonry structures. Two types of iterative procedures are given below, which can be used to analyse the adequacy of the section under specified load and determine the amount of reinforcement required, wherever necessary.

E-2 ITERATIVE PROCEDURE 1

Fig. 78 shows a diagram of a wall subjected to an axial load and bending moment. The same diagram is applicable to both in-plane and out-of-plane bending of walls. There are three possible conditions for the wall:

a) wall is uncracked;

b) wall is cracked with the steel in compression (the extent of the crack has not reached the steel); or

c) wall is cracked with the steel in tension.

Fig. 78 shows the interaction between bending moment and axial load. Loading conditions beyond the limits of the diagram are beyond the allowable stresses. The condition of the wall can be quickly diagnosed by using the non-dimensional parameter M/Pd. This parameter represents a straight line radiating from the diagram's origin as shown in Fig. 79. By summing moments, it can be shown that certain values of M/Pd divide the diagram into three regions. These values are given in Table 38. The allowable moments for regions 1 and 2 can be obtained in closed form with simple equations. But in region 3, it is complicated a bit. The process consists of initial assumption of thickness, length and other necessary parameters and determination of the amount of steel required.

For region 3, the process starts with another assumption that the tension in steel controls. By making an initial guess about the location of the neutral axis, the expressions for M_p and a_2 provide an iterative process that quickly converges. The equations are derived from the summation of forces and moments and by using linear stress-strain relationships. The equations should always converge for all values of P, l_w, M, and n. If convergence is not obtained, it is likely that the assumed initial value of a has exceeded d. The initial value of a is to be reduced and same procedure is to be repeated. The iteration will often result in a negative steel area. This signifies that the element does not need reinforcement to resist the loads within the allowable stresses, even though the section is cracked (region 3).

FIG. 78 FLEXURE AND AXIAL WALL LOADING

Following convergence, a check is made of the initial assumption that tension in steel controls. If not valid, then the compression controls and a new set of equations that do not require iteration are used.

E-3 The following is a detailed step-by-step procedure of the analysis methodology described above:

a) Step 1 — Determine the wall condition:

1) calculate α as the distance from the axial load to the centroid of the tension steel divided by *d*;
2) calculate the quantity M/*Pd*; and
3) use Table 38 to determine the region for analysis. (*see* Fig. 78).

LIMITED BY COMPRESSION
MOMENT (M)

FIG. 79 INTERACTION DIAGRAM

Table 38 Flexure and Axial Loading — Wall Analysis

(*Clauses* E-2 *and* E-3)

Sl No. (1)	Region (2)	Condition of Wall (3)	Test (4)
i)	1	Wall is in compression and not cracked	$\frac{M}{Pd} \leq \left[1 - \frac{l_w}{3d} - \alpha\right]$
ii)	2	Wall is cracked but steel is in compression	$\frac{M}{Pd} \leq \left[\frac{2}{3} - \alpha\right]$
iii)	3	Wall is cracked and steel is in tension	$\frac{M}{Pd} > \left[\frac{2}{3} - \alpha\right]$

b) Step 2 — Calculate the allowable moment:

1) Region 1 — The moment is limited by flexural compression in the masonry;

$$M_m = \frac{b l_w^2}{6} F_b - P \frac{l_w}{6}$$

If M_m is greater than M applied, the section is satisfactory.

2) Region 2 — The moment is also limited by flexural compression in the masonry; and

$$M_m = P(1 - \alpha)d - \frac{2}{3}\left[\frac{P^2}{F_b b}\right]$$

If M_m is greater than M applied, the section is satisfactory.

3) Region 3 — The moment may be limited by either the compression in the masonry or tension in the steel. An iterative approach as below shall be adopted.

   i) Assume a compression centroid location, a; and

   ii) Perform the following iteration that assumes the tension in the steel controls (remember that A_s may be negative).

$$M_p = P\left(\frac{l_w}{2} - \alpha\right)$$

$$A_s = \frac{M - M_p}{F_s(d - a)}$$

$$\zeta = \frac{(P + A_s F_s)n}{F_b b}$$

$$a_2 = \frac{\sqrt{\zeta^2 + 2\zeta d} - \zeta}{3}$$

where

a = estimate of internal compression load centroid distance from the extreme compression fibre;

A_s = area of trim or edge steel;

b = width of the wall for out-of-plane bending (thickness of wall for in-plane bending);

d = distance from the extreme compression fibre to the steel centroid;

F_s = allowable steel tension stress;

I_w = width of the wall for in-plane bending (thickness of wall for out of plane bending);

M = applied moment;

M_p = moment of applied axial load with respect to the centroid of internal compression force; and

P = applied axial load at the centre of the wall.

Use a_2 for a, and repeat until the value of a converges.

c) Step 3 — If the iteration converges and the resulting a is less than the following value, the wall is limited by the tension reinforcement and the analysis is complete. Otherwise continue to step 4:

$$\mathrm{a} = \frac{d}{3\left(1 + \dfrac{F_s/F_b}{n}\right)}$$

d) Step 4 — If the value of a is larger than the above value, determine the required steel area using the following:

$$a = \frac{d}{2} - \sqrt{\left(\frac{d^2}{4} - \frac{2(P\alpha d + M)}{3F_b b}\right)}$$

If $\sqrt{\left(\frac{d^2}{4} - \frac{2(P\alpha d + M)}{3F_b b}\right)}$ is negative, there is inadequate compression capacity.

Increase b or F_b or both. The steel area is:

$$A_s = \frac{\left(\dfrac{3F_b ab}{2} - P\right)}{\left[nF_b\left(\dfrac{d}{3a} - 1\right)\right]}$$

In all cases the wall trim steel should not be less than minimum values.

E-4 ITERATIVE PROCEDURE

The following is another procedure to determine the state of stress in wall elements subjected to combined action of bending and axial compression. Free body diagram of a wall with axial load, bending moment, and tensile and compressive forces is given in Fig. 80. The location of C is based on the neutral axis location kd. The location of T is at the centroid of the reinforcement.

The problem can be solved by taking moments about the centerline of the wall, the tensile reinforcement (assuming that masonry compressive stresses control), or the compressive force (assuming that the stresses in the reinforcement control). By inserting the allowable value of stresses, which is assumed to control, a quadratic equation in terms of kd may be developed and solved.

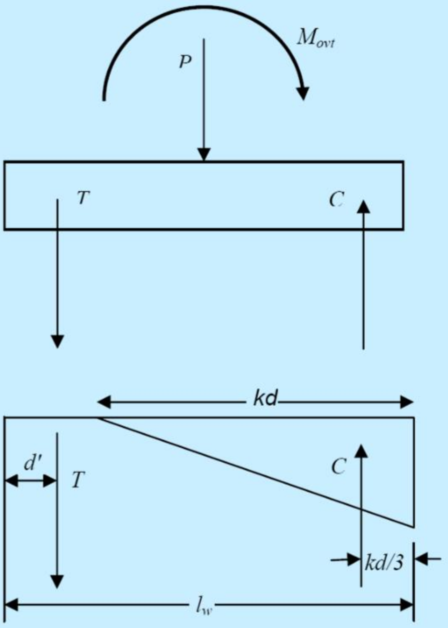

FIG. 80 FLEXURE BODY DIAGRAM OF A WALL

For example if P is at the centerline of the wall, taking moments about the centroid of the tensile reinforcement results in the equation:

$$C\left[\left(l_w - d'\right) - \left(\frac{kd}{3}\right)\right] = P\left(\frac{l_w}{2} - d'\right) + M$$

but $C = \frac{1}{2} F_m bkd$ and $l_w - d' = d$. Then:

$$\frac{1}{2} F_m bkd\left(d - \frac{kd}{3}\right) = P\left(\frac{l_w}{2} - d'\right) + M$$

Dividing both side by $\frac{1}{2} F_m b$ results in

$$kd^2 - \frac{(kd)^2}{3} = \frac{P\left(\frac{l_w}{2} - d'\right) + M}{\frac{1}{2} F_m b}$$

Multiplying by -3 and rearranging terms:

$$(kd)^2 - 3d(kd) + \frac{3\left[P\left(\frac{l_w}{2} - d'\right) + M\right]}{\frac{1}{2} F_m b} = 0$$

$$kd = \frac{3d - \sqrt{(-3d)^2 - 4\left(\frac{3\left[P\left(\frac{l_w}{2} - d'\right) + M\right]}{\frac{1}{2} F_m b}\right)}}{2}$$

Inserting the values for P, M, l_w, b, d and F_m yields kd. Note that this method is iterative since a location of d' shall be assumed.

Having solved for kd one can calculate C.

By $\Sigma F_v = 0$, $T = C - P$

From strain compatibility:

$$f_s = \left(\frac{1-k}{k}\right) nF_m \text{, Thus } f_s \text{ can be calculated.}$$

If $f_s < F_s$, the masonry compressive stress controls and the solution is finished by calculating $A_s = T/f_s$. If however, $f_s > F_s$ the assumption that masonry stresses control is incorrect, and the neutral axis location is wrong.

A good starting assumption to calculate f_m is to take T assuming that masonry compressive stresses control, and to divide by F_s to get a trial A_s. This allows the designer to choose a bar layout and verify the initial assumption of d', the distance to the centroid of reinforcement.

$$A_s = T/F_s$$

Since $C = T + P$ the effects of the axial load can be included by using an effective amount of reinforcement.

$$(A_s)_{\text{eff}} = A_s + \frac{P}{F_s} \; (or \frac{T+P}{F_s})$$

$$\rho_{\text{eff}} = \frac{(A_s)_{\text{eff}}}{bd}$$

$$k = \left[(n\rho)^2 + 2n\rho\right]^{\frac{1}{2}} - n\rho$$

$$j = 1 - \frac{k}{3}$$

The steel stress may be checked using

$$f_s = \frac{M'}{(A_s)_{\text{eff}} \, jd}$$

where

$$M' = P\left(\frac{l_w}{2} - d'\right) + M$$

$$T_{\text{eff}} = (A_s)_{\text{eff}} \times f_s$$

$$T = T_{eff} - P$$

The masonry stress may be checked by using:

$$f_m = \frac{2M'}{bjkd^2}$$

If $f_s > F_s$, a second iteration may be required may be required with a larger bar size or an extra bar. In a shear wall if an extra bar is added, the value of d', and the moments calculated using:

$$P\left(\frac{l_w}{2} - d'\right) + M$$

will need to be re-evaluated. Then one can reiterate from:

$$(A_s)_{\text{eff}} = A_s + \frac{P}{F_s}$$

to reduce f_s so that it is less than F_s.

ANNEX F

(*Clause* 10.5.1)

DISTRIBUTION OF LATERAL FORCES IN THE PIERS OF A MASONRY WALL

F-1 Masonry walls are often seen to be perforated to make arrangement for windows and doors. The distribution of lateral force in a masonry wall is dependent on the position of the openings and the relative rigidity of the masonry piers created due to the presence of the openings in the masonry wall. The relative rigidity is dependent on the height by length ratio (h/L ratio) of the piers and the end conditions of those masonry piers as the deflection of the masonry piers due to horizontal loading changes due to the end condition of the piers (*see* Fig. 81). Here is a simple process is described which can be used to distribute the lateral force in a wall which can be considered to be consist of some piers with some specific arrangements.

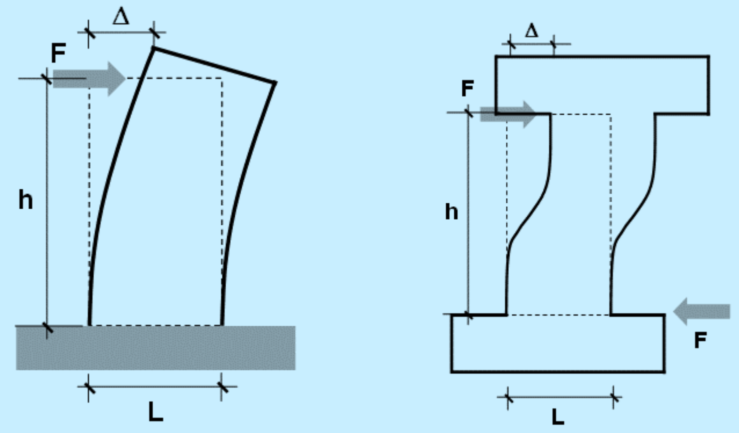

FIG. 81(A) CANTILEVERED WALL OR PIER (TOP FREE TO ROTATE)

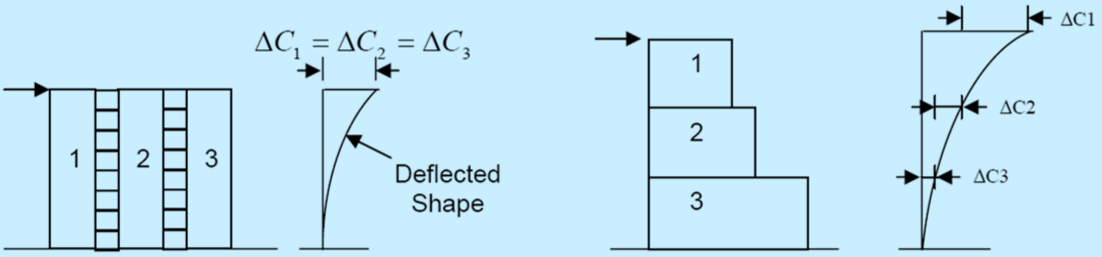
FIG. 81(B) PIER BETWEEN OPENINGS (TOP RESTRAINED FROM ROTATION)

FIG. 81 DEFLECTION DUE TO END CONDITIONS OF PIERS

F-2 In any kind of placing of opening, the wall can be represented as a horizontal and vertical combination of piers with their respective end condition which will be used to find out their rigidities. Where large openings occur, it is difficult to obtain effective coupling of the wall segments or piers. If the wall is analysed as a horizontal combination of piers as shown in the Fig. 82 (a) and the combined rigidity

$$R = R_{c1} + R_{c2} + R_{c3}$$

where R_{c1} , R_{c2} , R_{c3} are the rigidities of the piers 1, 2, 3, respectively.



(a) HORIZONTAL COMBINATION OF WALL SEGMENTS

(b) VERTICAL COMBINATION OF WALL SEGMENTS

FIG. 82 WALL COMBINATIONS FOR CALCULATING RIGIDITIES OF WALLS WITH OPENINGS

If the segments are combined vertically, as shown in Fig. 82 (b), the combined rigidity can be calculated as:

$$R = \frac{1}{\Delta C_1 + \Delta C_2 + \Delta C_3} = \frac{1}{\dfrac{1}{R_{c1}} + \dfrac{1}{R_{c2}} + \dfrac{1}{R_{c3}}}$$

Where R_{c1}, R_{c2} , R_{c3} are the rigidities of the piers 1, 2, 3 respectively. Combination of these two types can be used to find the effective relative stiffness of a masonry wall.

The expression ignores the rotations that occur at the tops of segment 2 and 3 and therefore overestimates the rigidity of the wall. Along with this, it is valid only for the application of loads at the top level of the building.

As already said the rigidity R of the pier is dependent on its dimensions, modulus of elasticity E, modulus of rigidity G, and the support conditions. For a cantilever pier the displacement due to combined action of bending and shear is

$$\Delta_c = \frac{Fh^3}{3EI} + \frac{1.2Fh}{GA}$$

where

A = area of the pier = Lt;

F = horizontal force applied to the pier;

G = modulus of Rigidity = $0.4E_m$;

h = height of the pier;

I = moment of inertia of pier = $tL^3/12$;

L = length of the pier; and

t = thickness of pier.

So, displacement of the cantilever pier is:

$$\Delta C = \frac{1}{Et}\left[4\left(\frac{h}{L}\right)^3 + 3\left(\frac{h}{L}\right)\right]$$

The rigidity of a wall is proportional to the inverse of the deflection. For cantilever walls the rigidity will be:

$$R_c = \frac{1}{\Delta C} = \frac{Et}{\left[4\left(\frac{h}{L}\right)^3 + 3\left(\frac{h}{L}\right)\right]}$$

$$\Rightarrow \frac{R_c}{Et} = \frac{1}{\left[4\left(\frac{h}{L}\right)^3 + 3\left(\frac{h}{L}\right)\right]}$$

For a pier with both ends fixed against rotation the deflection due to combined action of bending and shear will be:

$$\Delta f = \frac{Fh^3}{12EI} + \frac{1.2Fh}{GA} = \frac{F}{Et}\left[\left(\frac{h}{L}\right)^3 + 3\left(\frac{h}{L}\right)\right]$$

$$\Rightarrow \frac{R_f}{E_t} = \frac{1}{\left[\left(\frac{h}{L}\right)^3 + 3\left(\frac{h}{L}\right)\right]}$$

Values of R/E_t for different h/L ratio can be taken from the chart in the Fig. 83.

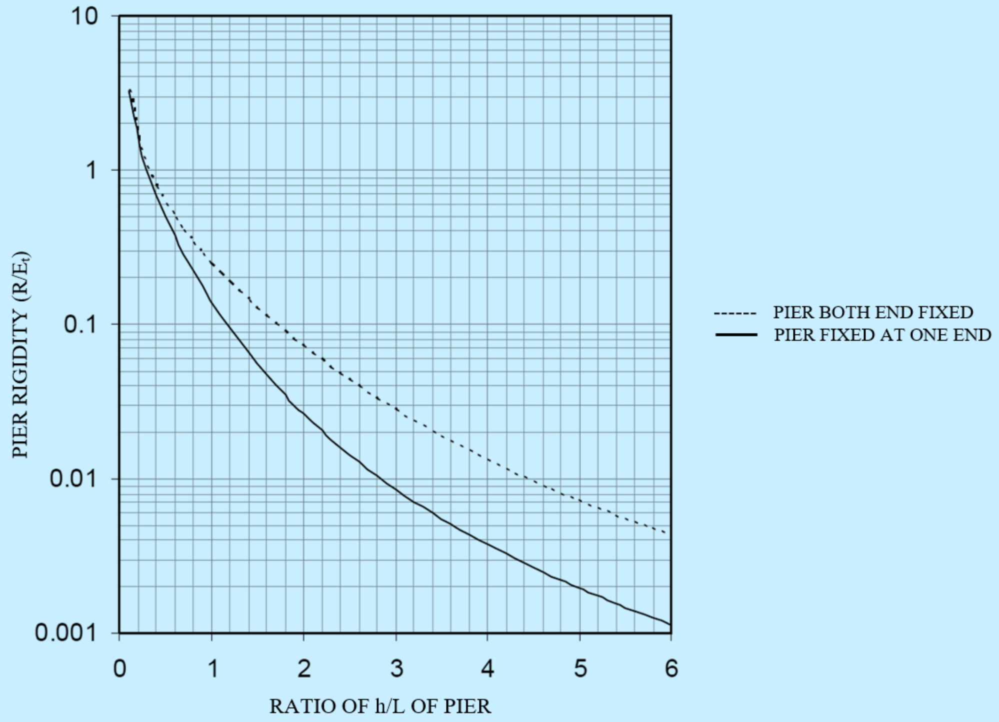


FIG. 83 CHARTS FOR CALCULATING WALL RIGIDITIES

From the relations given in equations above it is found that the relative contributions of the bending and shear deformation depend on the wall aspect ratio (*h/L*) and therefore, the rigidity varies over the height of the building. For high *h/L* ratios, the effect of shear deformation is very small and calculation of pier rigidities based on flexural stiffness is relatively accurate. For very squat walls (with *h/L< 0.25*), rigidities based on shear deformation are reasonably accurate, but for intermediate walls with *h*/*L* from 0.25 to 4, both components of relative rigidity should be considered.

F-3 The method is explained further explained by one illustration. For the wall as shown in Fig. 84.

$$R_{\text{wall}} = \frac{1}{\Delta_{1c} + \Delta_{2,3,4,5,6(\text{f})}} = \frac{1}{\dfrac{1}{R_{1c}} + \dfrac{1}{R_{2,3,4,5,6(\text{f})}}} \quad \text{(Vertical combination)}$$

where

$$R_{2,3,4,5,6(f)} = R_{2(f)} + R_{3,4,5,6(f)} \quad \text{(Horizonta l combination)}$$

$$\text{and } R_{3,4,5,6(f)} = \frac{1}{\Delta_{3,4,5(\text{f})} + \Delta_{6(\text{f})}} = \frac{1}{\dfrac{1}{R_{3,4,5(\text{f})}} + \dfrac{1}{R_{6(\text{f})}}} \quad \text{(Vertical combination)}$$

$$R_{3,4,5(\text{f})} = R_{3(\text{f})} + R_{3(\text{f})} + R_{3(\text{f})} \text{ (Horizontal combination)}$$

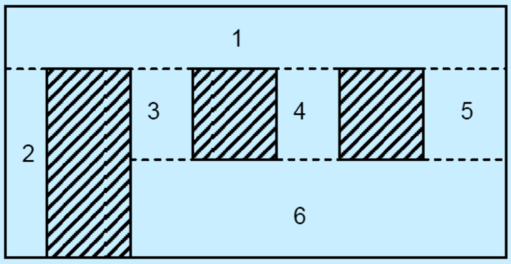

FIG. 84 WALL WITH OPENINGS (CALCULATION OF RIGIDITY AND LOAD DISTRIBUTION)

ANNEX G

(*Clause* 12)

MASONRY WALLS USING RAT-TRAP BOND

G-1 GENERAL

The following covers the construction of masonry walls using rat-trap bond. Only masonry with bricks (burnt clay bricks, fly ash-clay bricks, fly ash-lime bricks and stabilized soil blocks) is dealt herein. Use of other types of bricks/blocks and mud mortar are not specifically covered hereunder.

G-2 NECESSARY INFORMATION

G-2.1 For efficient planning, design and execution of the work, detailed information with regard to the following shall be furnished to those responsible for the work:

a) layout plans showing the orientation of the structure;

b) dimensioned details of the structure with details of sections (to a suitably large scale that is 1 : 20), levels of foundation, finished ground level, clear floor to floor heights of rooms, sizes of openings, etc;

c) type and class of brickwork, types of bond and final finish for the brickwork; the mixes of mortar to be used, etc, full size details of architectural features, mouldings and other special work. Also course plans at different levels of sill and lintel to be made available for proper understanding and execution, if required; and

d) location and other details of openings, chases, embedment of service lines, such as for water supply, drainage, electrical installations, etc, and location and details of hearths, flues and chimneys in the brickwork.

G-2.2 All information as in **G-2.1** shall be made available to those who are responsible for the masonry work. Necessary drawings and instructions for planning the work shall be furnished. Arrangements shall also be made for the proper exchange of information between those engaged in masonry work and all those whose work will affect or will be affected.

NOTE — If necessary a brief training of the masons may be carried out orienting them with the technology know-how.

G-3 MATERIALS

G-3.1 Bricks

Burnt-clay bricks, heavy duty bricks and bricks made out of other suitable materials like fly ash, stabilized soil block, etc, conforming to accepted standards [C-4(12)] with compressive strength greater than 6.0 MPa shall be used.

G-3.2 Mortars

Shall conform to grade H2 mortar for good practice [C-4(3)].

G-3.3 Storage of Materials

Storage of materials shall be in accordance with good practice [C-4(2)].

G-3.4 Materials for Damp-Proof Courses

Materials for damp proof courses shall be as specified in [C-4(5)].

G-3.5 Materials for Flashing and Weathering

Lead flashing with sheet thickness between 1.6 mm and 2 mm or bitumen felts shall be in accordance with the accepted standards [C-4(13)].

G-3.6 Metal Reinforcement

Metal reinforcement for use in brick masonry shall be as per accepted standards [C-4(14)].

G-4 DESIGN CONSIDERATIONS

G-4.1 Selection of Bricks

The brick shall be selected in accordance with Table 1 of good practice [C-4(4)].

When the requirements for strength of masonry predominate in the particular situation of use, the bricks shall be of such class to give the required strength for masonry and shall be selected in accordance with **4**.

G-4.2 Rat-Trap Bond Details

G-4.2.1 The rat-trap bond is laid by placing the bricks on edge forming a cavity of 80 mm (for a traditional brick size) with alternate course of stretchers and headers (Fig. 85). The headers and stretchers are staggered in subsequent layers to impart strength and stability to the walls.

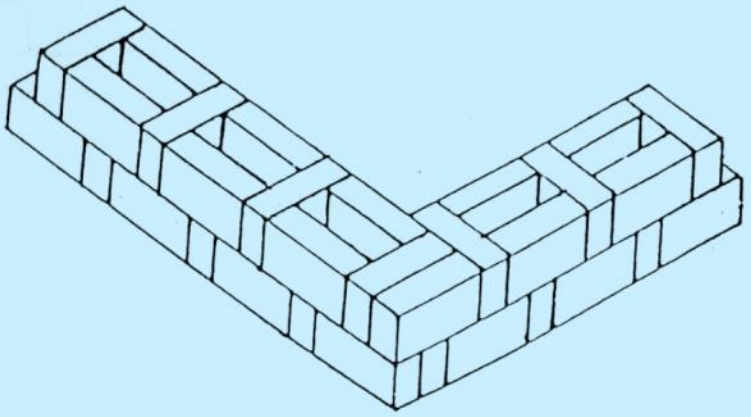

FIG. 85 ARRANGEMENT IN RAT-TRAP BOND

The primary object of bond is to give strength to masonry, but when exposed, it also creates aesthetically pleasing view. This masonry technology is modular in nature, so the dimensions of the wall to be based on the module dimensions in multiples.

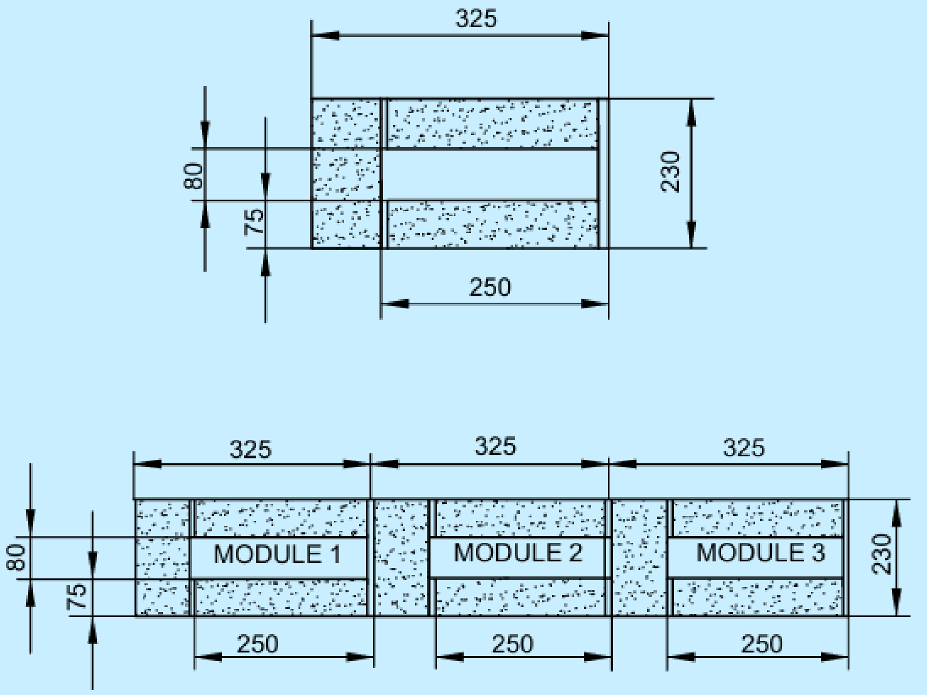
G-4.2.2 A typical module detail is shown in Fig. 86 with conventional bricks of size 230 mm × 110 mm × 75 mm. The brick adjacent to the openings has to be solid as per Fig. 87. So, the opening dimensions also to be in multiple of the rat-trap bond module. This will be important as opening dimensions are predefined depending on the module dimension. In brickwork the cross joints in any course shall not be nearer than a quarter of brick length from those in the course below or above it.

G-4.3 Precautions

This type of masonry construction shall have to be carried out by trained masons to avoid wastage of mortar falling into the gap. Rat-trap bond shall never be carried out with brick which are below their minimum strength requirements.

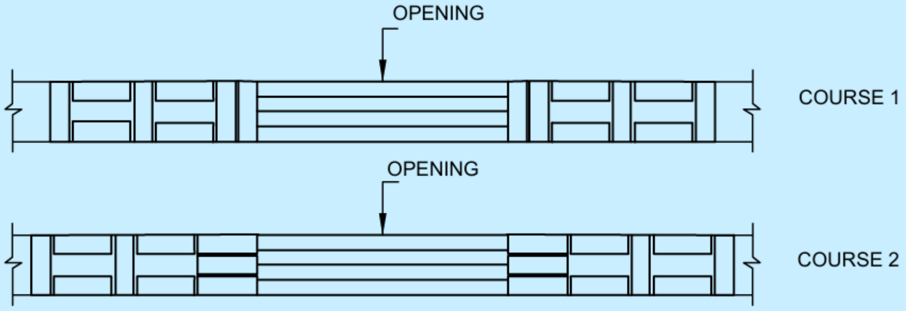
G-4.4 Strength of Rat-Trap Bond

The compressive strength of rat-trap bond will be different from that of solid wall of similar thickness. Rat-trap bond wall provides continuous cavity over the entire wall height and hence it is convenient to reinforce if necessary to resist lateral loads. The compressive strength of the unreinforced rat-trap bond wall can be determined either based on the cavity wall design guidelines following **5.5.1.2** or the basic compressive stress can be assessed following the tests on prism specimen given at **G-7**.



PLAN

FIG. 86 TYPICAL MODULE DETAILS OF RAT-TRAP BOND



PLAN

FIG. 87 OPENING IN RAT-TRAP BOND MASONRY

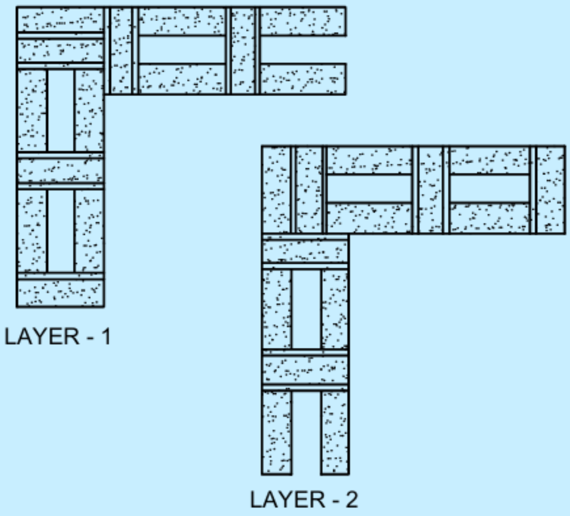
G-4.5 Thickness of Joint

No bed joint shall be thicker than 12 mm. Further the thickness of the bed joints shall be such that four courses and three joints taken consecutively shall measure as follows:

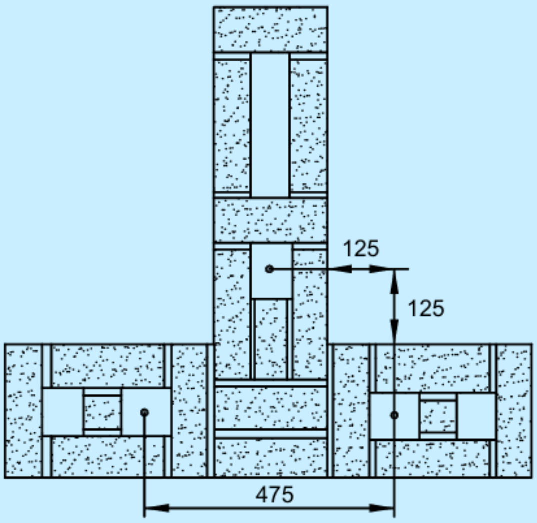
a) *In the case of traditional bricks* — Four times the actual thickness of the brick plus 30 mm.;

b) *In the case of modular bricks* — 390 mm conforming to the relevant accepted standards. The vertical mortar joints to be of the thickness of 10 mm and be applied directly to the brick before placing it. This requires some special skill, but defines the strength as well as the stability of the Rat-trap bond wall. Besides, applying the mortar joint directly to the brick is a basic skill requirement of a mason and determines the speed of work and finally the cost of the Rat-trap bond wall; and

c) The *face* jolts of brickwork may be finished by 'jointing' or by 'pointing'. In case where brick size is less, the elevation of the header bricks to be made even in line with the stretcher brick by cement mortar same grade as bedding mortar. The main reasons for pointing the surface of block or brickwork joints are to increase its weather resistance and to give a neat finish to the work. Pointing can be carried out as construction of the brickwork proceeds, using ordinary mortar in which the bricks are bedded.



L - JUNCTION DETAIL FOR ALTERNATE LAYERS



All dimensions in millimetres.

FIG. 88 TYPICAL LAYING OF RAT-TRAP BOND

G-4.6 Structural and Functional Characteristics of Brickwork

G-4.6.1 *Structural Stability and Strength*

Reference may be made to Part C/Section 2 of this NBCS, and 4 of this Section.

G-4.6.2 *Resistance to Moisture Penetration*

The suitability of various walls under different conditions of exposure is indicated in Table 3 of good practice [C-4(4)].

G-4.6.3 *Thermal Stresses*

The coefficient linear expansions of brick vary from $5 \times 10^{-6}/°C$ to $11 \times 10^{-6}/°C$. Variations of temperature tend to produce linear changes in walls which, when restrained, may lead to internal stress resulting in cracks especially when the walls exceed 30 m. The effects of these stresses shall be taken into consideration for a proper design.

G-4.7 Control of Shrinkage Cracking

G-4.7.1 To confine cracks to the joints and to dissipate these into a large number of fine joints, it is desirable that the mortar used shall be weaker than the bricks.

G-4.7.2 Cracking due to shrinkage normally will occur at openings or other points where the vertical or horizontal section of a wall changes. A long wall with a few openings will tend to show wider cracks above and below the openings than a similar wall with many openings. Metal reinforcement may be embedded in brickwork at points where cracking is likely to occur.

G-4.8 Thermal Insulation

For requirements of thermal insulation in walls, the provisions of good practice [C-4(15)] shall apply.

G-4.9 Fire Resistance

For requirements regarding resistance to fire, the provisions of good practice [C-4(16)] shall apply.

G-4.10 Sound Insulation

Requirements for insulation against airborne sound are laid down in good practice [C-4(17)] shall apply.

G-5 LAYING OF BRICKWORK

G-5.1 Brick shall be laid on a full bed of mortar. When laying the bricks, it shall be slightly pressed so that the mortar gets into all the pores of the brick surface to ensure proper adhesion. Cross joints and wall joints shall be properly flushed and packed with mortar so that no hollow spaces are left. Properly filled joints ensure maximum strength and resistance to penetration of moisture which takes place mainly through joints.

G-5.2 The following specific guidelines shall be followed:

a) In areas with a very high ground water table, it is advisable to build the first 4 to 5 courses of the wall, with either English or a Flemish bond. This is to avoid ground and spill water related dampness problems;

b) Always clean the surface where the first layer of bricks is to be laid, which is usually above the plinth level;

c) Arrange the joints between the bricks in such a way that only full bricks (shiners) fit. Ensure that the bonding is correct;

d) To properly maintain the brick cross, lay the first two masonry courses by marking mark each of the shiner and the header bricks at the centre;

e) Place the shiner/stretcher and header brick now in such a way that the marks are exactly matching. The remaining courses may then be laid to match with the first two courses;

f) Spread a full bed of mortar, and furrow it with a trowel. This will ensure that plenty of mortar is on the bottom of the bricks for the first course;

g) Lay the corner bricks first. Carefully position the corner bricks first. Be sure to lay all bricks with the frog inside the cavity of the wall in order to create an aesthetically pleasing outer wall surface;

h) The vertical mortar joints shall be applied directly to the brick before placing it. This requires some special skill, but defines the strength as well as the stability of the rat-trap bond wall;

j) The maximum rat-trap bond brick wall height per day should not exceed more than 9 layers; and

k) Cavities of rat-trap bond shall be closed for the first course after damp proof course, below sill level, below and above lintel and at the top most course; this can be made by a layer of headers or headers.

G-5.3 Protection Against Damage

Care shall be taken during construction that edges of jambs, sills, heads, etc are not damaged. In inclement weather, newly built work shall be covered with gunny bags or tarpaulin so as to prevent the mortar from being washed away.

G-6 INSPECTION

G-6.1 General

The object of inspection of brick masonry work is to ensure its satisfactory performance and also to ascertain whether all the recommended practice of workmanship is adopted at every stage. As the correct strength of masonry cannot be ascertained without destruction, a close supervision during the course of construction is necessary to ensure satisfactory performance. The strength of brickwork depends on the strength of individual brick, strength of mortar, bond and workmanship.

G-6.2 Inspection of Materials

In case of large works, samples of bricks, sands, *Surkhi*, lime, cement, etc, which goes to form the brickwork, shall be periodically tested in a laboratory to make sure that they conform to the requirements stated in **G-3**. Simple field tests may suffice in the case of small works.

G-6.3 Inspection of Workmanship

A close supervision while the work is in progress will ensure a better quality work with the materials available for use. The following shall be observed at the time of inspection:

a) all loose materials, dirt and set lumps of mortar which may be lying over the surface over which brickwork is to be freshly started, shall be removed with a wire brush;

b) all the bricks shall be thoroughly soaked in potable water before use;

c) the surface over which the brickwork is to be started shall be made moist;

d) plastic mortar results in thorough bedding of the brick and more complete filling of the joints which ensure greater strength. Care shall be taken to see that the required quantity of water is added to the mortar at the mixing platform itself and not over the courses;

e) all the joints shall, as far as possible, be thin and the specifications mentioned in **G-4.5** in this regard shall be strictly adhered to;

f) care shall be taken to see that there is no through joints and the lap is not less than half the width of the brick, and that all the vertical joints are properly filled with mortar;

g) the verticality of the walls and horizontality of the courses shall be checked very often with plumb bob and spirit level respectively;

h) no portion of the work shall be left more than 1 m lower than the other. Where the masonry of one part has to be delayed the work shall be ‘raked back’ suitably at an angle not exceeding 45° according to bond and not toothed;

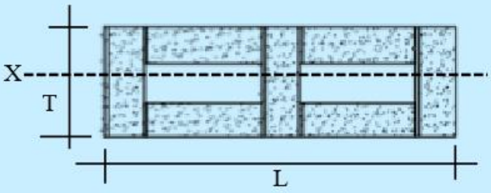
j) where plastering is required to be done all the vertical as well as horizontal joints shall be raked to a depth of about 10 mm while the mortar is wet, and this will ensure satisfactory adhesion between the plaster and brickwork; and

k) care shall be taken to ensure that the brick work is kept wet for first seven days using appropriate curing methods.

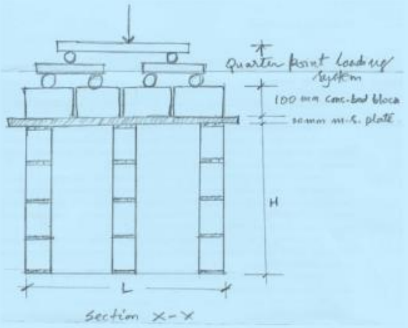
G-7 TESTING METHOD FOR RAT-TRAP BOND WALL SAMPLES

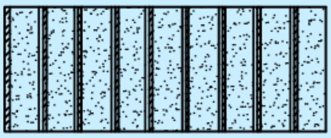
G-7.1 A Prism specimen as shown in Fig. 89 shall be used. The prism specimen should have similar mortar and bricks/blocks as that to be used in the rat-trap bond wall of the structure. The prism height (H) to width (T) ratio should be between 2 and 5 and based on H/T ratio the prism strength should be corrected following the correction factors given in **B-1** for blockwork.

The number of prism specimens to be tested and the necessary correction factors to be applied to derive modified compressive strength of the prism shall be ascertained following the procedure given in **5.4**. The modified mean prism compressive strength shall be divided by 4 (as per **B-2**) to assess the basic compressive stress for the rat-trap bond wall, which can be used in calculating the compressive strength of rat-rap bond masonry wall. A similar test as above should be done in an English bond per coupon (*see* Fig. 90).

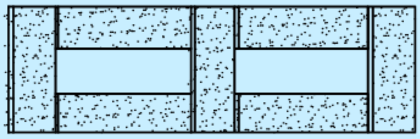


Plan of the Prism

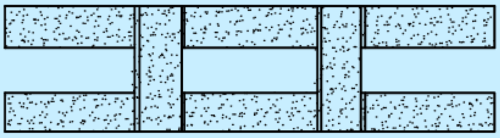




LAYER 0 AND 5



LAYER 1 AND 3



LAYER 2 AND 4

FIG. 89 PRISM SIZE AND LOADING ARRANGEMENT FOR THE RAT-TRAP BOND PRISM SPECIMEN

G-7.2 The load on rat-trap bond specimen should be not less than 85 percent of the load capacity of English bond wall compressive strength.

G-7.3 While designing the compressive stress on rat-trap bond wall, it should be ensured that the stress is not more than 0.85 of that of solid wall as per **4** of this Section.

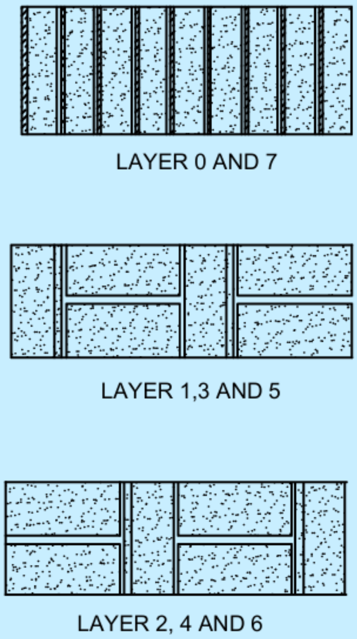


FIG. 90 ENGLISH BOND TEST SPECIMEN

ANNEX H

(*Clause* 14)

NOTATIONS, SYMBOLS AND ABBREVIATIONS

H-1 The following notations, letter symbols and abbreviations shall have the meaning indicated against each, unless otherwise specified in the text of this Section of this NBCS:

A = Area of a section

b = Width of bearing

DPC = Damp proof course

e = Resultant eccentricity

f_b = Basic compressive stress

f_c = Permissible compressive stress

f_d = Compressive stress due to dead loads

f_s = Permissible shear stress

f_m = Compressive strength of masonry (in prism test)

GL = Ground level
H = Actual height between lateral supports
H' = Height of opening
$H1$, $H2$ = High strength mortars
h = Effective height between lateral supports
k_a = Area factor
k_p = Shape modification factor
k_s = Stress reduction factor
L = Actual length of wall
$L1$, $L2$ = Lower strength mortars
$M1$, $M2$ = Medium strength mortars
P = Total horizontal load
PL = Plinth level
RCC = Reinforced cement concrete
RS = Rolled steel
S_p = Spacing of piers/buttresses/cross walls
SR = Slenderness ratio
t = Actual thickness
t_p = Thickness of pier
t_w = Thickness of wall
W = Resultant load
W_1 = Axial load
W_2 = Eccentric load
w_p = Width of piers/buttresses/cross walls
μ = Ratio of flexural strength of wall in the vertical direction to that in the horizontal direction

LIST OF STANDARDS

The following list records those standards which are acceptable as ‘good practice’ and ‘accepted standards’ in the fulfilment of the requirements of this NBCS. The latest version of a standard shall be adopted at the time of enforcement of this NBCS. The standards listed may be used by as a guide in conformance with the requirements of the referred clauses in this NBCS.

In the following list, the number appearing in the first column within parentheses indicates the number of the reference in this Section.

	IS No.	*Title*
(1)	IS 1077 : 2025	Common burnt clay building bricks — Specification (*sixth revision*)
	IS 1725 : 2023	Specification for stabilized soil blocks used in general building construction (*third revision*)
	IS 2180 : 1988	Specification for heavy duty burnt clay building bricks (*third revision*)
	IS 2185	Concrete masonry units — Specification:

National Building Code Sectional Committee, CED 46

FOREWORD

This NBCS (Part C/Section 5) covers the structural design aspects of plain and reinforced concrete and also the prestressed concrete.

This Section 5 was first published in 1970 having Subsections 5A 'Plain and reinforced concrete' and 5B 'Prestressed concrete' of SP 7 (Part 6) and were subsequently revised in 1983, 2005 and 2016 as a chapter of National Building Code of India.

This Section is largely based on IS 456 : 2000 'Code of practice for plain and reinforced concrete (*fourth revision*)' and IS 1343 : 2012 'Prestressed concrete — Code of practice (*second revision*)' both of which are currently under revision and are being merged in the fifth revision of IS 456, likely to be titled as 'Structural concrete — Code of practice' at the time of the publication of this NBCS.

Major changes have been envisaged in the revision of IS 456 (amalgamating IS 1343). In the absence of availability of finalized version of revised IS 456, at the time of the revision of this publication, the provision of design as per existing IS 456 : 2000 and IS 1343 : 2012 have been continued through appropriate reference to the same.

In the 2016 version of the Code, in addition to the provisions of IS 456, provisions relating to special concrete namely self-compacting concrete, high performance concrete and steel fibre reinforced concrete were introduced.

In this revision, the publication has been renamed as National Building Construction Standards (NBCS).

In this fourth revision of this Section, Subsections 5A and 5B have been merged into a single Section 5, 'Structural concrete', and the following additional changes are made:

a) Special concretes, namely self-compacting concrete**,** high-performance concrete, and steel fibre reinforced concrete, which were earlier covered in **16A**, **16B** and Annex A of the erstwhile NBC, are now included in Annex B, Annex C, and Annex D respectively;

b) Informative Annex (Annex A) on updated provisions regarding materials for making concrete is introduced;

c) Criteria for structural safety of tall concrete buildings is introduced in Annex E. This provides prescriptive requirements for design of reinforced concrete tall buildings. The following salient aspects, which are based on the prescriptive approach, are addressed in the Annex E:

    1) Structural systems admissible for tall building in different seismic zones;

    2) General requirements including: (i) height limitations of different structural systems, (ii) elevation and plan aspect ratios, (iii) lateral drift, (iv) storey stiffness and strength, (v) modes of vibration, (vi) floor systems, (vii) materials, and (viii) progressive collapse mechanism;

    3) Wind and seismic effects: (i) load combinations, and (ii) acceptable serviceability criteria for lateral accelerations;

    4) Methods of structural analysis to be adopted, and section properties (in cracked and uncracked states) of reinforced concrete member to be considered in analysis;

    5) Structural design aspects for various applicable structural systems;

    6) Issues to be considered in design of foundations; and

    7) Systems needed for structural health monitoring.

The upcoming fifth revision of IS 456 introduces a holistic design philosophy that emphasizes that concrete structures shall not only be strong but also safe, durable, serviceable under expected loads, and resilient in the face of extreme and accidental events. To this end, the standard stipulates that structural design shall meet six design criteria that are strength, serviceability, durability, robustness, integrity, and restorability. Each of these criteria is associated with performance objectives and corresponding design requirements, ensuring that structural behaviour is assessed comprehensively across its entire lifecycle, including performance during and after any adverse events.

The design philosophy outlined in the above revised standard includes the classification of the design process into the prescriptive process and the closed-loop process. The prescriptive process follows conventional rule-based checks and is applicable to structures where only the basic three criteria (strength, serviceability, and durability) are of concern. In contrast, the closed-loop process is intended for important or critical structures and involves a more rigorous approach, requiring not only quantitative compliance for the first three criteria but also qualitative and performance-based verification for robustness, integrity, and restorability. This two-tier approach introduces flexibility in application while ensuring that safety and resilience are not compromised, especially in vital infrastructure. By integrating modern concerns like post-disaster repairability (restorability), progressive collapse prevention (integrity), and resistance to accidental actions (robustness), the design philosophy ensures that structures are not just built to withstand known demands but also prepared for uncertainties. It promotes reliability, sustainability, and long-term performance.

The revision of IS 456 highlights that structural analysis should correctly capture how structures behave under all types of loads, including static, dynamic, and accidental forces. For regular structures, linear static analysis is generally sufficient. However, for structures affected by dynamic forces like earthquakes, wind, or machine vibrations, dynamic analysis is necessary. In critical cases, the standard also recommends using non-linear dynamic analysis to better reflect the actual behaviour of materials and structures. This approach moves towards more detailed and performance-based analysis to improve safety, serviceability, durability, and resilience in concrete structures.

Apart from drawing from IS 456 : 2000 and IS 1343 : 2012, this revision incorporates provision relating to tall concrete buildings, drawn from IS 16700 : 2023 ‘Criteria for structural safety of tall concrete buildings (*first revision*)’.

All standards, whether given herein above or cross-referred to in the main text of this Section, are subject to the revision. The parties to agreement based on this Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

As the regulation of land development and buildings is a State subject and is dealt by the States and local bodies such as urban local bodies within their jurisdiction through building regulatory documents like building regulations, building byelaws, and fire regulations, this document is voluntary in nature and is non-binding. The implementation depends on adoption by concerned parties or stipulations in a contract or by appropriate adoption by the concerned authorities.

For the purpose of deciding whether a particular requirement of this Subsection is complied with, the final value, observed or calculated, expressing the result of a test or analysis, shall be rounded off in accordance with IS 2 : 2022 ‘Rules for rounding off numerical values (*second revision*)’. The number of significant places retained in the rounded off value should be the same as that of the specified value in this section.

Important Explanatory Note for Users of the NBCS

In any Part/Section of this NBCS, where reference is made to **'good practice'** in relation to design, constructional procedures or other related information, and where reference is made to **'accepted standard'** in relation to material specification, testing, or other related information, the Indian Standards listed at the end of the Part/Section shall be used as a guide to the interpretation.

At the time of publication, the editions indicated in the standards were valid. All standards are subject to revision and parties to agreements based on any Part/ Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

In the list of standards given at the end of a Part/Section, the number appearing within parentheses in the first column indicates the number of the reference of the standard in the Part/Section. For example:

a) Good practice [C-5(2)] refers to the Indian Standard(s) give at serial number (2) of the list of standards given at the end of this Part C/Section 5, that is, IS 456 : 2000 'Plain and reinforced concrete — Code of practice (*fourth revision*)'.

b) Accepted standard [C-5(4)] refers to the Indian Standard(s) give at serial number (4) of the list of standards given at the end of this Part C/Section 5, that is, IS 269 : 2015 'Ordinary Portland cement — Specification (*sixth revision*)'.

NATIONAL BUILDING CONSTRUCTION STANDARDS

PART C STRUCTURAL DESIGN

SECTION 5 STRUCTURAL CONCRETE

1 SCOPE

This NBCS (Part C/Section 5) deals with the structural use of plain, reinforced, and prestressed concrete.

2 TERMINOLOGY

For the purpose of this Section, the definitions given in accepted standards [C-5(1)] shall apply.

3 MATERIALS

All materials used in plain, reinforced and prestressed concrete construction shall conform to Part B 'Building Materials' of this NBCS as available.

4 STRUCTRAL DESIGN USING PLAIN, REINFORCED AND PRESTRESSED CONCRETE

The provision relating to design and general structural use of plain, reinforced and prestressed concrete, including on:

a) materials, including special concrete, workmanship, inspection and testing;

b) general design consideration;

c) special design requirements for structural members and systems; and

d) structural design: limit state method.

shall be in accordance with good practices contained in section 2, section 3, section 4 and section 5 of the good practice [C-5(2)] and section 2, section 3 and section 4 of the good practice [C-5(3)].

> NOTE — At the time of publication of this section, IS 456 and IS 1343 were under revision, with IS 1343 being amalgamated into IS 456. Once the revised IS 456 is published, it shall replace the provisions given in **4**.

The informative Annex A to this Section suggests the updated list of materials and few tests. Users are encouraged to investigate the possibility of applying the provisions given in Annex A which are listed in consonance with the provisions regarding materials in the good practice [C-5(2)].

5 STRUCTURAL SAFETY OF TALL REINFORCED CONCRETE (RC) BUILDINGS

For criteria for structural safety of tall reinforced concrete (RC) buildings of heights greater than 50 m and less than 250 m, normally intended for use as residential, office and other commercial buildings, reference may be made to Annex E and accepted standard [C-5(4)].

6 EARTHQUAKE RESISTANT DESIGN AND DETAILING OF STRUCTURES

The provisions on earthquake-resistant design and detailing of concrete buildings are covered in [C-5(5)].

ANNEX A

(*Foreword and Clause 4*)

MATERIALS FOR MAKING CONCRETE

A-1 AGGREGATES

A-1.1 Normal Weight Aggregates

Aggregates derived from natural sources and other than natural sources (manufactured aggregates such as iron slag, copper slag, bottom ash from thermal power plants, recycled concrete aggregates and recycled aggregates), shall comply with the requirements of the accepted standard [C-5(6)]. These are natural or synthetic aggregates with in-place density (unit weight) between 22.40 kN/m^3 to 27.00 kN/m^3.

A-1.2 Heavyweight Aggregates

Natural or synthetic aggregates with in-place density (unit weight) more than 27.00 kN/m^3 and can range up to 45.00 kN/m^3 for aggregates other than steel. Steel aggregates (if used) will have further higher density. Heavy weight aggregate is most commonly used for radiation shielding, counterweights and other applications where a high mass-to-volume ratio is desired. Goethite, limonite, barite, illmenite, magnetite, hematite, ferrophosphorus and steel are some examples of heavy weight aggregate.

A-1.3 Lightweight Aggregates

Natural or synthetic with in-place density (unit weight) between 14.40 kN/m^3 to 18.40 kN/m^3. The lightweight is due to the cellular or high internal porous structure, which gives this type of aggregate a low specific gravity. The most important aspect of lightweight aggregate is the porosity. They have high absorption values, which requires a modified approach to concrete proportioning. Light weight aggregates namely sintered fly ash aggregates may be used for making light weight structural concrete (a type of special concrete). Sintered flyash coarse aggregates when used shall conform to the accepted standard [C-5(7)].

A-2 CEMENT

A-2.1 For general use in plain, reinforced and prestressed concrete construction, cement used shall be any of the following and the type selected should be appropriate for the intended use:

a) Ordinary Portland cement conforming to the accepted standard [C-5(8)];

b) Portland slag cement conforming to the accepted standard [C-5(9)];

c) Portland pozzolana cement (fly ash based) and Portland pozzolana cement (calcined clay based), conforming to the accepted standard [C-5(10)];

d) Composite cement conforming to the accepted standard [C-5(11)] and containing a declared clinker content not less than 45 percent, fly ash content not more than 25 percent and a minimum 28-day compressive strength of 43 MPa can be used for reinforced concrete construction; and

e) Portland calcined clay limestone cement conforming to the accepted standard [C-5(12)]. At locations where temperatures are predominantly below 15 °C for 6 months, the use of Portland calcined clay limestone cement shall not be permitted in underground structures and structural elements in contact with ground water.

A-2.2 Other cements as given below can be used for specific applications:

a) Sulphate resisting portland cement conforming to the accepted standard [C-5(13)];

b) Microfine ordinary portland cement conforming to the accepted standard [C-5(14)];

c) Hydrophobic cement conforming to the accepted standard [C-5(15)];

d) Low heat Portland cement conforming to the accepted standard [C-5(16)];

e) Rapid-hardening portland cement conforming to the accepted standard [C-5(17)];

f) High alumina cement conforming to the accepted standard [C-5(18)];

g) Supersulphated cement conforming to the accepted standard [C-5(19)]; and

h) White cement conforming to the accepted standard [C-5(20)].

A-3 WATER

A-3.1 Water used for mixing and curing shall be clean and free from excessive amounts of total dissolved solids (TDS), oils, acids, alkalis, salts, sugar, organic materials or other substances that may be deleterious to steel and setting and strength development of concrete.

A-3.2 Types of Water

In general, the suitability of water for the production of concrete depends upon its origin. Water to be used for mixing and curing of concrete shall be any of the types described below. Any type of water to be used for mixing and curing shall be tested as per stated procedures and shall meet all the requirements given in **A-3.3**.

A-3.2.1 *Potable Water*

This water is considered as suitable for use in concrete if meeting the requirements of the accepted standard [C-5(21)] wherein the chloride content shall be limited to 500 PPM and alkalinity is less than or equal to 25 ml (**A-3.3**). Such water needs no further testing. In case of any doubt it shall be tested for conformity according to **A-3.3**.

A-3.2.2 *Natural Surface Water*

This water, if found suitable, can be used in concrete but shall satisfy the requirements of **A-3.3**.

A-3.2.3 *Treated Water*

Appropriately treated water, conforming to **A-3.3**, from industrial, municipal and other sources can be used in concrete.

A-3.2.4 *Water Recovered from Processes in the Concrete Industry*

This includes:

a) water that was part of surplus concrete;

b) water used to clean the inside of the stationery mixers, mixing drums of truck mixer or agitators and concrete pumps; and

c) process water from sawing, grinding and water blasting of hardened concrete.

This water may be taken from:

1) Basins provided with suitable equipment that distributes the solid matter evenly throughout the water; and

2) Sedimentation basins or similar installations, provided the water is left in the basin for a sufficient amount of time to allow the solids to settle properly.

Water recovered from process in the concrete industry contains varying concentrations of very fine particles, the size of which is generally less than 0.25 mm. Water recovered from processes in the concrete industry or combined water can be used provided the following requirements are met:

i) The additional mass of solid material in the concrete resulting from the use of water recovered from processes in the concrete industry shall be less than 1 percent mass fraction of the total mass of aggregates present in the concrete; and

ii) The amount of recovered water shall be spread as evenly as possible over a day's production.

A-3.2.5 *Water from Other Sources*

A-3.2.5.1 *Recycled water*

This includes water recovered from concrete production operation or water generated from sewage, greywater or storm water systems and treated to a standard that is appropriate for its intended use.

A-3.2.5.2 *Desalinated water*

Desalinated water conforming to **A-3.3** can be used. However normal sea water or brackish water shall not be used for mixing of concrete because of presence of harmful salts.

A-3.3 Requirements for Preliminary Inspection of Mixing and Curing Water

A-3.3.1 *Preliminary Inspection*

The water shall be examined for oil and fats, detergents, colour, suspended matter, odour and humic matter shall meet the requirements given in Table 1 in accordance with test procedures stated below.

A small subsample shall be assessed as soon as possible after sampling. Bring any material that has settled back into suspension by shaking the sample. Pour 80 ml of the sample into a 100 ml measuring cylinder. Seal with a suitable stopper and shake the cylinder vigorously for 30 s. Smell the sample for any odours other than those of clean water. If in doubt about the odour, test the water for its odour level in accordance with national regulations for potable water. The odour level of the water shall be lower than the maximum level accepted for potable water. Observe the surface for foam. Set the cylinder in a place free from vibration and allow to stand for 30 min. After 2 min, check the sample for the continuing presence of foam and signs of any oils or fats. After 30 min have elapsed, observe the apparent volume of the settled solids and the colour of the water. Measure the pH using indicator paper or a *p*H metre. Then, add 0.5 ml hydrochloric acid, mix and then smell or test for the presence of hydrogen sulphide.

Put 5 ml of the sample into a test tube. Bring it to a temperature between 15 °C and 25 °C by allowing it to stand indoors. Add 5 ml of 3 percent sodium hydroxide solution, shake and leave for 1 h. Observe the colour.

Table 1 Requirements for Preliminary Inspection of Mixing Water

(*Clause* A-3.3.1)

Sl No. (1)	Parameter (2)	Requirements (3)
i)	Oils and fats	Not more than visible traces
ii)	Detergents	Any foam should disappear within 2 min
iii)	Colour	Water not from sources classified as potable: the colour shall be assessed qualitatively as pale yellow or pale
iv)	Odour	Water from sources classified as potable: no smell, except the odour allowed for potable water and a slight smell of cement; where blast-furnace slag is present in the water, a slight smell of hydrogen sulphide Water from other sources: no smell, except the odour allowed for potable water; no smell of hydrogen sulphide after addition of hydrochloric acid
v)	*p*H value	6.0 to 8.5
vi)	Humic matter	The colour shall be assessed qualitatively as yellowish/brown or paler after addition of NaOH

A-3.3.2 Permissible limits for solids shall be as given in Table 2.

Table 2 Maximum Permissible Limit for Solids for Mixing and Curing Water

(*Clauses* A-3.3.2 *and* A-3.4)

Sl No.	**Parameter**	**Tested as per Accepted Standard**	**Maximum Permissible Limit**	
			For Mixing Water	For Curing Water
(1)	(2)	(3)	(4)	(5)
i)	Organic	[C-5(22)]	200 mg/l	200 mg/l
ii)	Inorganic	[C-5(22)]	3 000 mg/l	3 000 mg/l
iii)	Sulphate (as SO_3^-)	[C-5(23)]	400 mg/l	800 mg/l
iv)	Chloride (as Cl^-)	[C-5(24)]	2 000 mg/l for concrete not containing embedded steel and 500 mg/l for reinforced concrete work[1]	500[1] mg/l for reinforced concrete or prestressed concrete work and 2 000 mg/l for concrete not containing embedded steel
v)	Suspended matter	[C-5(25)]	2 000 mg/l	2 000 mg/l

[1] 1 000 mg/l chloride in water for reinforced concrete work (but not for prestressed concrete) can be permitted provided the chloride content of hardened concrete is checked at the time of concrete mix design and conform to requirement of total chloride content in the concrete.

A-3.4 Testing and Requirements of Curing Water

Permissible limits for solids shall be as given in Table 2. Water used for curing should not produce any objectionable stain or unsightly deposition on the concrete surface. The presence of tannic acid or iron compounds is objectionable.

A-3.5 Sampling of Water Concrete Making and Curing

A sample of water not less than 5 litre shall be taken. The sample of water taken for testing shall represent the water proposed to be used for concreting with due account being paid to seasonal variation. The sample shall be stored in a clean container previously rinsed out with similar water.

A-4 ADMIXTURES

A-4.1 Admixtures can be used to:

a) Alter the composition of concrete by replacing some of the cement in the concrete by pozzolanic and hydraulic reaction (and are called mineral admixtures or supplementary cementitious materials);

b) Enhance a certain function of concrete (and are called chemical admixtures); and

c) The following types of admixtures shall be used in production of concrete.

A-4.2 Mineral Admixtures/Supplementary Cementitious Materials (SCMs)

SCMs as given below may be used as part replacement of cement. They can be pozzolanic material or reactive mineral admixture or combination of both.

A-4.2.1 *Fly Ash* (*Pulverized Fuel Ash*)

Fly ash conforming to the accepted standard [C-5(26)] may be used as part replacement of ordinary Portland cement. For concrete having steel, the replacement level of fly ash shall be restricted to 35 percent by weight of cementitious material wherein fly ash shall have a minimum fineness of 280 m^2/kg and lime reactivity of 4.5 N/mm^2 or more.

A-4.2.2 *Silica Fume*

Silica fume conforming to the accepted standard [C-5(27)] may be used as part replacement of cement. Silica fume is usually used in proportion of 3 percent to 10 percent of the cementitious content of a mix. The total replacement by fly ash and silica fume shall not be more than 35 percent for reinforced cement concrete. The total replacement by GGBF slag and silica fume/Ultrafine ground granulated blast furnace slag (UFGBS) shall not be more than 60 percent for reinforced cement concrete.

The above limits shall also apply where PPC or PSC is used. The fly ash or slag content mentioned on the bag shall be considered.

Only for mass concrete, structures below ground (not exposed to atmosphere) and for plain concrete, the use of more than one type of mineral admixture with ordinary Portland cement or a mineral admixture with blended cements such as PPC and PSC can be permitted after necessary trials (to control heat of hydration). However, silica fume may be used as an additional mineral admixture in reinforced concrete subjected to limits specified above. Uniform blending of the mineral admixtures with the cement should be ensured. In such cases, fly ash and GGBS together may be used within following limits:

Total replacement (*Max*) = 45 percent of total cementitious content
Fly ash (*Max*) = 20 percent
GGBS (*Max*) = 25 percent

A-4.2.3 *Metakaolin*

Metakaolin conforming to the accepted standard [C-5(28)] may be used as pozzolanic material in concrete as part replacement of ordinary Portland cement only. The replacement level shall be maximum up to 15 percent.

A-4.2.4 *Ground Granulated Blast Furnace Slag* (*GGBS*)

GGBS conforming to the accepted standard [C-5(29)] may be used as part replacement of ordinary Portland cement. For concrete having embedded steel, the replacement level of GGBS shall be restricted to 50 percent by weight of cementitious materials. For resistance to sulphate and alkali aggregate reaction, GGBS up to 60 percent can be used.

A-4.2.5 *Ultrafine Ground Granulated Blast Furnace Slag* (*UFGBS*)

UFGBS conforming to the accepted standard [C-5(30)] may be used as part replacement of cement. The replacement level shall be up to 20 percent.

A-4.2.6 *Ultrafine Fly Ash*

Ultrafine fly ash produced through classification route and conforming to the accepted standard [C-5(31)] may be used as part replacement of ordinary Portland cement. The replacement level shall be up to 20 percent.

A-4.3 Chemical Admixtures

A-4.3.1 Chemical admixtures, as mentioned in Table 3 if used, shall comply with the accepted standard [C-5(32)]. Previous experience with and data on such materials should be considered in relation to the likely standards of supervision and workmanship to the work being specified.

Table 3 Types of Chemical Admixtures and their Constituents

(*Clause* A-4.3.1)

Sl No.	Type of Admixture		Typical Active Constituents
(1)	(2)		(3)
i)	Air-entraining	a)	Salts of wood resins
		b)	Some synthetic detergents
		c)	Salts of sulphonated lignin
		d)	Salts of petroleum acids
		e)	Salts of proteinaceous material
		f)	Fatty and resinous acids and their salts
		g)	Tall oils and gum rosin salts
		h)	Alkylbenzene sulfonates
		j)	Salts of sulphonated hydrocarbons
ii)	Retarding	a)	Unrefined lignosulphonate containing sugars
		b)	Modified derivatives of unrefined lignosulphonate
		c)	containing sugars
		d)	Hydroxycarboxylic acids and their salts
		e)	Carbohydrates including sugars
		f)	Heptonates related to sugars and starches
iii)	Accelerating	a)	Calcium chloride
		b)	Triethanolamine
		c)	Sodium thiocyanate
		d)	Sodium formate or calcium formate
		e)	Sodium nitrite or calcium nitrite
		f)	Calcium nitrate
		g)	Aluminates
		h)	Silicates
iv)	Water-reducing	a)	Lignosulfonic acids and their salts
		b)	Hydroxylated carboxylic acids and their salts
		c)	Polysaccharides
		d)	Melamine polycondensation products
		e)	Naphthalene polycondensation products
		f)	Polycarboxylates
v)	High range water-reducing : Normal and retarding	a)	Melamine sulfonate polycondensation products
		b)	Naphthalene sulfonate polycondensation products
		c)	Polycarboxylates
vi)	Shrinkage reducing	a)	Polyoxyalkylene alkyl ether
		b)	Propylene glycol

Table 3 (*Concluded*)

(*Clause* A-4.3.1)

Sl No. (1)	Type of Admixture (2)	Typical Active Constituents (3)
vii)	Corrosion inhibiting	a) Amine carboxylates aminoester organic emulsion
		b) Calcium nitrite
		c) Organic alkyidicarboxylic
		d) Chromates
		e) Phosphates
		f) Hypophosphites
		g) Alkalis
		h) Fluorides
viii)	Permeability-reducing admixture	
	1) *Non-hydrostatic conditions* (*PRAN*)	a) Long-chain fatty acid derivatives (stearic, oleic, caprylic capric)
		b) Soaps and oils (tallows, soya-based)
		c) Petroleum derivatives (mineral oil, paraffin)
		d) Fine particle fillers (silicates, talc)
	2) *Hydrostatic conditions* (*PRAH*)	Crystalline hydrophilic polymers (latex, water-soluble, or liquid polymer)

A-4.3.2 Chemical admixtures can be achieved by a spectrum of materials and manufacturing processes, but shall comply with accepted standard [C-5(28)]. Further, **c**hemical admixtures can be achieved by a spectrum of materials and manufacturing processes, but shall comply with the accepted standard [C-5(32)]. Further,

a) The workability, compressive strength and the slump loss of concrete with and without the use of admixtures shall be established during the trial mixes before use of admixtures;

b) The relative density of liquid admixtures shall be checked for each drum containing admixtures and compared with the specified value before acceptance;

c) If two or more admixtures are used simultaneously in the same concrete mix, data shall be obtained to assess their interaction and to ensure their compatibility;

d) Admixtures shall neither impair durability of concrete nor combine with the constituent to form harmful compounds nor increase the risk of corrosion of reinforcement; and

e) The chloride content of admixtures shall be independently tested for each batch before acceptance.

A-4.3.3 The amount of admixture added to a mix shall be recorded in the production record. Additional dose of admixture may be added at project site and mixed adequately in mixer itself to regain the workability of concrete (if necessary) with mutual agreement between the producer/supplier and the purchaser/user of concrete. But, the producer/supplier shall assure the ultimate quality of concrete supplied by him and maintain record of quantity and time of addition.

A-4.3.4 Shrinkage compensating admixtures shall not be used in structural concrete.

A-5 FIBRES

Fibres may be added to concrete for special applications to enhance select properties. But, such fibres shall be approved by the competent authority on the recommendation of a duly constituted competent peer review committee. In any case, the presence of fibres shall not be taken advantage of in the estimation of strength.

A-6 REINFORCEMENT

A-6.1 Reinforcing bars and prestressing strands shall be specified in accordance with the provisions of good practices [C-5(2) and (3)], respectively.

A-6.2 Reinforcement couplers shall comply with the relevant clauses of accepted standard [C-5(33)].

A-6.3 If glass fibre reinforced polymer bars are used, the material shall conform to the requirement of the accepted standard [C-5(34)].

A-6.4 Welded wire reinforcement shall conform to the requirements of the accepted standard [C-5(35)].

A-6.5 Prestressing accessories shall comply with the requirements of good practice [C-5(3)].

ANNEX B

(*Foreword*)

SELF COMPACTING CONCRETE

B-1 GENERAL

The self compacting concrete (SCC) is highly flowable, non-segregating concrete that fills uniformly and completely every corner of formwork by its own weight without the need for any compaction and encapsulates reinforcement or any other embedment. The provisions relating to its application areas, features, mix proportioning principles, and production and engineering properties are given hereunder. The provisions for concrete making materials and concrete as given in 'materials, workmanship, inspection and testing' section of the good practice [C-5(2)] shall apply to SCC except where different provisions or departures have been indicated hereunder.

B-2 APPLICATION AREAS

SCC may be used in in-situ concrete or for precast concrete applications. It is particularly appropriate for sections with highly congested reinforcement such as, nuclear power plant structures, machine foundations, piers and abutments; and areas having restricted access to concrete placement and compaction like shafts in hydropower structures. SCC is also suitable for the construction of tunnel lining sections and casting of concrete-filled steel tubular columns. SCC may also be used for columns and beams in normal construction with appropriate formwork design.

SCC may be produced in a batching plant on site or in ready-mixed concrete plant and transported to site by transit mixers. It may be placed either by pumping or other placement methods into horizontal or vertical forms.

B-3 FEATURES OF FRESH SELF COMPACTING CONCRETE

The features of fresh SCC are:

a) Filling ability (flowability);
b) Passing ability;
c) Segregation resistance; and
d) Viscosity.

B-3.1 Filling Ability (Flowability)

Filling ability of SCC determines its ability to flow into and fill all spaces within the formwork, under its own weight. The filling ability is tested using slump-flow test.

B-3.1.1 *Procedure*

Slump flow test shall be carried out in accordance with the accepted standard [C-5(36)].

B-3.1.2 *Classes of Slump-Flow and their Application*

There are three classes of slump-flow, as follows:

a) *SF*1 (slump flow 550 mm to 650 mm) – This class of SCC is appropriate for:

   1) unreinforced or slightly reinforced concrete structures that are cast from the top with free displacement from the delivery point (such as slabs); and

   2) casting by a pump injection system (such as tunnel linings), and 3) sections those are small enough to prevent long horizontal flow (example, piles and some deep foundations).

b) *SF*2 (slump flow 650 mm to 750 mm) is suitable for many normal applications (example, walls, columns); and

c) *SF*3 (slump flow 750 mm to 850 mm) is typically produced with a small maximum size of aggregates (less than 20 mm) and is used for vertical applications in structures having congested reinforcement, structures with complex shapes, etc. *SF*3 will often give better surface finish than *SF*2 for normal vertical applications but segregation resistance is more difficult to control.

B-3.2 Passing Ability (Free from Blocking at Reinforcement)

Passing ability describes the capacity of the fresh mix to flow through confined spaces and narrow openings such as areas of congested reinforcement without segregation. If there is little or no reinforcement, there may be no need to specify passing ability as a requirement. L-box test is generally carried out to check the passing ability and the procedure shall be in accordance with the accepted standard [C-5 (36)]. In this test, the height of the concrete left in the vertical section (h_1) and at the end of the horizontal section (h_2) is measured. The ratio of h_2/h_1 is calculated as the blocking ratio; which shall be between 0.8 and 1.0.

B-3.3 Segregation Resistance (Stability)

Segregation Resistance is the ability of fresh concrete to remain homogeneous in composition while in its fresh state. Segregation resistance is generally carried out using sieve test to check this property of fresh concrete.

B-3.3.1 *Procedure*

Segregation resistance (sieve) test shall be carried out in accordance with accepted standard [C-5(36)].

B-3.3.2 *Test Results*

There are two classes of segregation resistance, namely *SR*1 and *SR*2. For *SR*1 class, segregation resistance should be above 15 percent and $\leq$ 20 percent, and for *SR*2 it should be $\leq$ 15 percent.

*SR*1 is generally applicable for thin slabs and for vertical applications with a flow distance of less than 5 m and a confinement gap greater than 80 mm. *SR*2 is preferred in vertical applications if the flow distance is more than 5 m with a confinement gap greater than 80 mm in order to take care of segregation during flow. Segregation resistance becomes an important parameter with higher slump-flow classes and/or the lower viscosity class, or if placing conditions promote segregation. If none of these apply, it is usually not necessary to specify a segregation resistance class.

B-3.4 Viscosity

Viscosity can be assessed by the V-funnel flow time. Concrete with a low viscosity will have a very quick initial flow and then stop. Concrete with a high viscosity may continue to creep forward over an extended time.

B-3.4.1 *Procedure*

Viscosity by V-funnel test is carried out in accordance with accepted standard [C-5 (36)]. A V-shaped funnel is filled with fresh concrete and the time taken for the concrete to flow out of the funnel is measured and recorded as the V-funnel flow time.

B-3.4.2 *Test Results*

The viscosity is divided into two classes, namely V_1 and V_2. For V_1 class, the time taken to pass the concrete from V-funnel shall be $\leq$ 8 s and for V_2 class, it shall be above 8 s and $\leq$ 25 s.

V_1 has good filling ability even with congested reinforcement. It is capable of self levelling and generally has excellent surface finish. V_2 class viscosity is more likely to exhibit thixotropic effects, which may be helpful in limiting the formwork pressure or improving segregation resistance. But it may cause negative effects on surface finish and sensitivity to stoppages or delays between successive lifts.

B-4 MIX PROPORTIONING

B-4.1 Mix Proportion Principles

The principles listed below shall be followed:

a) Lower coarse aggregate content;

b) Increased paste content;

c) Low water/powder ratio (*see* Note);

d) High range superplasticizer; and

e) Viscosity modifying admixture, if required.

NOTE — Powder is the material of particle size smaller than 0.125 mm. It includes this size fraction in the cement, mineral admixtures and aggregate.

B-4.2 Mix Design Procedure

For mix design procedure, reference may be made to good practice [C-5(37)].

B-5 PRODUCTION OF SELF COMPACTING CONCRETE

B-5.1 General

SCC is less tolerant to changes in constituent characteristics and batching variances as compared to conventional concrete. Accordingly, it is important that all aspects of the production and placing processes are carefully supervised.

The production of SCC should be carried out in plants where the equipment, operation and materials are suitably controlled under a Quality Assurance Scheme. It is important that all personnel who will be involved in the production and delivery of SCC are adequately trained including practical demonstrations.

B-5.2 Constituents

SCC is more sensitive than conventional concrete to variation in the physical properties of its constituents and especially to changes in aggregate moisture content, grading and shape. So, more frequent production checks are necessary. The moisture content of aggregates should be continuously monitored and the mix adjusted to account for any variation.

Storage of constituent materials for SCC shall be same as that for materials for conventional concrete. However, as the SCC mix is more sensitive to variations, special precautions shall be taken for storage of aggregates, which should be properly stored to avoid cross-contamination between different types and sizes and protected from weather to minimize the fluctuation of surface moisture content and movement of fines. Ground stock should be stored in purpose-built partitioned bays, which should allow free drainage of excess moisture in the aggregates and rainwater.

B-5.3 Mixing Equipment and Trial Mixes

SCC shall be produced with efficient forced action concrete mixers. The time necessary to achieve complete mixing of SCC may be longer than for conventional concrete due to reduced frictional forces and to fully activate the superplasticizer.

B-5.4 Formwork

Formwork should be watertight and grout tight when placing SCC. The need to design the formwork for water tightness is greater than conventional formwork so as to avoid honeycombs and surface defects. The high fluid nature of SCC may lead to higher formwork pressure than conventional concrete, especially when the casting rate is high. As a result of the highly fluid nature of SCC, a high placement rate is likely and should be anticipated. Formwork designs, that accommodate the expected liquid head formwork pressure, can allow unrestricted placement rates and permit fast casting rate of the SCC. It is recommended to design the formwork for full liquid head.

B-5.5 Curing

Curing is essential for all concrete, and early protection of exposed surfaces is essential to preventing rapid moisture loss that could lead to plastic shrinkage cracking. The top-surface of elements made with SCC can dry quickly because of the increased quantity of paste, the low water/fines ratio and the lack of bleed water at the surface. Initial curing should therefore commence as soon as practicable after placing and finishing in order to minimize the risk of surface crusting and shrinkage cracks caused by early age moisture evaporation.

B-6 ENGINEERING PROPERTIES

B-6.1 General

SCC and conventional concrete of similar compressive strength have comparable properties.

B-6.2 Compressive Strength

SCC with a similar water-cement ratio usually have a slightly higher strength compared to conventional concrete due to the lack of vibration giving an improved interface between the aggregate and hardened paste.

B-6.3 Tensile Strength

SCC may be supplied with any specified concrete grade. For a given concrete grade, the tensile strength may be safely assumed to be the same as the one for a conventional concrete as the volume of paste (cement + fines + water) has no significant effect on tensile strength.

B-6.4 Static Modulus of Elasticity

Increasing the paste volume may decrease the modulus of elasticity, E_c. As SCC has higher paste content than conventional concrete, some difference can be expected and the E_c may be somewhat lower and should be adequately covered by the safe assumptions in design.

If SCC does have a slightly lower E_c than conventional concrete, in prestressing work, this will affect the relationship between the compressive strength and the camber due to pre-tensioning or post-tensioning. For this reason, careful control should be exercised over the strength at the time when the pre-tensioning and post-tensioning strands or wires are released.

B-6.5 Creep

Due to the higher volume of cement paste, the creep coefficient for SCC may be expected to be higher than for conventional concrete of equal strength, but such differences are small and shall be covered by the safe assumptions in design.

B-6.6 Shrinkage

As concrete compressive strength is related to the water-cement ratio, in SCC with a low water-cement ratio drying shrinkage reduces, but with increased cementitious content and increased water content the drying shrinkage and autogenous shrinkage can increase.

B-6.7 Durability

SCC is free from shortcomings due to improper compaction and result in consistently low and uniform permeability, offering less weak points for deleterious actions of the environment.

ANNEX C

(*Foreword*)

HIGH PERFORMANCE CONCRETE

C-1 GENERAL

High performance concrete is a concrete whose ingredients, proportions and production methods are specifically chosen to meet special performance and uniformity requirements. The higher performance requirements may be:

Sl No. (1)	*Higher Performance Requirements* (2)	*Remarks/Applications* (3)
i)	High resistance to deterioration of reinforced concrete due to carbonation	This is to help achieve longer service life. This is particularly applicable in semi-arid regions
ii)	High resistance to chloride attack/ingress	This is for longer service life of reinforced concrete exposed to severe chloride environment/coastal environment
iii)	High resistance to abrasion	This may be required in concrete structures, like parts of hydraulic structures exposed to continuous abrasive action due to silt, such as spillways/glacis; and concrete pavements exposed to heavy traffic
iv)	High resistance to impact	This may be required in structures like blast resistant structures and spillways
v)	Improvement in flexure and shear performance	This is required in bridge girders, joints of RCC framed structure, shear walls, etc
vi)	High resistance to cracking due to shrinkage (plastic and drying shrinkage)	This may be required in concrete/mortar used for repair of distressed concrete structures, etc

High strength concrete generally improves performance of all above parameters. The concrete mix proportioning for high strength concrete may be carried out in accordance with the good practice [C-5(37)]. However, special measures are needed to further improve the specific performance requirements. As a guide, the measures given in **C-2** may be adopted. For further details, expert literature may be referred.

C-2 MEASURES FOR IMPROVING SPECIFIC PERFORMANCE REQUIREMENTS

C-2.1 Resistance to Carbonation

Resistance to carbonation of concrete is dependent mainly upon:

a) Type of binder, content of binder and *p*H value of concrete; and

b) Permeability of concrete.

Addition of silica fume, GGBS and fly ash improve denseness and reduce permeability, thus increasing resistance to ingress of carbon dioxide and moisture (needed for carbonation). The addition of fly ash above 35 percent tends to lower the alkalinity, and thus the resistance to carbonation. Lower water-cement ratios and higher grades of concrete can be adopted to improve performance in this case. Minimum OPC content is essential for adequate carbonation resistance for different exposure conditions.

Carbonation resistance can be checked by using accelerated carbonation tests (using 3 percent to 4 percent CO_2 concentrations for minimum 70 days exposure) at mix proportioning stage. For quality assurance purpose, rapid tests like rapid chloride ion penetration test (RCPT), air permeability test or electrical resistivity test may be used. Their values may be established by correlation with accelerated carbonation test values at mix proportioning stage.

C-2.2 Resistance to Chloride Ingress

To improve performance of concrete exposed to chloride environment, two aspects need to be considered:

a) Total initial chloride content in concrete should be minimized; and

b) Permeability of concrete should be low.

Whereas chloride content of concrete can be controlled by checking chloride content of mix ingredients, the permeability of concrete can be reduced by careful selection of mix proportions and by use of supplementary cementing materials, either through use of blended cements like PPC and PSC or by direct addition of mineral admixtures, like fly ash, GGBS and silica fume. To control permeability, durability test of resistance to chloride ions shall be carried out by using chloride diffusion test by immersion or ponding method (using 3 percent NaCl exposure for 90 days) at mix proportioning stage. For quality assurance purpose rapid tests corresponding values like rapid chloride ion penetration test (RCPT) or electrical resistivity test shall be carried out. Corresponding values for these tests shall be established by developing a correlation with chloride diffusion test (by immersion/ponding) at mix proportioning stage.

C-2.3 Resistance to Abrasion

To ensure good performance against abrasion, following points should be considered:

a) Use of higher grades of concrete;

b) Use of good quality strong aggregate;

c) Use of silica fume; and

d) Use of steel fibres (suited for increasing abrasion resistance in spillways/glacis, etc).

Test methods for measuring abrasion resistance are:

a) Revolving disc type test; and

b) Under water abrasion resistance test using steel balls.

For further details regarding test methods and criteria, specialist literature may be referred.

C-2.4 Improving Performance in Flexure, Shear, Impact, Ductility and Energy Absorption

Resistance to impact is generally increased when the strength of concrete is high and energy absorption is high. Energy absorption and toughness can be increased by use of steel fibres in concrete. Whereas addition of steel fibres, glass or carbon fibres improves flexural and shear strength also, the use of synthetic fibres like polypropylene fibres do not significantly improve the above properties. Polypropylene fibres do however reduce shrinkage cracking and are suitable for concrete/mortar used for concrete repairs.

For checking impact resistance, falling weight impact test can be used, wherein number of blows for crack initiation in small concrete slab panel are counted.

For further details regarding test methods and criteria, specialist literature may be referred. The use of steel fibre reinforced concrete shall be further governed by **C-2.4.1**.

C-2.4.1 *Use of Steel Fibre Reinforced Concrete* (*SFRC*)

Following properties of concrete can be improved by using SFRC:

a) Ductility;

b) Toughness and energy absorption;

c) Abrasion; and

d) Flexural strength and shear strength.

Compressive and direct tensile strength gain in flexural and direct tensile strength is very significant when higher percentage of steel fibres are used which give the concrete a strain hardening effect (increase in ultimate load after initial crack). However significant improvements are achieved in strain softening zone also.

Steel fibres having aspect ratio 60 to 80 may be incorporated in concrete of different grades to improve the ductility of concrete. Fibre content varying from 0.5 percent to 2.5 percent volume may be incorporated in to the concrete to improve different mechanical and durability characteristics. However higher addition can cause problems in uniform mixing and placing of concrete which need to be checked at mix proportioning stage before using the mix. Corrosion of steel fibres can also occur particularly in lower grades, so use of coated fibres and higher grades of concrete are recommended. Alternatively, a plain concrete cover of few millimetre can also be provided.

Design of steel fibre reinforced concrete (SFRC) for structural performance shall be in accordance with Annex D.

ANNEX D

(*Foreword and Clause* C-2.4.1)

DESIGN OF STEEL FIBRE REINFORCED CONCRETE

D-1 GENERAL

This Annex shall apply where steel fibres are used to improve the performance and capacity of reinforced and prestressed concrete structures.

The design of steel fibre reinforced concrete (SFRC) at both the ultimate and serviceability limit states shall be based on the stress (σ) ≠ strain (ϵ) relationships for SFRC as specified in **D-3.3** (*see* Note 1).

Steel fibres shall not be relied upon in plastic hinge regions for strength requirements (*see* Note 2).

Steel fibres shall not be relied upon at constructions joints for either serviceability or strength requirements. Design procedure in this clause is for steel-fibre-reinforced concrete with a softening classification only (*see* Fig. 1). Hardening SFRC and the use of synthetic fibres is beyond the scope of this annex.

NOTES

1 When using brittle fibres that rely on a fibre pull-out failure mechanism to obtain member ductility, care is required for cases where a significant number of fibres fracture or where fibres result in local crushing of the concrete due to the local forces imposed on the matrix by the fibres. Fibre fracture may occur where the bond between the fibre and the matric is high, and this is more likely in a high strength concrete combined with fibres of high bond capacity and of lower strength steels.

2 The anchorage capacity of steel fibres may be lost in areas where crack widths exceed about 3.5 mm. Cracking of this magnitude can be expected in regions where plastic rotations are expected.

D-2 DEFINITIONS

For the purposes of this Annex the following definitions shall apply:

D-2.1 Crack Mouth Opening Displacement (CMOD) — The width of a crack shall be measured at its mouth in a flexural tensile test. To measure the CMOD, a displacement transducers/clip gauge shall be mounted along the longitudinal axis at the mid width of the test specimen (beam with nominal size of 150 mm × 150 mm and length L so that 550 mm < L < 700 mm).

D-2.2 Crack Opening Displacement (COD) — The width of a single localized crack, taken as an average on four sides, for a direct tensile test on a strain softening SFRC dog-bone shaped specimen in accordance with D-3.3.7.

D-2.3 Steel Fibre Reinforced Concrete (SFRC) — A mixture of concrete and steel fibres.

D-2.4 Hardening Behaviour — A material that displays an enhanced strength with increasing crack widths beyond that measured at the point of initial cracking of the cementitious matrix.

D-2.5 Softening Behaviour — A material that exhibits a loss of strength upon cracking.

D-2.6 Target Dosage — The specified quantity of fibres in kilograms per cubic metre of concrete (kg/m^3).

D-3 PROPERTIES OF SFRC

D-3.1 General

SFRC shall be classified in terms of both its characteristic compressive (cylinder) strength (f'_c) (*see* D-3.2) and its characteristic residual tensile strength ($f'_{1.5}$) (*see* D-3.3.3).

D-3.2 Compressive Strength

The characteristic compressive strength of SFRC at 28 days (f'_c) shall be determined in accordance with the accepted standard [C-5(38)].

In the absence of more accurate data, the mean value of the in situ compressive strength (f_{cmi}) shall be taken as 90 percent of the mean value of the cylinder strength ($f$cm).

NOTE — The compressive strength of steel fibre reinforced concrete (SFRC) should be determined by means of standard tests on concrete cylinders. The addition of steel fibres to concrete in conventional dosages (less than 100 kg/m^3) does not change the compressive properties of the concrete.

D-3.3 Tensile Properties

D-3.3.1 *Classification*

SFRC shall be classified as either softening or hardening as shown in Fig. 1. Hardening SFRC is outside the scope of this Annex.

NOTES

1 A hardening material is defined as one with a tensile strength equal to or greater than 1.1 times the strength of the matrix without fibres and taken at a crack opening displacement (COD) of equal to or greater than 0.3 mm.

2 A hardening material is one where multiple cracks can occur prior to crack localization. For material hardening to occur, the fibre dosage is typically such that the strength of the SFRC is at least 10 percent greater than the strength of the same concrete mix without fibres. The value of COD of 0.3 is sufficiently high such that matrix contribution to the strength of the composite is minimal and the tension at this point is substantially taken by the fibres alone.

D-3.3.2 *Matrix Tensile Strength*

The matrix tensile strength of the softening SFRC (f_{ct}) shall be obtained using flexural tensile testing, in accordance with good practice [C-5(2)].

When only the characteristic compressive (cylinder) strength (f'_c) has been determined, the mean and characteristic flexural tensile strength of SFRC shall be calculated in accordance with the good practice [C-5(2)].

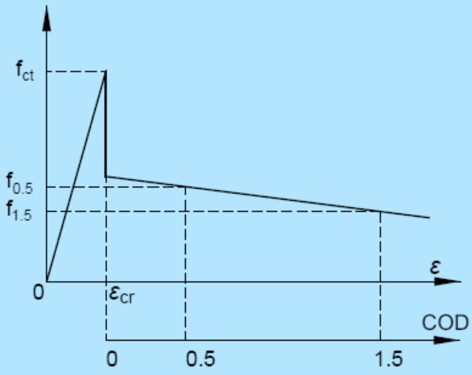
NOTE — For strain softening SFRC, the peak strength of the composite may be approximated as the strength of the concrete mix without fibres.

D-3.3.3 *Residual Tensile Strength*

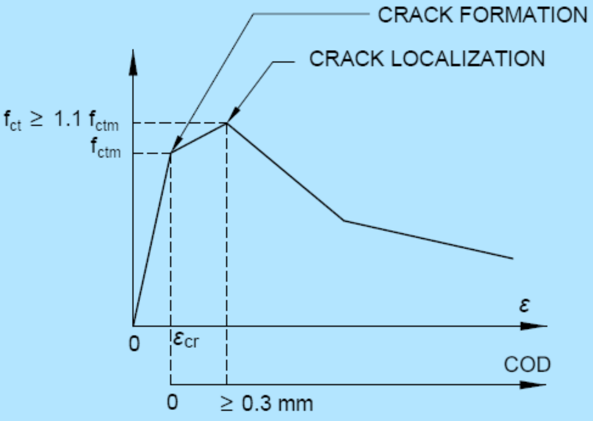
The standard characteristic residual tensile strength grades ($f'_{1.5}$) are 0.4 MPa, 0.6 MPa, 0.8 MPa, 1.2 MPa, 1.6 MPa and 2.0 MPa.

The characteristic residual tensile strengths of concrete at 28 days ($f'_{1.5}$) shall be determined statistically from tests carried out in accordance **D-3.3.4** or **D-3.3.5**.

NOTE — The characteristic residual tensile strength depends on the fibre-matrix bond strength, which is usually a function of the compressive strength of the parent concrete, as well as the fibre content. It may be unrealistic to specify a high value of $f'1.5$ when using a relatively low value of $f'c$.



1A STRAIN SOFTENING SFRC



1B STRAIN HARDENING SFRC

FIG. 1 CLASSIFICATION OF SFRC

D-3.3.4 *Determination of Strength by Direct Testing*

The characteristic residual tensile strength ($f'_{1.5}$) shall be obtained using direct tensile tests as specified in **D-3.3.7**.

Alternatively, where matched direct and indirect testing has been undertaken in accordance with **D-3.3.6** for similar SFRC mixtures, the characteristic residual tensile may be determined as:

$$f'_{1.5} = k_{R,4}\, f'_{R,4}$$

Where $f'_{R,4}$ is determined in accordance with **D-3.3.8** and calculated statistically, and the factor $k_{R,4}$ determined from **D-3.3.6**.

For the purposes of this clause, similar SFRC mixtures are defined as having the same:

a) Fibre type and content;

b) Water to cementitious material ratio;

c) Maximum aggregate particle size; and

d) Compressive strength (f'_c).

NOTES

1 In calculating the characteristic strength, the population may be treated normally distributed and the strength determined in accordance with accepted standard. A confidence level of 75 percent shall be used that 95 percent of the population exceeds the characteristic value.

2 The sample standard deviation shall not exceed 25 percent.

D-3.3.5 *Determination of Strength by Indirect Testing*

The characteristic residual tensile strength ($f'_{1.5}$) may be obtained using indirect tests as specified in **D-3.3.8** and calculated as:

$$f'1.5 = 0.4f'_{R,4} - 0.07f'_{R,2}$$

D-3.3.6 *Residual Tensile Strength-Residual Flexural Strength Relationship*

The relationship between residual tensile strength and the residual flexural strength shall be obtained by matched using the same SFRC mixture. Residual tensile strength specimens shall be prepared and tested in accordance with **D-3.3.7**. Residual flexural tensile tests shall be in accordance with the procedure as mentioned below:

The average width of the specimen and distance between the tip of the notch and the top of the specimen in the mid-span section shall be determined from two measurements to nearest 0.1 mm width and distance in the notch port of the specimen using calipers.

When the CMOD is measured, the displacement transducer shall be mounted along the longitudinal axis at mid width of test specimen such that the distance 'y' between the bottom of specimen and line of measurement is 5 mm or less as mentioned in Fig. 2.

a) The concrete mix shall be batched to ensure a uniform distribution of fibres, the SFRC shall be placed in the moulds in a manner that does not interfere with the distribution of the fibres and, the SFRC shall be compacted using lightly applied external vibration; and

b) A minimum of 12 specimens shall be tested.

The reference factor $k_{R,4}$ shall be determined as:

$$k_{R,4} = f_{1.5m}/f_{R,4m}$$

where

$f_{1.5m}$ = mean residual tensile strengths corresponding to a COD of 1.5 mm, determined in accordance with **D-3.3.7**.

$f_{R,4m}$ = mean residual flexural tensile strengths corresponding to a CMOD of 3.5 mm, determined in accordance with **D-3.3.8**.

NOTE — The residual tensile strength (as obtained from a direct tensile test) is a fundamental material property of SFRC. This clause allows the concrete producer and steel fibre manufacturer to correlate the direct tensile strength of their particular SFRC mix design with the flexural tensile strength.

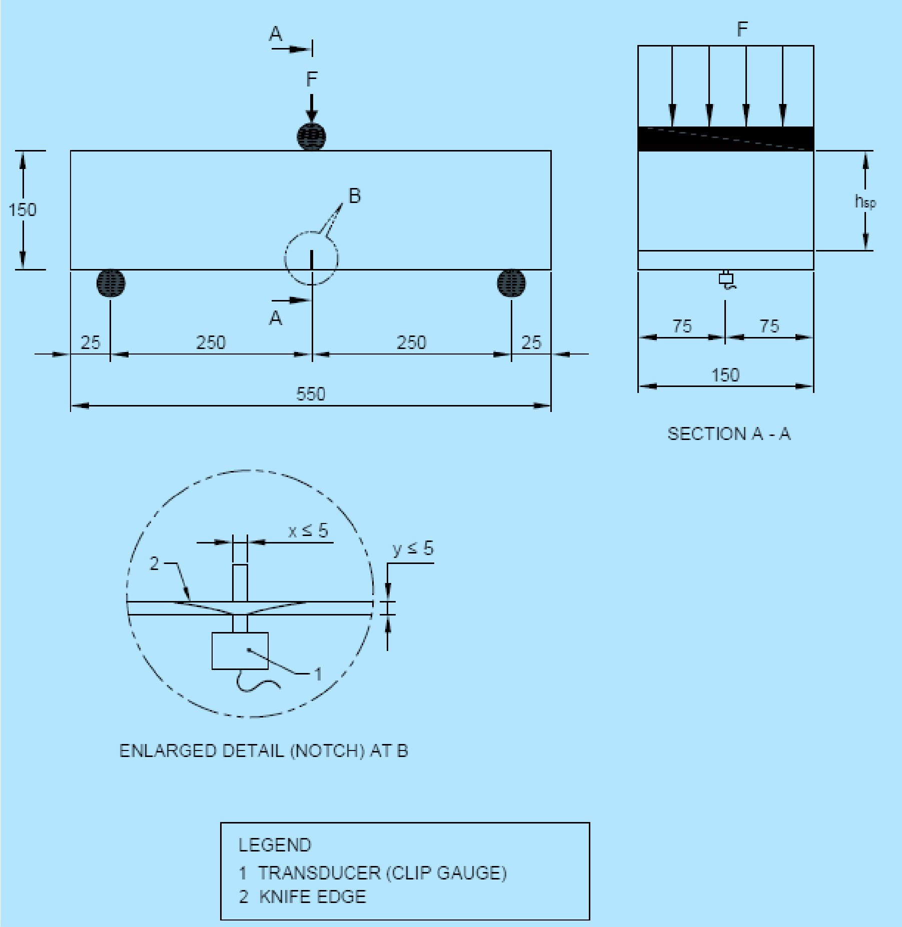


FIG. 2 ARRANGEMENT FOR RESIDUAL FLEXURAL TENSILE TEST

D-3.3.7 *Residual Tensile Strength Test*

The residual tensile strength shall be obtained using the testing arrangement shown in Fig. 3 and with the following criteria:

a) The critical section shall be where the cross sectional area is a minimum;

b) The SFRC mix shall be batched to ensure a uniform distribution of fibres, and shall be placed in the moulds in a manner that does not interfere with the distribution of the fibres. The SFRC shall be compacted using lightly applied external vibration;

c) The specimen shall be connected to the testing machine in such a manner that the machine does not apply a load to the specimen during the process of tightening of the grips and prior to testing;

d) One end of the specimen shall be connected to the testing machine through a universal joint such that no moment is applied to the end of the specimen;

e) Displacement measurements shall be taken on each of the four sides with the COD taken as the average of these measurements;

f) A minimum of twelve specimens shall be tested;

g) Tests where the failure of the specimen is outside of the testing region, or where the results are influenced by the test specimen boundaries, shall be retested;

h) The characteristic values of the tensile strength $f_{0.5}$ and $f_{1.5}$, corresponding to CODs of 0.5 mm and 1.5 mm, respectively, shall be determined statistically as the 95 percentile confidence value assuming the population is normally distributed; and

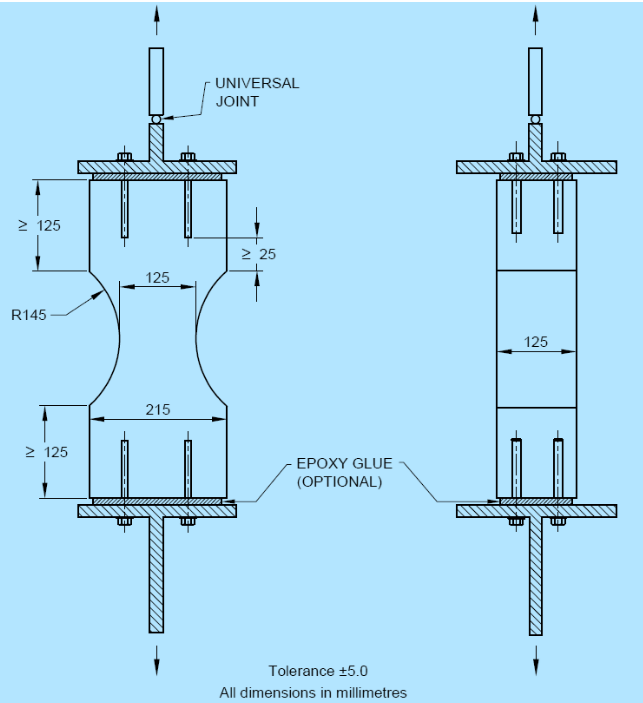
j) The mean values of $f_{0.5m}$ and $f_{1.5m}$, corresponding to CODs of 0.5 mm and 1.5 mm, respectively, shall be determined statistically as the 50th percentile confidence value assuming the population is normally distributed.

The stress results obtained from the test shall be multiplied by the three-dimensional orientation factor k_1, where,

$$k_1 = \frac{1}{0.94 \ + 0.6\ell_f/b} \leq 1$$

And ℓ_f is the length and b is taken as the average of the width and depth of the specimen taken at the critical section.

NOTE — The factor k_1 removes the influence of the boundaries on the fibre distribution and converts the results of the test to a state where the fibres can be considered to be randomly orientated in three-dimensional space.



Tolerance ±5.0
All dimensions in millimetres

FIG. 3 TESTING ARRANGEMENT FOR DIRECT TENSION

NOTE — There is considerable discussion in the literature on whether the ends of the specimens should be fixed at each end, pinned at each end or fixed at one end and pinned at the other. The adoption of one pinned and one fixed end is a pragmatic decision between the ideal condition (fixed at each end) and limitations in manufacturing of specimens that are perfectly square at their ends for alignment within the testing machine. With both ends fixed any misalignment induces a moment in the specimen during gripping. This moment can induce a tensile stress on one side of the specimen, weakening the specimen. In some situations, the moment induced may be sufficient to crack the concrete. The inclusion of the universal joint at one end eliminates residual tensions that may result from the gripping procedure.

D-3.3.8 *Residual Flexural Tensile Strength*

The residual flexural tensile strength (F_R) shall be determined from 3 point notched bending tests on 150 mm square section prisms. The notch depth shall be 25 mm and the test conducted in accordance with **D-3.3.6**. The force F shall be plotted against the crack mouth opening displacement (CMOD), as shown in Fig. 4 and the residual flexural stress calculated as:

$$F_R = \frac{3F_{RJ}L}{2bh_{sp}^2}$$

where

F_{RJ} = load recorded at CMOD$_j$ (*see* Fig. 4).

L = span, in mm;

b = width, in mm of the specimen; and

h_{sp} = distance, in mm between tip of the notch and top of cross section.

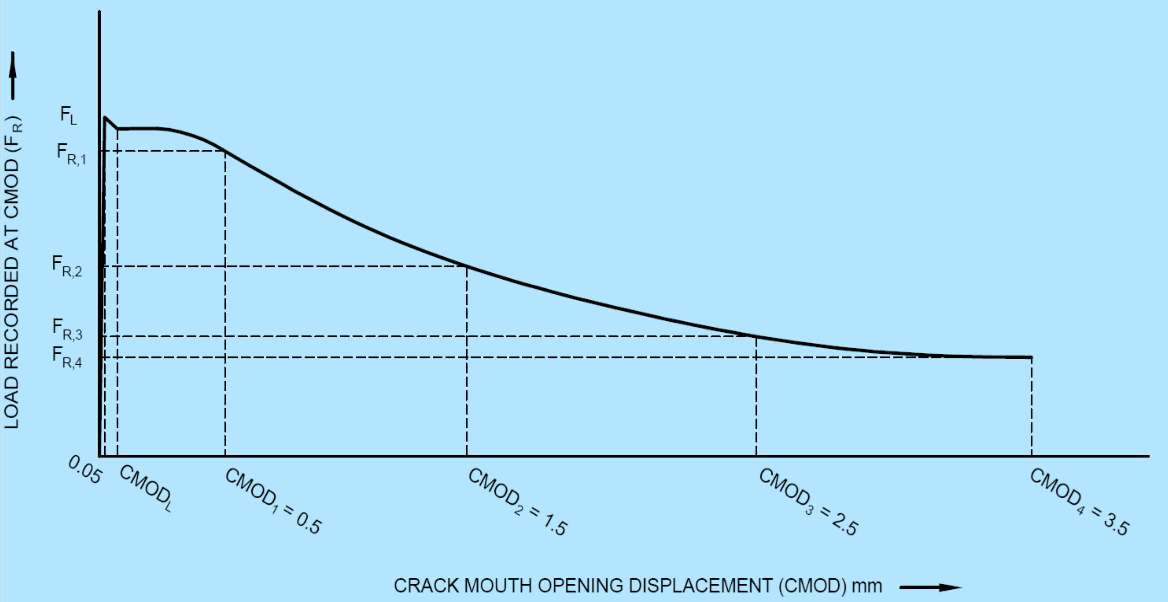


FIG. 4 LOAD *VERSUS* CMOD FOR RESIDUAL FLEXURAL TENSION

D-3.4 Modulus of Elasticity

The mean modulus of elasticity at the appropriate age (E_{cj}) shall be determined in accordance with accepted standard [C-5(38)].

NOTE — The addition of steel fibres to concrete in conventional dosages (100 kg/m^3 and less) does not change the elastic modulus of the concrete.

D-4 DESIGN OF REINFORCED SFRC MEMBERS

D-4.1 General

This clause applied to reinforced and prestressed beams subjected to any combination of shear force, bending moment and axial force. This clause does not apply when torsion acts in conjunction with shear or to non-flexural members.

D-4.2 Strength of Beams in Bending and Combined Bending and Axial Force

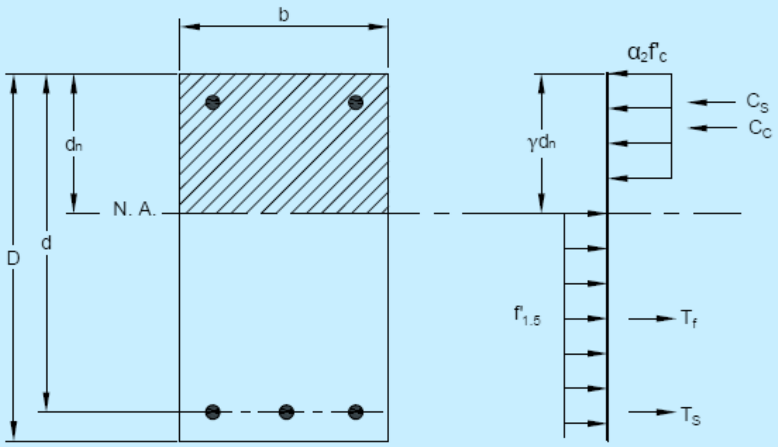
Calculations for strength of cross sections in bending shall incorporate equilibrium and strain-compatibility considerations and be consistent with the following assumptions:

a) Plane sections normal to the axis shall remain plane after bending;

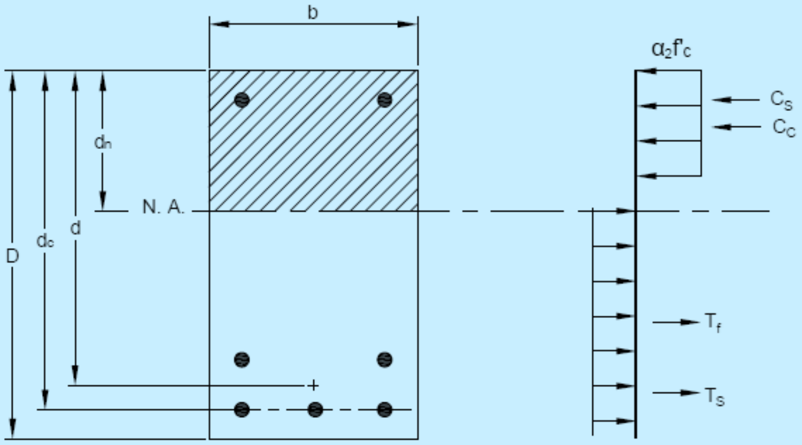
b) Stress in the fibre reinforced concrete in that part of the cross section in tension shall be taken to be $f'_{1.5}$, where $f'_{1.5}$ is the characteristic residual tensile stress determined in accordance with **D-3.3.3**; and

c) Distribution of compressive stress shall be determined from a stress-strain relationship for the concrete.

The strength of a section in bending, or in combined bending and axial force, shall be determined using rectangular stress blocks for the concrete in compression and concrete in tension, as shown in Fig. 5.



5A SINGLE TENSILE REINFORCEMENT LAYER



5B MULTIPLE TENSILE REINFORCEMENT LAYERS

FIG. 5 STRESS BLOCKS AND FORCES ON REINFORCED SFRC SECTION

D-4.3 Minimum Reinforcement Requirements for Bending

The minimum tensile reinforcement shall be not less than that determined using the principles given in this annex, excluding fibres.

D-4.4 Strength of Beams in Shear

D-4.4.1 *Design Shear Strength of a Beam*

The design shear strength of a beam shall be taken as V_u

where

$$V_u = V_{uc} + V_{uf} + V_{us}$$

where V_{uc} and V_{us} are determined from **39** of accepted standard [C-5(38)] and V_{uf} is determined from D-4.4.2.

Notwithstanding the above equations, the fibres component to the shear strength of a beam, V_{uf}, shall not exceed the greater of 0.3 V_u and that determined by D-4.4.3 with V_{us} taken as zero.

D-4.4.2 *Contribution to Shear Strength by Steel Fibres*

The contribution of the fibres to the ultimate shear strength (V_{uf}) of an SFRC beam shall be calculated from the following equation:

$$V_{uf} = 0.7 k_\theta b_v d_0 f'_{1.5}$$

where

k_θ = $\cot \theta_v \leq 1.28$

b_v = The effective width of the web (the vertical part of the beam).

d_0 = The effective depth of the beam.

$f'_{1.5}$ = characteristic residual tensile strength of concrete (at 28 days) at a Crack Opening Displacement (COD) of 0.5 mm.

θ_v = the angle between the axis of the concrete compression strut and the longitudinal axis of the member and shall be taken as not less than 38°.

D-4.4.3 *Minimum Shear Reinforcement*

The minimum contribution from the total of the transverse steel reinforcement and fibres shall satisfy the following:

$$(V_{us} + V_{uf})_{min} \geq 0.1 b_v d_0 \sqrt{f'_c} \quad and \quad \geq 0.6 b_v d_0$$

D-4.5 Design for Serviceability Limit States

D-4.5.1 *General*

When an SRFC cross sectional is uncracked, the full cross section shall be assumed to be active and both concrete and steel are assumed to be elastic in tension as well as in compression.

When an SRFC cross section is cracked, the SFRC shall be assumed to be elastic in compression, and capable of sustaining a tensile stress equal to 1.1 $f'_{1.5}$.

NOTE — Prior to cracking, linear elastic behaviour is assumed for the SFRC, reinforcement and the bonded tendons in both tension and compression. After cracking, the SFRC in tension is assumed to carry a tensile stress of 1.1 $f'_{1.5}$, while the SFRC in compression, the reinforcement and the bonded tendons are assumed to be linear elastic.

D-4.5.2 *Stress Limits*

D-4.5.2.1 *Concrete*

The maximum compressive stress in the concrete at the serviceability limit states shall not exceed $0.6 f_{cm}(t)$. Under permanent effect loading, the maximum compressive stress in the concrete shall not exceed $0.4 f_{cm}(t)$.

NOTES

1 The satisfaction of limits on the concrete tensile stress at the serviceability limit state is not necessary if the member performance is satisfactory at the ultimate limit state.

2 Compressive stresses are limited to avoid large time-dependent deformations and to ensure creep behaviour remains linear with respect to stress. Restrictions on the tensile stress in SFRC are not necessary provided the member satisfies all other requirements at the strength and serviceability limit states.

D-4.5.2.2 *Reinforcing steel*

To avoid any inelastic deformation that could lead to large, permanently open cracks, tensile stresses in the reinforcement at the serviceability limit states shall not exceed $0.8 f_{sy}$.

D-4.5.3 *Minimum Reinforcement for Crack Control*

The minimum amount of longitudinal reinforcement required to obtain controlled crack formation shall be:

$$A_{\mathrm{st,min}} = k_1 k_\mathrm{c} k_\mathrm{p} f_{\mathrm{ct,ef}} - 1.1 f'_{1.5} \frac{A_{\mathrm{ct}}}{f_{\mathrm{s,max}}} \geq 0.0 \text{ (mm}^2\text{)}$$

where

$A_{\mathrm{st,min}}$ = minimum area of reinforcement required within the tensile zone (mm^2). If $A_{st,\mathrm{min}}$ is zero only steel fibres are necessary to control cracking;

k_1 = coefficient which allows for the effect of non-uniform self-equilibrating stresses due to non-linear shrinkage or temperature profiles through the member depth. In the absence of more detailed analysis, k_1 may be taken as 0.8;

k_c = coefficient that takes account of the nature of the stress distribution within the section immediately prior to cracking. The relevant stress distribution is that resulting from the combined effects of loading and restrained imposed deformations:

= 1.0 for pure tension ($e = M/N = 0$)

= 0.6 for pure bending

k_p = a coefficient that takes account of the level of prestress and is given by:

$$k_p = 1 - \frac{\sigma_{\mathrm{cp}}}{k k_c f_{ct,ef}}\left(1 - k_c + 2.4\frac{e}{D} - 6k_c\frac{e}{D}\right)$$

$f_{\mathrm{ct,ef}}$ = tensile strength of the concrete effective at the time when the cracks may first be expected to occur (MPa). Values of $f_{\mathrm{ct,ef}}$ shall be obtained from $0.6\sqrt{f_{\mathrm{cm}}}$ but not less than 3.0 MPa and f_{cm} is the mean concrete compressive strength at the time cracking is expected to occur;

A_{ct} = area of concrete within the tensile zone (mm^2). The tensile zone is that part of the cross section calculated to be in tension just before formation of the first crack;

$f_{\mathrm{s,max}}$ = maximum stress permitted in the reinforcement immediately after formation of the crack;

e/D = ratio of the eccentricity of the prestressing force on the cross section, e, measured from the centroidal axis of the uncracked section to the overall depth of the cross section, D; and

σ_{cp} = average intensity of the effective prestress ($P_\mathrm{e}/A_\mathrm{g}$).

D-4.5.4 *Deflection Control*

D-4.5.4.1 *General*

The deflection of an SFRC member shall be calculated using the procedures outlined in **D-4.5.4.2** and **D-4.5.4.3**. Allowance shall be made for the expected load history, the expected construction procedure and any anticipated deflections resulting from deformation of forms or settlement of props.

D-4.5.4.2 *Short-term deflection*

The short-term deflections due to external loads and prestressing, which occur immediately on their application, shall be calculated using the value of E_{cj} determined in accordance with this Annex and the value of the effective second moment of area of the member (I_{ef}). The value of I_{ef} may be determined from the values of I_{ef} at nominated cross sections as follows:

a) For a simply supported span, the value at mid-span;

b) In a continuous beam:

   1) For an interior span, half the mid-span value plus one quarter of each support value; or

   2) For an end span, half the mid-span value plus half the value at the continuous support.

c) For a cantilever, the value at the support.

For the purpose of the above determinations, the value of I_{ef} at each of the cross sections nominated in items (a) to (c) is obtained from the instantaneous curvature $k_\mathrm{i} = M_s^*/(E_{\mathrm{cj}}\, I_{\mathrm{ef}})$ calculated as the slope of the strain diagram in

Fig. 6B and obtained by satisfying the requirements for rotational and horizontal equilibrium of the stress distribution in Fig. 6C.

NOTE — The procedure for calculating short-term deflection is consistent with the approach in this Annex. Short-term deflection of a cracked section is calculated based on the assumed stress and strain distribution shown in Fig. 6. The assumption of a uniform tensile stress in the cracked region of the SFRC is considered to be reasonable for the determination of the neutral axis location and curvature and, hence, for the determination of the effective second moment of area (I_{ef}).

6A SELECTION 6B STRAIN 6C STRESS 6D FORCES

Fig. 6 Stress and Strain Distribution on a Cracked Section Subjected to Applied In-Service Bending Moment (M_s*)

D-4.5.4.3 *Long-term deflection*

For reinforced and prestressed SFRC flexural members, that part of the deflection that occurs after the short term deflection shall be calculated as the sum of:

a) The shrinkage component of the long-term deflection, determined from the design shrinkage strain of concrete (ε_{cs}) and the principles of mechanics; and

b) The additional long-term creep deflections, determined from the design creep coefficient of concrete (φ_{cc}) and the principles of mechanics.

In the absence of more accurate calculations, the additional long-term deflection of a reinforced SFRC beam due to creep and shrinkage may be calculated by multiplying the short-term deflection caused by the sustained loads by a multiplier, k_{cs}, as follows:

$$k_{cs} = \left[2 - 1.2\left(\frac{A_{sc}}{A_{st}}\right)\right] \geq 0.8$$

NOTES

1 For the calculation of long-term deflection, two alternative approaches are specified. For reinforced and prestressed beams, the shrinkage and creep components of the long-term deflection may be calculated separately using the material data specified in the Annex and the principles of mechanics. The shrinkage component of the long-term deflection may be readily determined from the shrinkage-induced curvatures calculated at the critical sections along the span of the beam using the design shrinkage strain, (εcs). The creep component of long-term deflection may be obtained from the creep-induced curvatures at the critical sections under the sustained service loads using the creep coefficient for concrete, (φcc).

2 Alternatively, for reinforced concrete beams and slabs, the additional long-term deflection caused by creep and shrinkage may be approximated by multiplying the short-term or immediate deflection caused by the sustained load by the deflection multiplier kcs. The deflection multiplier depends on the ratio Asc/Ast, where Asc is the area of the longitudinal reinforcement in the compressive zone of the cracked section (that is, between the neutral axis and the extreme compressive fibre of the cracked cross section) and *A*st is the area of the tensile reinforcement.

D-5 DURABILITY

The minimum concrete grade and cover for SFRC in respective exposure classification shall be as for concrete without fibres and shall apply to the steel reinforcement only. SFRC shall not be used in exposure classification C1 or C2.

NOTES

1 Steel fibres do not require concrete cover as specified for steel reinforcement.

2 SFRC may not be suitable in some exposure classification U environments.

3 Fibres close to the surface are subject to corrosion and may result in surface staining. This will not impact durability.

D-6 FIRE

The structural performance of SFRC for fire shall be determined in accordance with this annex. The material properties for SFRC shall be as specified for concrete in this Annex except that to characteristic residual tensile stress of SFRC at elevated temperatures ($f'_{1.5 2\theta}$) shall be either:

a) Taken as ($f'_{1.5 2\theta}$) = $k_{\theta 1} \times f'_{1.5}$ where $k_{\theta 1}$ is given in Table 4; or

b) Determined statistically from tests.

Table 4 Elevated Temperature Coefficient for Residual Tensile Stress of SFRC

(*Clause* D-6)

Sl No. (1)	Temperature of SFRC °C (2)	$k_{\theta 1}$ (3)
i)	0	1.0
ii)	100	1.0
iii)	500	0.6
iv)	700	0.1
v)	1200	0.0

NOTE — Linear interpolation between the values is permitted.

D-7 PRODUCTION OF SFRC

D-7.1 Fibres

Steel fibres shall comply with accepted standard. The 'Certificate of Conformity' shall be supplied on request to the relevant authority.

NOTE — Till the availability of a separate Indian Standard specification for steel fibres, reference may be made to ASTM A820 : 2022 'Standard Specification for steel fibers for fiber-reinforced concrete'.

D-7.2 Mixing of Fibres

Fibres of the type and quantity specified shall be added in a controlled process ensuring that they are dispersed uniformly through the concrete mix. If added after the main mixing process, the concrete shall be remixed until the fibres have been completely dispersed throughout the batch.

NOTES

1 Balling of fibres should be avoided.

2 A record of fibre content should be recorded for each batch.

D-7.3 Pre-Construction Testing of Materials

Pre-construction testing in the form of initial type tests shall be undertaken in accordance with Table 5. New initial type tests shall be undertaken when any of the following occur:

a) The concrete composition changes;

b) At least one source material of the concrete changes;

c) The results of compressive tests undertaken as per this Annex do not meet the specification; and

d) At least once in a period of 12 months.

The pre-construction tests shall be performed with the same personnel, materials and equipment that will be used during production.

Table 5 Pre-Construction Tests

(*Clause* D-7.3)

Sl No. (1)	**Material** (2)	**Inspection/Test** (3)	**Purpose** (4)
i)	Steel fibres	a) Check delivery note	Verify that the delivery is in accordance with the order, and is shipped from the correct source
		b) Check conformity label	Verify that the fibres have the correct conformity label which matches the corresponding certificate of conformity
ii)	Steel fibre content in the fresh concrete	Testing according to **D-7.5** on the basis of 9 samples	Conformity with the target dosage. Verify homogeneous distribution of the steel fibres in the mix
iii)	Steel fibre concrete performance	Check limit of proportionality, and post-crack flexural strength in accordance with **D-3.3.6** on a minimum of 12 beams	Verify, if the performance is in accordance to the specification. The performance level serves as the reference for continuous production control

NOTE — The strength of the population may be treated as normally distributed and the characteristic strength determined in accordance with this annex. A confidence level of 75 percent shall be used such that 95 percent of the population exceeds the characteristic value. For a sample of 12 specimens, the characteristic strength may be calculated from the mean strength using characteristic strength = mean strength × (1 – 1.84 × COV). The coefficient of variation (COV as a percentage) shall not exceed 25 percent.

D-7.4 Factory Production Control

Factory production control is accordance with Table 6 shall be undertaken to establish a production process for the steel fibre reinforced concrete, and shall include the following:

a) Checking the correct concrete constituents are being used in production;

b) Steel fibres are checked against specified requirements;

c) Compressive tests undertaken in accordance with good practice [C-5 (40)]; and

d) Fibre content and distribution.

Table 6 Routine Production Control

(*Clause* D-7.4)

Sl No.	Subject	Inspection/Test	Purpose	Frequency
(1)	(2)	(3)	(4)	(5)
i)	*Equipment inspection*			
	a) Automatic dosing equipment for steel fibres	1) Visual inspection	Assure correct functioning of dosing device	Once per production day
		2) Control of accuracy	Avoid improper fibre dosage	On installation periodically in case of doubt
ii)	*Materials inspection*			
	a) Steel fibres	1) Check delivery note	Verify that the delivery is in accordance with the order, and is shipped from the correct source	Each delivery
		2) Check conformity requirements	Verify that the fibres matches the corresponding Certificate of Conformity	Each delivery
		3) Visual control, measure fibre dimensions	Compare the fibre geometry with the fibres used for ITT	Each delivery
iii)	*Production process inspection*			
	a) Fibres content-record	1) Record the quantity added	Check the content	Every batch
	b) Fibre content in the fresh concrete	2) Testing according to **D-7.5**	Conformity with the target dosage Verify homogenous distribution of the steel fibres in the mix	Beginning of each day and every/ 50 m^3 (manual dosing) and/150 m^3 (auto dosing)
	c) Concrete mix	3) Visual Check	Correct mixing with correct fibre type and even fibre distribution without balling	Daily
iv)	*Finished product inspection*			
	a) Steel fibre concrete performance	1) Check limit of proportionality, and post-crack flexural strength in accordance with **D-3.3.6**	Check performance level of the specification	2 beams every other day of production

D-7.5 Determining the Steel Fibre Content

Steel fibre content shall be measured from samples taken from the production concrete, by volume of concrete.

In addition:

a) A sample shall be taken from the batch of concrete at unloading from the first third, middle third and final third of the batch;

b) Each sample shall be a minimum of 10 litre;

c) The sample container shall be filled in one continuous pour and where possible directly from the discharge chute; and

d) Wash out or magnetic separation only shall be used.

The conformity of the correct steel fibre dosage is proven if the criteria in Table 7 are met.

Table 7 Criteria of Acceptance for Steel Fibre Dosage

(*Clause* D-7.5)

Sl No. (1)	Test Control (2)	Test Control (3)	Criteria (4)
i)	Each sample	Each partial test	≥ 0.80 of the specified target dosage
ii)	Average of 3 samples from the batch	Each test	≥ 0.85 of the specified target dosage
iii)	Continuous control: average of > 3 tests	Continuous control average of > 3 tests	≥ 0.90 of the specified target dosage

D-7.6 Sampling, Testing and Assessment for Compliance of Hardened SFRC

When concrete is specified by parameters other than strength grade, the method of production control and, if required, project control shall be specified together with the relevant compliance criteria.

Methods of control and assessment shall provide a reliable operating characteristic curve so that:

a) Concrete with a proportion defective of 0.05 has a probability of acceptance of at least 50 percent; and

b) Concrete with a proportion defective of 0.30 has a probability of rejection of at least 98 percent.

ANNEX E

(*Foreword and Clause* 5)

CRITERIA FOR STRUCTURAL SAFETY OF TALL CONCRETE BUILDINGS

E-1 SCOPE

E-1.1 This Annex covers the following design aspects of reinforced concrete (RC) buildings of height greater than 50 m, but less than or equal to 250 m. Generally, these requirements are based on prescriptive approach and covers the following design aspects of tall buildings:

a) Selection of appropriate structural system;

b) Geometric proportioning of the building;

c) Integrity of structural system;

d) Resistance to wind and earthquake effects; and

e) Other special considerations related to tall buildings.

E-1.2 This Annex is not applicable for tall buildings located in the near-field of seismogenic faults. For the purposes of this standard, near-field is taken as 10 km (shortest distance) from a seismogenic fault.

E-1.3 This Annex is applicable only for buildings that house 20 000 or fewer persons.

E-1.4 This Annex may also be used for design of buildings of height equal to or less than 50 m. The provisions of this Annex will add value to the design of such buildings. However, this Annex is not applicable for design of buildings of height more than 250 m.

E-1.5 This Annex addresses the following typical structural systems of tall concrete buildings:

a) Structural wall systems;

b) Moment frame systems;

c) Moment frame — Structural wall systems;

d) Structural wall — Flat slab floor systems with perimeter moment frame;

e) Structural wall — Framed tube systems;

f) Framed-tube system;

g) Tube-in-tube system;

h) Multiple tube system;

j) Hybrid system; and

k) Any of the above with additional framing systems, for example, outrigger trusses, belt trusses and braced frames.

E-1.6 This Annex shall be read along with all Indian Standards relevant to design and construction of buildings and structures. In case of conflict, clauses given in this Annex shall be applicable.

E-1.7 For buildings that do not conform to the prescriptive requirements of this Annex, a more rigorous procedure is necessary for design and review.

E-2 -

NOTE — (This clause is intentionally left blank.)

E-3 TERMINOLOGY

For the purpose of this Annex, the following definitions shall apply.

E-3.1 Building Height — The difference in levels between the base level of a building, at which inertia forces generated in the structure are transferred to the foundation, which then transfers these forces to the ground, and the highest level of a building, which is the roof of the topmost level which is structurally integral and continuous with the floor below (*see also* E-4).

E-3.2 Connecting Structure — A structure that links two or more towers, except at the podium levels.

NOTE — There are two distinctive types of connecting structures with each one requiring a different structural treatment, namely, (a) the connecting structure having the role of transferring gravity loads only and with no participation in the role of resisting the lateral loads on either of the towers; and (b) the connecting structure participating in the lateral load resisting structural system, where the two towers act together when one or both towers is subjected to lateral loads due to the interaction provided by the connecting tower.

E-3.3 Core — An assembly of structural walls coupled with link elements and offering lateral stiffness in two orthogonal directions.

E-3.4 Coupled Structural Wall Building — A building comprising of structural walls linked by in-plane beam elements, wherein the vertical and lateral loads are resisted by these structural walls, through axial load, in-plane bending moment and shear force, and the coupling action created by push-pull in the wall elements by framing action provided by link beams.

E-3.5 Frame Building — A building comprising beams and columns, wherein the vertical and lateral loads are resisted by these elements through moment-frame action.

E-3.6 Gravity Columns — Vertical members that are intended to carry primarily the vertical loads arising out of the dead and imposed loads on the building, and do not participate in the lateral load resisting system. Such columns shall be capable primarily of carrying the gravity loads and additional induced loads while complying with the relative lateral deformation effects imposed on them during lateral earthquake shaking.

E-3.7 Key Elements — The element such that its failure would cause the collapse of more than a limited area close to it. The limited area may be taken equal to 70 m^2 or 15 percent of the area of the storey, whichever is lesser. If key elements exist, it is preferable to modify the layout so that the key element is avoided.

E-3.8 Linking Beams (Also called coupling beams) — Horizontal members spanning two (vertical) structural walls.

E-3.9 Mixed Building or Hybrid Building — A building in which select primary elements resisting vertical and/or lateral loads comprise more than one material; composite elements comprising structural steel and reinforced concrete are common examples.

E-3.10 Multi-Tower Structures Linked by Podium — Two or more towers above a common podium structure that are not separated by a movement joint at the podium level.

E-3.11 Natural Period — The time taken (in seconds) by the structure to complete one cycle of oscillation in its natural mode of oscillation.

E-3.12 Structural Systems and Sub-Systems

E-3.12.1 *Structural Wall System* — A structural system comprising of inter-connected structural walls, wherein the vertical and lateral loads are resisted by the walls through axial load, in-plane bending moment and shear force. The wall elements are configured by a combination of structural wall elements connected integrally to a floor diaphragm. The wall elements form the primary lateral load resisting structural system for the building, and resist the loads imposed on them through axial, shear and flexural actions, and through coupling actions offered by the connecting link elements if provided.

E-3.12.2 *Moment Frame System* — A structural system comprising (beam-column) frames and resisting the vertical and lateral loads.

E-3.12.3 *Moment Frame-Structural Wall System* — A structural system comprising (beam-column) frames and structural walls resisting the vertical and lateral loads. The relative share of the lateral load resisted between these systems is dependent on their relative lateral stiffnesses.

E-3.12.4 *Structural Wall System with Flat Slab Floor System* — A structural system comprising structural walls, a beam-less floor system, and columns resisting the vertical and lateral loads. The relative share of the lateral load resisted between these systems is dependent on their relative lateral stiffnesses.

E-3.12.5 *Core and Outrigger Structural System* — A structural system comprising wall element(s) and perimeter columns, resisting the vertical and lateral loads. Essentially, the perimeter columns are for resisting gravity loads only. The core structure is connected to select perimeter column element(s) (often termed outrigger columns) by beam elements, known as outriggers, at discrete floor locations along the height of the building. This type of structure is an extension of the core structure, to enhance the lateral stiffness for taller structures, which mobilizes the perimeter columns, and offers increased leverage for push pull-action through the framing action offered by the deep beam(s) connecting the core to the outrigger columns. The global lateral stiffness is sensitive to: flexural stiffness of the core element, the flexural stiffness of the outrigger element(s) and the axial stiffness of the outrigger column(s).

E-3.12.6 *Core, Outrigger and Belt Wall System* — A structural system, which is an extension to the core and outrigger structure to enhance the lateral stiffness further, where the outrigger column(s) is linked to the adjacent columns by deep beam elements (often known as belt truss), typically at the same level as the outrigger elements. The sharing of loads between multiple columns has the dual function of enhancing the axial stiffness and mobilizing greater number of gravity columns to counteract the induced tension loads generated by the overall lateral loads.

E-3.12.7 *Framed-Tube System* — A structural system comprising closely spaced columns and deep beams in the perimeter frame for efficient tube action. The internal vertical elements, comprising core or columns are primarily utilized to resist gravity loads only. Effective utilization of the perimeter of the building maximizes the overall stiffness for a given building plan shape; this system is effective for very tall buildings.

E-3.12.8 *Tube-in-Tube System* — A structural system, which is an extension of the tube structure, where there is an internal tube, often a core element, supplementing the external perimeter described as the tube structure above, to enhance the overall lateral global stiffness. Just as the tube structure, typically, even this system is suited for very tall buildings.

E-3.12.9 *Multiple-Tube System* — A structural system, which is an extension of the tube structure and/or the tube-in-tube structure, where the architectural plan of the tower facilitates multiple tubes to be connected together, to enhance the lateral stiffness of the structure. Just as the tube structure and the tube-in-tube structure, typically, this suited is reserved for very tall buildings.

E-3.13 Super Tall Building — A building of height greater than 250 m.

E-3.14 Tall Building — A building of height greater than 50 m, but less than or equal to 250 m.

E-3.15 Transfer Structure — A structure, comprising of horizontal deep beams, trusses or thick slabs that transfers load actions and supports vertical elements above to vertical elements below that are not aligned with each other, through flexural and shear actions. Alternatively, it can be a trussed structure that fulfils the task through axial actions in the truss members.

E-4 SYMBOLS

For the purpose of this Annex, the following letter symbols shall have the meaning indicated against each; where other symbols are used, they are explained at appropriate places. All dimensions are in metres (m), loads in Newton (N), stresses in mega Pascals (MPa) and time in seconds (s), unless otherwise specified.

a — Major axis of elliptic plan shape of the building

A_{cr} — Cracked area of section

A_{g} — Gross area of section

b — Minor axis of elliptic plan shape of the building

h_{i} — Inter-storey height of i^{th} floor in the building

l_{s} — Clear span of coupling beam

B — Smaller plan dimension of the building at its base

B_{t} — Width of tower above podium level

D — Dimension of the building in plan along the considered direction of earthquake shaking

d — Overall depth of coupling beam

H — Building height from its base to roof level:

a) excluding the height of basement storeys, if basement walls are connected with the ground floor slab or basement walls are fitted between the building columns, but;

b) including the height of basement storeys, if basement walls are not connected with the ground floor slab and basement walls are not fitted between the building columns

H_{t} — Height of tower above podium level

h_w — Unsupported height of structural wall

I_{eff} — Effective or cracked moment of inertia of section

I_{g} — Gross moment of inertia of section

L — Larger plan dimension of the building at its base

L_{t} — Length of the tower above podium level

M_u — Factored bending moment at a cross-section in a vertical member of the building

P_u — Factored axial load at a cross-section in the vertical member of the building

P_{uz} — Factored pure axial load capacity (at $M_u = 0$) of a vertical member of the building

T_a — Approximate fundamental translational lateral natural period

Δ_{max} — Maximum relative lateral displacement within the storey

E-5 GENERAL REQUIREMENTS

E-5.1 Elevation

E-5.1.1 *Height Limit for Structural Systems*

The maximum building height (in m) shall not exceed values given in Table 8 for buildings with different structural systems.

Table 8 Maximum values of Height *H* above Top of Base Level of Buildings with Different Structural Systems, in Metre

(*Clause* E-5.1.1)

Sl No.	Seismic Zones	Structural System				
		Moment Frame	Structural Wall Well Distributed$^{1)}$	Structural Wall + Moment Frame	Structural Wall + Perimeter Frame	Structural Wall + Framed Tube*
(1)	(2)	(3)	(4)	(5)	(6)	(7)
i)	V	NA	120	150	150	180
ii)	IV	NA	150	200	200	225
Iii)	III	60	200	225	225	250
iv)	II	80	250	250	250	250

$^{1)}$ Structural walls are considered to be well-distributed when structural walls that are outside of the core are capable of carrying at least 25 percent of the lateral loads.

* This includes systems covered under **E-1.5 (g)**, **E-1.5 (h)** and **E-1.5 (k)**.

E-5.1.2 *Slenderness Ratio*

The maximum values of the ratio of height to minimum base width *B* shall not exceed values given in Table 9.

Table 9 Maximum Slenderness Ratio (H_t/B_t)

(*Clause* E-5.1.2)

Sl No.	Seismic Zones	Structural System				
		Moment Frame	Structural Wall Well Distributed	Structural Wall + Moment Frame	Structural Wall + Perimeter Frame	Structural Wall + Framed Tube*
(1)	(2)	(3)	(4)	(5)	(6)	(7)
i)	V	NA	8	8	9	9

Table 9 (*Concluded*)

(*Clause* E-5.1.2)

Sl No.	**Seismic Zones**	**Structural System**				
		Moment Frame	Structural Wall Well Distributed	Structural Wall + Moment Frame	Structural Wall + Perimeter Frame	Structural Wall + Framed Tube*
(1)	(2)	(3)	(4)	(5)	(6)	(7)
ii)	IV	NA	8	8	9	9
iii)	III	4	8	8	9	10
iv)	II	5	9	9	10	10

* This includes systems covered under **E-1.5(g)**, **E-1.5(h)** and **E-1.5(k)**.

E-5.1.3 *Aerodynamic Effects*

Elevation profile, façade features of the building, and plan shape of the building shall be such as to attract minimum wind drag effects. Effects of features such as sharp corners, projected balconies, etc, shall be considered in design.

E-5.2 Plan

E-5.2.1 *Plan Geometry*

E-5.2.1.1 The plan shall preferably be rectangular (including square) or elliptical (including circular). In buildings with said plan geometries, structural members participate efficiently in resisting lateral loads without causing additional effects arising out of re-entrant corners and others.

E-5.2.2 *Plan Aspect Ratio*

The maximum plan aspect ratio (L_t/B_t) of the overall building shall not exceed 5.0. In case of an L-shaped building, L_t and B_t shall refer to the respective length and width of each leg of the building.

E-5.3 Storey Stiffness and Strength

Parameters influencing stiffness and strength of the building should be so proportioned, that the following are maintained:

a) Lateral stiffness of any storey shall not be less than 70 percent of that of the storey above; and

b) Lateral strength of any storey shall not be less than 90 percent that of the storey above.

E-5.4 Deformations

E-5.4.1 *Lateral Drift*

When design lateral forces are applied on the building, the maximum inter-storey lateral drift ratio (Δmax/h_i) under serviceability loads (including wind load with return period of 20 years), which is estimated based on the sectional properties for serviceability loads mentioned in **E-7.2**, shall be limited to 1/500. Total drift at the topmost usable floor shall be limited to H/500. For a single storey the drift limit may be relaxed to h_i/400.

E-5.5 Natural Modes of Vibration

E-5.5.1 The natural period of fundamental torsional mode of vibration shall not exceed 0.9 times the smaller of the natural periods of the fundamental translational modes of vibration in each of the orthogonal directions in plan.

E-5.5.2 The fundamental translational lateral natural period in any of the two horizontal plan directions, shall not exceed 8 s, considering sectional properties as per **E-7.2(c)** corresponding to serviceability loads.

E-5.6 Floor Systems

E-5.6.1 *Material*

All floor slabs shall be cast in-situ. For precast floor systems a minimum structural topping of 75 mm concrete with reinforcing mesh shall be used in Seismic Zones III and above, but can be reduced to 50 mm in Seismic Zone II.

E-5.6.2 *Openings*

E-5.6.2.1 Openings in floor diaphragm shall not be permitted along any floor diaphragm edge, unless perimeter members are shown to have stability and adequate strength.

E-5.6.2.2 The maximum area of openings in any floor diaphragm shall not exceed 30 percent of the plan area of diaphragm. Transfer of lateral forces from diaphragm to lateral load resisting vertical elements shall be ensured using collector elements, if required.

E-5.6.2.3 At any storey, the minimum width of floor slab along any section after deduction of openings shall not be less than 5 m, if there is no perimeter beam. Further, the cumulative width of the slab at any location shall preferably not be less than 50 percent of the floor width.

E-5.6.3 *Natural Frequency of Floor System*

The natural vertical vibration frequency of any floor system shall not be less than 3 Hz without demonstration of acceptability using rational procedures.

E-5.7 Materials

E-5.7.1 *Concrete*

E-5.7.1.1 The minimum grade of concrete shall be M 30.

E-5.7.1.2 The maximum grade of concrete shall be M 70. When higher grades are required, the designer shall ensure through experimentation that such concretes shall have at least a minimum crushing strain in compression of 0.002.

E-5.7.2 *Reinforcing Steel*

E-5.7.2.1 Reinforcing seel shall conform to provisions of good practice [C-5(5)].

E-5.7.2.3 Lapping of longitudinal bars shall be avoided in RC columns and walls that form a part of the lateral load resisting system; when diameter of bars is 20 mm or higher; mechanical couplers as per accepted standard [C-5(33)] shall be used to extend bars.

E-5.8 Progressive Collapse

Following are general guidelines to avoid progressive collapse of structure.

E-5.8.1 Possibilities of progressive collapse shall be precluded by:

a) Selecting structural systems that are appropriate for ensuring structural integrity;

b) Adopting rigorous structural investigations that verify acceptable structural behaviour, even when select critical members do not play their intended role; and

c) Providing adequate redundancy and integrity to the structure.

E-5.8.2 *Requirements of Key Elements*

E-5.8.2.1 Key elements are members, joints or other components, whose failure would result in a disproportionate deterioration of the building and whose presence is vital to ensure ductile behaviour of the building. Vertical and lateral resistance of key elements shall be improved in many ways, including by the use of higher partial safety factors for loads and materials, to ensure that they do not yield before the designated ductile elements.

E-5.8.2.2 Elements adjoining key elements and capable of providing an alternative load transfer path, shall be suitably designed and detailed.

E-6 LOADS AND LOAD COMBINATIONS

E-6.1 The loads and load combinations specified in Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS, the good practice [C-5(2)] and good practice [C-5(5)]shall be applicable for tall buildings also. In addition, requirements given in subsequent clauses shall be applicable.

E-6.2 Wind Effects

E-6.2.1 For buildings (a) with height greater than 150 m, or (b) with complexities in plan or elevation geometry, or (c) sited on complex topography with group effect or interference effect (existing and future potential),or (d) whose natural period is greater than 5 s, wind effects shall be determined by site-specific wind tunnel studies.

E-6.2.2 *Site-Specific Wind Tunnel Studies*

E-6.2.2.1 When wind tunnels studies result in higher storey shears and overturning moments than those calculated at based on **4** of Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS, the results of wind tunnel studies may be used in design.

E-6.2.2.2 When wind tunnel studies result in lower story shears and moments than those calculated based on **4** of Part C/Section 1 of this NBCS,

a) The minimum design wind base shear shall be at least 70 percent of that derived based on **4** of Part C/ Section 1 of this NBCS; and

b) The relative distribution of storey shears shall be as obtained from wind tunnel studies.

E-6.2.2.3 When wind tunnel studies indicate torsional motion, structural system of the building should be modified suitably to mitigate the torsional effects, so as to bring the torsional velocity below 0.003 rad/s for 10 year return period.

E-6.2.2.4 The damping ratio considered shall not be greater than 2 percent of critical for concrete buildings.

E-6.2.3 *Lateral Acceleration*

From serviceability considerations, under standard wind loads with return period of 10 years, the maximum structural peak combined horizontal acceleration a_{max} in the building for along and across wind actions at any floor level shall not exceed values given in Table 10, without or with the use of wind dampers in the building.

Table 10 Permissible Peak Combined Acceleration

(*Clause* E-6.2.3)

Sl No. (1)	**Building Use** (2)	**Maximum Peak Combined Acceleration, a_{max}** m/s^2 (3)
i)	Residential	0.18
ii)	Mercantile	0.25

E-6.3 Seismic Effects

E-6.3.1 Vertical shaking shall be considered simultaneously with horizontal shaking for tall buildings in Seismic Zone V.

E-6.3.2 For buildings in Seismic Zone V, deterministic site-specific design spectra may preferably be estimated and used in design. When site-specific investigations result in higher hazard estimation, site-specific investigation results shall be used.

E-6.3.3 Design base shear coefficient of a building under design lateral forces, shall not be taken less than that given in Table 11.

Table 11 Minimum Design Base Shear Coefficient (Percent of Seismic Weight)

(*Clause* E-6.3.3)

Sl No.	Building Height, *H*	Seismic Zone			
		II	III	IV	V
(1)	(2)	(3)	(4)	(5)	(6)
i)	$H \leq 120$ m	0.7	1.1	1.6	2.4
ii)	$H \geq 200$ m	0.5	0.75	1.25	1.75

NOTE — For buildings of intermediate height in the range 120 m to 200 m, linear interpolation shall be used.

E-6.3.4 *Approximate Fundamental Natural Period*

For buildings of height 50 m and more, the fundamental period T (in s) for a structure shall be determined by accounting for all structural properties and inherent stiffness of the building through rigorously validated structural analysis procedures. The fundamental period shall however not exceed the value obtained from the approximate fundamental translational natural period T_a (in s) of oscillation, estimated by following expression:

$$T_a = 0.0644 H^{0.9} \text{ for concrete moment resisting frame systems}$$

and

$$T_a = 0.0672 H^{0.75} \text{ for all other concrete structural systems}$$

E-7 STRUCTURAL ANALYSIS

E-7.1 Software

Structural analysis shall be carried out using standard 3-D computer model using well-established structural analysis software.

E-7.2 Considerations

Computer modelling shall consider the following:

a) Rigid end offsets of linear members in the joint region, when centerline modelling is adopted;

b) Floor diaphragm flexibility, as applicable;

c) Cracked cross sectional area properties as per Table 12; and

d) The load combination for the initial analysis considering *P-Δ* effects shall be taken as: 1.2 DL + 0.5 IL ± 1.5 EL/WL.

E-7.3 Modelling

E-7.3.1 Modelling of buildings shall follow a simple approach, which reflects the distribution of mass and stiffness properties to properly account for all significant inertial forces under seismic actions and deformation shapes.

E-7.3.2 Analytical model of a building shall reflect the true behaviour of its members as well of the whole structure. One can adopt lumped modelling that is frame element modelling, distributed modelling that is finite element modelling or a combination of the two.

Table 12 Cracked Section Properties of RC Members

(*Clauses* E-7.2 *and* E-7.3.6)

Sl No.	Structural Element	Serviceability Design		Strength Design	
		Cross-Sectional Area	Moment of Inertia	Cross-Sectional Area	Moment of Inertia
(1)	(2)	(3)	(4)	(5)	(6)
i)	Slabs	$1.0\ A_g$	$0.35 I_g$	$1.00\ A_g$	$0.25\ I_g$
ii)	Beams	$1.0\ A_g$	$0.7\ I_g$	$1.00\ A_g$	$0.35\ I_g$
iii)	Columns	$1.0\ A_g$	$0.9\ I_g$	$1.00\ A_g$	$0.70\ I_g$
iv)	Walls	$1.0\ A_g$	$0.9\ I_g$	$1.00\ A_g$	$0.70\ I_g$

E-7.3.3 In-plane stiffness of floor slabs shall be modelled, unless it is demonstrated that it is extremely stiff and sufficiently strong to remain elastic under seismic actions. *See* **5** of Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS to identify when a floor slab may be considered to be extremely stiff in its own plane.

E-7.3.4 In moment frame buildings, when buildings with unreinforced masonry infill panels contribute to storey lateral stiffness, their effect shall be modelled as equivalent diagonal struts as per relevant provisions of **5** of Part C/Section 1 of this NBCS.

E-7.3.5 The analytical model for performing dynamic analysis of buildings with irregular configuration shall adequately represent irregularities in the configuration of the building.

E-7.3.6 Cracked sectional properties shall be used when representing concrete elements as per Table 12.

E-7.3.7 In reinforced concrete buildings, lateral deflections resulting from unfactored lateral loads shall be estimated using section properties intended for use with unfactored lateral loads, and lateral deflections resulting from factored lateral loads using section properties intended for use with factored lateral loads.

E-7.3.8 Buildings may be considered to be fixed at their bases for determining lateral effects on buildings. When modelling flexibility of foundations, reference shall be made to **E-8** and **E-9**.

When foundation flexibility is included in linear analysis, load-deformation characteristics of foundation-soil system shall be accounted for by equivalent linear stiffness, using soil properties that are consistent with soil strain levels associated with the design forces. A 50 percent increase and decrease in stiffness shall be incorporated in dynamic analysis, unless smaller variation can be justified; the largest value of response shall be used in the raft design.

E-7.3.9 Second order deformation effects (P-Δ effects) shall be considered.

E-7.3.10 The flexibility of the building shall be such that the inter-storey drift stability coefficient θ satisfies

$$\theta = \frac{P_i \Delta_i}{V_i h_{i-1} R} \le 0.2$$

where

P_i = total design vertical load at level i;

Δ_i = design storey drift at level i;

V_i = design shear force at level i;

h_{i-1} = storey height below level i; and

R = response reduction factor.

E-7.3.11 Stiffness of frames with flat slabs as horizontal members (that is, slab-column frames) shall be ignored in lateral load resistance, in all Seismic Zones. These shall be designed as gravity elements for deformation compatibility.

E-7.3.12 The model used in structural analysis of solid, coupled, perforated or punched structural walls shall represent stiffness, strength and deformation capacities of structural wall, structural wall segments and coupling beams or spandrel connections between structural walls. Stiffness of coupling beams and spandrel connections shall capture aspect ratio of these coupling beam and spandrel connections, extent of cracking anticipated, and reinforcement provided in them.

E-7.3.13 Effects shall be considered of construction sequence in buildings taller than 150 m.

E-7.3.14 Tower(s) connected by a podium shall be modelled separately and integrally.

E-7.4 Building Movements

For buildings taller than 150 m, and for buildings taller than 100 m with mass asymmetry, analysis shall be carried out for both vertical and horizontal long-term building movements.

E-7.4.1 Measures shall be taken in concrete and composite buildings to minimize adverse effects of shrinkage, creep, temperature variation and foundation settlement during the design life of the building (not less than 30 years).

E-7.4.2 Non-structural elements, such as curtain walls, cladding, partitions and finishes and service installations (for example, elevators, vertical pipes, ducts and cables), shall be required to withstand long-term movements of the building and associated differential effects.

E-7.4.3 Details of connections of non-structural elements with the structural elements of the building shall be planned, such that their relative movements are allowed without causing distress to both structural and non-structural elements.

E-7.4.4 Appropriate vertical compensation and sway compensation shall be accounted for during construction to minimize long term building movements for concrete and composite structures.

E-7.4.5 In gravity load analysis, internal forces shall be considered, which are developed due to differential vertical movement of vertical structural elements, due to shrinkage, creep, temperature, foundation settlement and construction compensation. In any case the total shrinkage strain of concrete shall not exceed 0.04 percent.

E-7.4.6 To calculate the effect of creep and shrinkage, selected strain prediction models of concrete shall be based on established principles of mechanics elaborated in specialist literature.

E-8 STRUCTURAL DESIGN

E-8.1 General Requirements

E-8.1.1 *Method of Design*

Limit state design method (as given in [C-5(2)]) shall be used in the design of RC members.

E-8.1.2 *Staircase*

Staircases built integrally with the structural system of the building and not confined by structural walls, shall be included in the three-dimensional structural model, and its elements designed as per forces induced in them under various load combinations. Alternately a sliding joint may be provided.

E-8.1.3 *Multiple Tall Buildings connected with a Common Podium*

E-8.1.3.1 This section deals with requirements for the following tall buildings with podium:

a) Tall building with single tower and podium (*see* Fig. 7A); and

b) Tall building with multiple towers and common podium (*see* Fig. 7B).

E-8.1.3.2 *Modelling*

E-8.1.3.2.1 *Sensitivity analyses*

a) As part of collapse prevention evaluation, two sets of backstay sensitivity analyses shall be carried out using upper-bound and lower-bound cracked section properties of floor diaphragms and the stiffness parameters for those diaphragms and perimeter walls of podium and below the level of the backstay are given in Table 13. These analyses shall be in addition to those required to be carried out using other cracked section properties described in **E-7.2(c)**.

Table 13 Stiffness Parameters

[*Clauses* E-8.1.3.2.1(a) *and* E-8.1.3.3.3(d)(2)]

Sl No.	**Stiffness Parameter**	**Values to be Adopted**	
		Upper-Bound	Lower-Bound
(1)	(2)	(3)	(4)
i)	$I_{\text{eff}} / I_{\text{g}}$	0.5	0.15
ii)	$A_{\text{cr}} / A_{\text{g}}$	0.5	0.15

b) Besides that of the floor diaphragms, flexibility of following structural elements in the structural analysis with appropriate modification to their stiffness:

1) Perimeter walls and their foundation supports; and

2) Foundation supports under the tower lateral load resisting system.

E-8.1.3.3 *Buildings with multiple towers*

E-8.1.3.3.1 *Backstay*

Backstay transfers the forces from lateral load-resisting elements in the tower to additional structural elements provided within the podium and the basement, typically through one or more floor diaphragms. Lateral load resistance in the podium levels with assured force transfer path through floor diaphragms at these levels, helps the tall building to resist lateral overturning forces. This component of overturning resistance, referred as the backstay effect (also called shear reversal), is critical because shear force changes direction within the podium levels, and the same lateral load-resisting element helps resist the changing shear force.

The following shall be considered:

a) In estimating backstay effects, two lateral load paths shall be considered (*see* Fig. 8), namely:

1) *Direct load path* — where overturning resistance is provided by the tower core elements and foundation directly beneath the tower; and

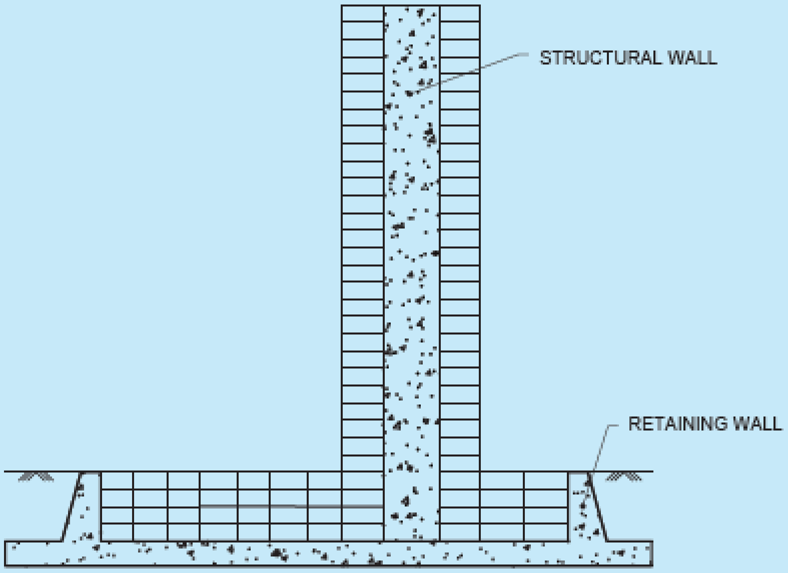
2) *Backstay load path* — where overturning resistance provided by in-plane forces in the backstay elements (lower floor diaphragm and perimeter walls).

In some tall buildings, backstay effects may not be considered. These include the following configurations:

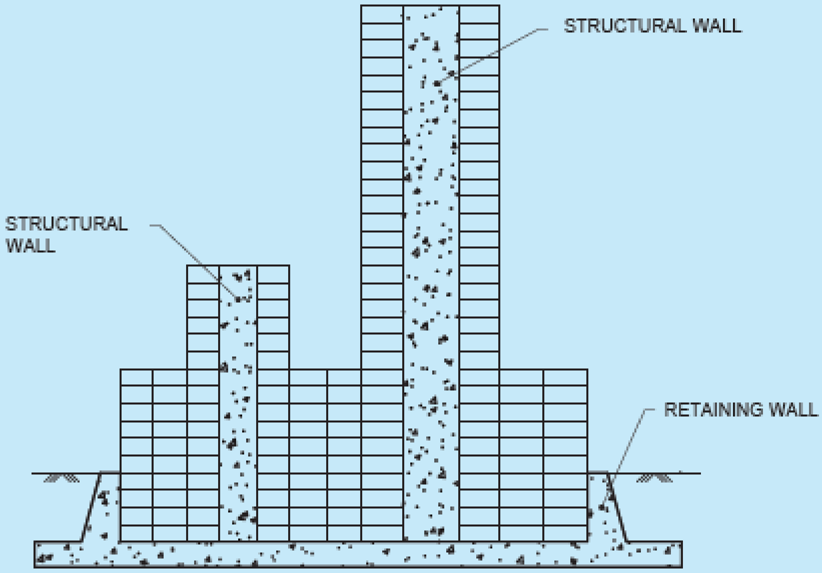
i) Buildings without below grade levels or buildings without significantly increased lateral load resisting systems at the base;

ii) Buildings that extend below grade, but have structural separations between the superstructure and the podium portions of the building, and that accommodate lateral load deformations without transfer of lateral forces from superstructure portion to podium portion; and

iii) Buildings with perimeter basement walls, where the walls are located directly below the lateral load resisting elements of the superstructure above. Here, there may be a marked change in lateral strength and stiffness at this level, but lateral forces will not be transferred through the floor diaphragms.



7A SINGLE TOWER



7B MULTIPLE TOWERS

FIG.7 TALL BUILDINGS WITH PODIUMS, CORE STRUCTURAL WALL AND BELOW-GRADE PERIMETER RETAINING WALL

b) Backstay floor diaphragms shall be modelled considering their in-plane and out-of-plane floor flexibility. Any large discontinuity present in the slab shall be modelled;

c) In direct load path case, vertical stiffness shall be considered of the piles, foundation and supporting soil;

d) In backstay load path case, relative stiffness shall be considered of floor diaphragms and perimeter walls, along with vertical in-plane rocking stiffness of soil below the walls. Also, horizontal pressure imposed by soil on retaining walls shall be considered. Axial stiffness of elements (representing backstay) along load path shall be reduced to account for cracking, bond slip, interface slip and other such effects;

e) In tall buildings with backstay diaphragms, collector elements shall be provided (*see* Fig. 8), which are capable of transferring forces from the lateral load-resisting system of the tower to the additional elements providing the resistance and in turn to those forces of the podium. Such collector elements shall be provided for transferring lateral forces originating in the other portions of the structure;

f) The backstay diaphragms shall be designed in accordance with the following:

  1) They shall be designed for the maximum of forces derived from sensitivity analysis;

  2) When the lateral force resisting system of a tall building has plan irregularity as per **5** of Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS of Type I (torsion irregularity), Type II (re-entrant corners) and Type IV (out of plane offsets), and vertical irregularity as per **5** of Part C/Section 1 of this NBCS of Type IV (in-plane discontinuity of vertical elements resisting lateral forces), seismic forces shall be amplified by a factor of 1.5 in the design of:

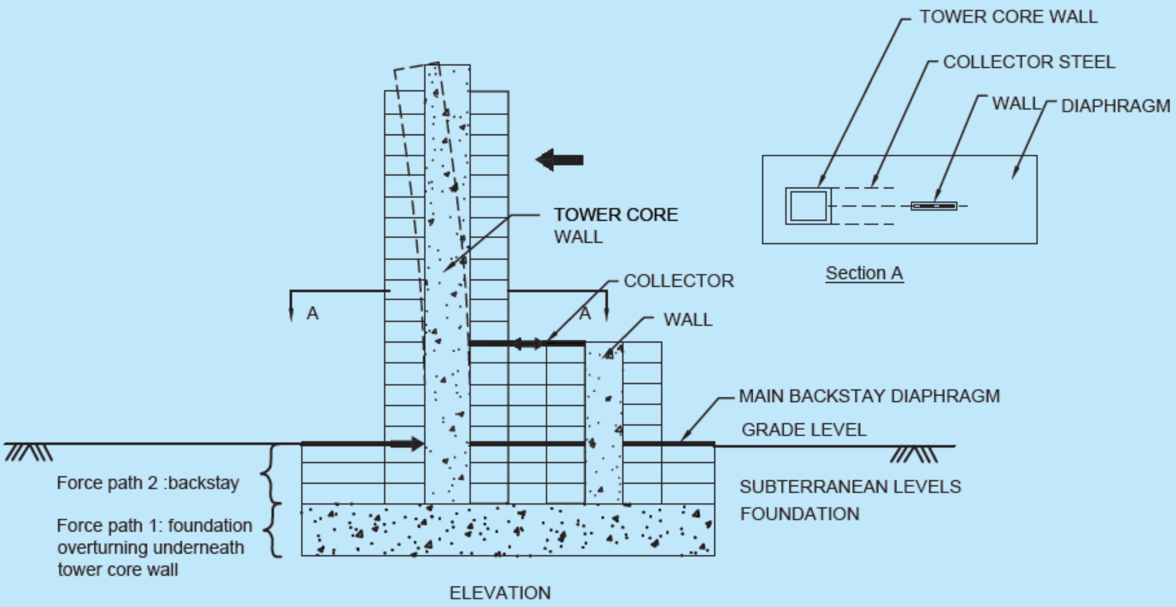
    i) Connections of diaphragms to vertical elements and to collectors; and

    ii) Collectors and their connections, including connections to vertical elements, of the seismic forces resisting system.

  3) When the lateral force resisting system of a tall building has plan irregularity of Type III (diaphragm discontinuity) as per **5** of Part C/Section 1 of this NBCS at the backstay diaphragm levels, collector elements and their connections to vertical elements shall be designed to resist seismic forces amplified by an over-strength factor of 2.5;

  4) Backstay diaphragm floor shall be at least 150 mm thick, with double mesh reinforcement not less than 0.25 percent of cross section area in each direction (including both layers of reinforcement steel); and

  5) Adequate measures shall be taken to prevent shear sliding failure at connections of diaphragm to structural walls; here, the inclination of the strut shall be taken as 45°. Additional reinforcements shall be provided to resist the shear force at the interface between diaphragm and structural walls.



a) **Path 1**: *Direct Load Path* through Tower Elements, and

b) **Path 2**: *Indirect Load Path* through Backstay Elements

FIG. 8 LOAD PATHS IN LATERAL OVERTURNING RESISTANCE OF TALL BUILDINGS WITH PODIUMS

E-8.1.3.3.2 *Structural walls*

a) Structural walls shown in Fig. 8 can sustain plastic hinges at the level of the backstay diaphragm also. Such walls shall also be designed and detailed for plastic hinge development at that level; and

b) All peripheral columns of the tower (irrespective of whether they are gravity columns or not) shall be provided with confinement reinforcements throughout the storeys adjoining (above and below) the backstay diaphragm level, as per the requirements of good practice [C-5(5)].

E-8.1.3.3.3 *Towers connected by common podium*

When buildings have two or more towers, they shall be designed considering the following:

a) Such buildings shall be modelled as separate towers as well as integral towers. The podium shall be designed based on the worst of the two results;

b) The estimation of natural period (for calculation of base shear) shall be based on individual building model;

c) In the integral tower modelling:

    1) directional effects for all worst possibilities (that is, tower shaking in the same and in the opposite directions) should be considered in the design load combinations; and

    2) equivalent static seismic forces can be used, provided they are scaled to match base overturning moments obtained from response spectrum analysis.

d) Where significant changes occur to mass or stiffness between the floors, the floor diaphragms of upper and lower levels shall be modelled to capture:

    1) diaphragm forces. Equivalent beam approach, finite element approach or strut and tie approach may be adopted to model the diaphragms; and

    2) potential cracking in the diaphragm by considering an upper bound and a lower bound axial stiffness. The lower and upper bound values of axial and flexural stiffnesses given in Table 13 for sensitivity analysis, may be considered for the cracked section properties, to arrive at the design level earthquake demand on the RC diaphragms.

e) Plan irregularities of Type I (torsion irregularity) and Type III (diaphragm discontinuity) as per **5** of Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS, shall not be present in the first topmost connected floor and the first floor of the tower above the connected floor;

f) Vertical irregularities of Type I (soft story) as per **5** of Part C/Sec 1 of this NBCS shall not be present in the first connected level and the level above it;

g) Topmost slab between the towers of connected podium shall be at least 150 mm thick with double mesh reinforcements not less than 0.25 percent of cross-sectional area in each direction;

h) Peripheral columns of the tower shall be provided with confinement reinforcements as per good practice [C-5(5)] at the first connected level and a level above;

j) Structural walls of the tower shall be provided with boundary elements as per good practice [C-5(5)] at the uppermost connected level and a level above; and

k) A transfer structure shall not be provided at the first connected floor.

E-8.2 Ductility

Notwithstanding any of the clauses of this standard, the designer shall take all measures to ensure that the building has:

a) sufficient ductility capacity;

b) acceptable energy dissipation mechanism; and

c) desirable sequence of initiation of ductile behaviour in members.

E-8.3 Frame Buildings

Frame structure for seismic design shall have at least two planar frames with minimum 3 bays in the direction where the lateral load resistance is provided by the moment frames.

E-8.4 Moment Frame — Structural Wall Systems

E-8.4.1 Frame structural wall systems shall be designed as dual systems as per 5 of Part C/Section 1 of this NBCS.

E-8.4.2 In a moment frame–structural wall system, the moment frame shall comply with the requirements of **E-8.3**, and the structural wall with the requirements of **E-8.5**. In addition, the moment frames and structural walls shall comply with the requirements of good practice [C-5(5)].

E-8.4.3 *Special Requirements for Seismic Zone* IV *and above*

Special moment frame and shear walls shall not be discontinued in lower storeys and supported on less stiff and brittle elements.

E-8.5 Structural Wall Systems

E-8.5.1 The thickness of structural wall shall not be less than 160 mm or $h_i/20$, whichever is larger.

E-8.5.2 Opening in structural walls and the associated coupling beams shall meet the following requirements:

a) For walls, when the opening size is less than 800 mm or one-third length of wall, whichever is lesser, in height or length, the influence of the opening may not be taken into account in the overall stiffness of the building;

b) For beams, the opening size shall be less than one-third of the height or length of beam and location of the opening shall be such that the top and bottom one-third of height of the coupling beam is not disturbed; and

c) In either case, all four sides of the opening shall be strengthened with additional reinforcements, and shall comply with requirements of good practice [C-5(5)]. Diameter of reinforcement bars used in this reinforcement shall not be less than 12 mm.

E-8.5.3 Gravity columns in structural wall buildings shall be designed as per requirements of deformation compatibility on non-seismic members given in **5** of Part C/Section 1 of this NBCS.

E-8.5.4 Beams carrying predominant vertical load shall not be supported on coupling beams. Also, columns or structural walls carrying predominant vertical load shall not be supported on coupling beam.

E-8.5.5 In a structural wall system, the structural wall shall comply with the requirements of good practice [C-5(5)].

E-8.5.6 Concentrated gravity loads applied on the wall above the design flexural section shall be assumed to be distributed over a width equal to the bearing width, plus a width on each side that increases at a slope of 2 vertical to 1 horizontal down to the design section, but:

a) not greater than the spacing of the concentrated loads; and

b) not extending beyond the edges of the wall panel.

E-8.5.7 Design of coupling beam shall comply with requirements of good practice [C-5(5)], unless it can be shown that loss of stiffness and strength of the coupling beams will not impair the vertical load carrying ability of the structure, the egress from the structure, or the integrity of non-structural components and their connections to the structure.

E-8.5.8 The nominal design shear stress shall be limited to $\tau_{c,\max}$ in structural walls that do not sustain tensile axial stress under any load combination, while the nominal design shear stress shall be limited to $0.5\tau_{c,\max}$ in structural walls under tension in any load combination and coupling beams in structural walls under factored design loads, where $\tau_{c,max}$ is as per Table 20 in the good practice [C-5(2)].

E-8.5.9 The amount and distribution of the minimum reinforcement in structural walls shall be as per good practice [C-5(5)].

E-8.5.10 At locations where yielding of longitudinal reinforcements is likely to occur as a result of lateral displacement, development length of longitudinal reinforcement shall be 1.25 times the values calculated for the bar yielded in tension, that is at a stress level of f_y.

E-8.5.11 The maximum longitudinal reinforcement ratio in coupling beam shall be as given in Table 14.

Table 14 Maximum Longitudinal Reinforcement in Coupling Beams (Each at Top and Bottom Surface)

(*Clause* E-8.5.11)

Sl No.	**Span to Depth Ratio**	**Maximum Reinforcement,** Percent
(1)	(2)	(3)
i)	$L_s/D \leq 1.0$	0.6
ii)	$1.0 \leq L_s/D < 2.0$	1.2
iii)	$2.0 \leq L_s/D$	1.5

E-8.5.12 *Requirements for Each Storey Resisting more than* 35 *percent of Design Base Shear*

Structural wall with a height-to-length ratio greater than 1.0 may be removed in any storey above, if it accounts for less than one-third of the storey shear strength. Further, the resulting structural system must not have any torsional irregularity as per **5** of Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS .

E-8.5.13 *Special Requirements for Seismic Zones IV and Above*

a) Structural walls shall be continuous to the base without being transferred in plane or out of plane at any level;

b) The minimum longitudinal reinforcement in structural walls shall not be less than 0.4 percent of gross cross-sectional area;

c) The minimum transverse reinforcement in structural walls shall not be less than 0.25 percent of gross cross-sectional area;

d) The reinforcements shall be distributed in two curtains in each direction;

e) Structural walls shall be fully embedded and anchored at their base in adequate basements or foundations, so that the wall does not rock. In this respect, walls supported by slabs or beams are not permitted; and

f) All openings in structural walls shall preferably be aligned vertically. Random openings, arranged irregularly, shall not be permitted in coupled walls, unless their influence is insignificant.

E-8.6 Flat Slab — Structural Wall Systems

In structures with flat slab system as gravity load carrying system, structural walls shall carry all lateral loads on the building, and column strips of the flat slab system shall not be included in the lateral load resisting system. All requirements related to structures with flat slabs mentioned in **5** of Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS shall be met with.

E-8.7 Framed Tube System, Tube-in-Tube System and Multiple Tube System

E-8.7.1 The plan shape of a tube-in-tube system shall be regular with a length to width ratio not more than 2 and, the inner tube shall be centered with the outer tube.

E-8.7.2 Reentrant corners and sharp changes to tubular form should be avoided.

E-8.7.3 Column spacing of framed tube shall preferably be not more than 5 m.

E-8.7.4 In a framed-tube system:

a) Area of corner column shall be 1 to 2 times that of internal column; and

b) Height to width ratio of the opening shall be similar to ratio of storey height to column spacing.

E-8.7.5 Due consideration shall be given to shear lag effects in the design of tube structures.

E-8.7.6 In Seismic Zones III and above:

a) Single span frame shall not be adopted; and

b) Axial compression ratio of columns shall be as per good practice [C-5(5)].

E-8.7.7 Beams carrying predominantly gravity load shall be directly supported on columns or on walls and not on frame beams.

E-8.7.8 The minimum requirements for reinforcement bar diameters in beams of moment frames of framed-tube structures are given in Table 15.

Table 15 Reinforcement Requirements in Beams

(*Clause* E-8.7.8)

All dimensions in millimetres.

Sl No.	Reinforcement Type	Seismic Zone	
		II	III and above
(1)	(2)	(3)	(4)
i)	Stirrup diameter	≥ 8	≥ 10
ii)	Stirrup spacing	≤ 150	≤ 100
iii)	Main (longitudinal) reinforcements	≥ 16	≥ 16

E-9 FOUNDATIONS

E-9.1 Load paths and mechanisms shall be ensured explicitly for transferring vertical and lateral loads between structure and soil system underneath.

E-9.2 A factor of safety of 1.5 shall be provided against overturning and sliding under, (a) unfactored design wind load, gravity load and other permanent imposed load; and (b) 2.5 times design earthquake load, unfactored gravity load and other permanent imposed load .

E-9.3 Geotechnical Investigations

E-9.3.1 All geotechnical investigations needed to establish the safety of the building shall be conducted including for liquefaction potential analysis, and estimation of soil spring constants and modulus of subgrade reaction.

E-9.3.2 For geotechnical investigations, the good practice [C-5(39)] shall be referred.

E-9.4 Depth of Foundation

The embedded depth of the building shall be at least 1/15 of height of building for raft foundation and 1/20 of the height of building for pile and piled raft foundation (excluding pile length). But, this requirement may be relaxed:

a) when the foundation rests on hard rock; or

b) when there is no uplift under any portion of the raft in any service load combination, and provided the minimum competent founding strata requirement is fulfilled.

E-9.5 Podium and basement roof slab shall be capable of transferring in-plane shear from the tower to the foundation.

E-9.6 Expansion joints shall preferably be avoided in basements of tall buildings. If provided such joints shall be suitably detailed for water tightness.

E-9.7 Modelling of Soil

E-9.7.1 While modelling raft foundations through spring constant or modulus of sub-grade reaction, zoned spring constants or zoned modulus of sub-grade reaction shall be utilized for design, at least for the case of (dead load + live load) condition. For design of rafts for buildings taller than 150 m, a soil-structure interaction study shall be conducted, using actual column loads and column locations to obtain the zoned spring constants.

E-9.7.2 For piled raft foundations designed with settlement reducing piles, soil-structure interaction study shall be conducted with actual column loads and column locations. This analysis shall be conducted at a minimum for combinations of following loads:

a) Dead;

b) Imposed;

c) Wind in X-direction;

d) Wind in Y-direction;

e) Seismic in X-direction; and

f) Seismic in Y-direction.

where X and Y are orthogonal axes in plan.

E-9.8 Settlements of Foundations

Maximum vertical settlement of raft or piled raft foundations under gravity loads shall comply with requirements of good practice [C-5(40)] and good practice [C-5(41)]. The maximum vertical settlement is limited to 125 mm in raft or raft-pile foundation subject to maximum angular distortion of raft not exceeding 1/500 and 50 mm in rock.

E-10 RECOMMENDATIONS FOR NON-STRUCTURAL ELEMENTS

The non-structural elements (NSEs) of tall buildings shall comply with all relevant existing national standards and guidelines as laid down by the various statutory and non-statutory bodies as well as the client/owner of the building.

E-11 MONITORING DEFORMATIONS IN BUILDINGS

E-11.1 Earthquake Shaking

All tall buildings in Seismic Zone V and tall buildings exceeding 150 m in Seismic Zone III and IV shall be instrumented with tri-axial accelerometers to capture translational and twisting behavior of buildings during strong earthquake shaking.

E-11.2 Wind Oscillations

Buildings over 150 m in height may be instrumented with anemometers and accelerometers to measure wind speed, acceleration and direction on top of the buildings.

E-11.3 Foundation Settlement and Pressure Measurement

E-11.3.1 Permanent settlement markers (at corners and center) shall be provided at raft top level and referenced to a permanent benchmark. Records of settlement shall be maintained till completion of the building and preferably even after completion.

E-11.3.2 Raft or Piled-raft shall be instrumented for monitoring long-term pressure imposed by soil on the raft, at appropriate number (at least 5) of pressure pads below the raft. Alternatively, piles can be instrumented with strain gauges at their top to measure the load on them.

LIST OF STANDARDS

The following list records those standards which are acceptable as ‘good practice’ and ‘accepted standards’ in the fulfilment of the requirements of this NBCS. The latest version of a standard shall be adopted at the time of enforcement of this NBCS. The standards listed may be used as a guide in conformance with the requirements of the referred clauses in this NBCS.

In the following list, the number appearing in the first column within parentheses indicates the number of the reference in this Part C/Section 5.

National Building Code Sectional Committee, CED 46

FOREWORD

This NBCS (Part C/Subsection 6A) covers the structural design aspects of steel structures in buildings.

This Section covers the use of hot-rolled structural steel sections and steel tubes in buildings. It covers the design by limit state method and plastic theory.

This Section was first published in 1970 and revised in 1983, 2005 and 2016 as a chapter of the National Building Code of India. In the second revision of 2005, the detailed design provisions were not included as IS 800 : 1984 'Code of practice for general construction in steel (*second revision*)' was under revision at that time. This Section, therefore, then referred to the 1984 version of IS 800 with the remarks that the latest version would prevail, as and when published. It, however, covered the philosophical aspects of limit state design which was being introduced in the revision of IS 800. IS 800 was subsequently revised and published as IS 800 : 2007 and hence, became the prevailing version for use under this Section. In the 2016 version of the Code, this Section was brought it in line with the revised version of IS 800 : 2007 read with its Amendment No. 1 and to take care of further improvements and incorporations required.

In the current revision, this publication has been renamed as National Building Construction Standards (NBCS).

This revision of the Section is intended to bring it in line with the revised version of IS 800 : 2026 (*under publication*) to take care of further improvements and incorporations required. In this revision, therefore, the following major modifications have been made:

a) The working stress design has been discontinued due to the increasing familiarity of designers with the limit state design of steel structures;

b) The table on tensile properties of structural steel products has been updated by including the latest Indian Standards relating to structural steels and aligning the corresponding provisions;

c) Fire-resistant steel as per IS 15103 : 2002 'Fire resistant steel — Specification', structural weather-resistant steels as per IS 11587 : 1986 'Structural weather resistant steels — Specification', and structural steels for buildings and structures with improved seismic resistance as per IS 15962 : 2012 'Structural steels for buildings and structures with improved seismic resistance — Specification' have been included in the table of tensile properties of structural steel products;

d) Provisions related to the requirement of temperature stress analysis have been updated;

e) Provisions related to the requirement of fire load have been updated;

f) Table 2 Limiting width thickness ratio of elements has been updated;

g) Provisions related to the consideration of second order effects have been updated;

h) Provisions related to design for earthquake loads relating to load and load combinations, various types of frames and connections in the critical zones of frames have been updated;

j) Provisions related to bracing connections have been updated;

k) Provisions related to fabrication procedures have been updated;

m) Certain terminologies, symbols and figures have been updated based on the changes incorporated;

n) Buckling class of cross section table has been updated;

p) Imperfection parameter for lateral torsional buckling of beam has been added;

q) A new clause on sustainable steel construction has been added. This provision covers the following:

    1) Requirements from Engineers, contractors and supply chain members;

    2) Sustainable design process by minimizing the materials, fabrication; and avoidance of maintenance; and

    3) Design for adaptability and deconstruction, etc.

r) The detailed provision relating to design of corrugated web girder have been introduced in Annex G.

The revised Section will enhance the confidence of designers, engineers, contractors, technical institutions, professional bodies and the industry and will open a new era in safe and economic construction in steel.

The provisions relating to using steel tubes in general building construction are based on IS 806 : 1968 'Code of practice for the use of steel tubes in general building construction', which is complementary to IS 800. The design using tubular steel in structural applications may be carried out using the limit state design provisions in this Section until IS 806 is revised as per the limit state design method.

The design of cold-formed steel members is based on the provisions of IS 801 : 1975 'Code of practice for use of cold formed light gauge steel structural members in general building construction'. The standard is currently under revision to be based on the limit state design practice. Until the revised IS 801 is published, the cold formed steel members may be designed using the current IS 801, based on the working stress method.

All standards, whether given herein above or cross-referred to in the main text of this section, are subject to revision. The parties to agreement based on this Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

For the purpose of deciding whether a particular requirement of this standard is complied with, the final value observed or calculated, expressing the result of a test or analysis, shall be rounded off in accordance with IS 2 : 2022 'Rules for rounding of numerical values (*second revision*)'. The number of significant places retained in the rounded off value should be the same as that of the specified value in this standard.

This Page has been Intentionally left blank

Important Explanatory Note for Users of the NBCS

In any Part/Section of this NBCS, where reference is made to **'good practice'** in relation to design, constructional procedures or other related information, and where reference is made to **'accepted standard'** in relation to material specification, testing, or other related information, the Indian Standards listed at the end of the Part/Section shall be used as a guide to the interpretation.

At the time of publication, the editions indicated in the standards were valid. All standards are subject to revision and parties to agreements based on any Part/ Section are encouraged to investigate the possibility of applying the most recent editions of the standards.

In the list of standards given at the end of a Part/Section, the number appearing within parentheses in the first column indicates the number of the reference of the standard in the Part/Section. For example:

a) Good practices [C-6A(1)] refers to the Indian Standard(s) give at serial number (1) of the list of standards given at the end of this Part C/Subsection 6A, that is, IS 786 : 1967 'Conversion factors and conversion tables (*first revision*)'.

NATIONAL BUILDING CONSTRUCTION STANDARDS

PART C STRUCTURAL DESIGN

SECTION 6 STEEL AND COMPOSITE CONSTRUCTION

SUBSECTION 6(A) STEEL

1 SCOPE

1.1 This NBCS (Part C/Subsection 6A) covers the structural design aspects of steel structures in buildings. This Section applies to general construction using hot rolled steel sections and steel tubes joined using riveting, bolting, and welding. Cold formed light gauge steel sections are covered in separate standards. This Section covers the design by limit state method and plastic theory.

1.2 This Section gives only general guidance as regards to the various loads to be considered in the design. For the actual loads, such as dead, imposed, snow, wind and earthquake loads and load combinations to be used, reference may be made to Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS.

1.3 Fabrication and erection requirements covered in this Section are general and the minimum necessary quality of material and workmanship consistent with assumptions in the design rules. The actual requirements may be further developed as per other standards or the project specification, the type of structure and the method of construction.

1.4 For seismic design, recommendations pertaining to steel frames only are covered in this section. For more detailed information on seismic design of other structural and non-structural components, reference be made to **5** of Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS and other special publications on the subject.

2 –

NOTE — This clause is intentionally left blank.

3 TERMINOLOGY

For the purpose of this standard, the following definitions shall apply.

3.1 Accidental Loads — Loads due to explosion, impact of vehicles, or other rare loads for which the structure is susceptible as per user.

3.2 Accompanying Load — Imposed load acting along with leading imposed load but Causing action/deflection lesser than the leading load.

3.3 Action Effect or Load Effect — Internal response of a structural element, including axial force, shear force, bending moment, and torsional moment, resulting from applied external loads, temperature variations, and other environmental influences such as seismic activity, settlement effects, and residual stresses.

3.4 Action — The primary cause for stress or deformations in a structure such as dead, imposed, wind, seismic or temperature loads.

3.5 Actual Length — The distance measured from centre to centre of intersection points with supporting members, applicable to beams, trusses, or other structural elements. In the case of a cantilevered member, it refers to the full projection from the fixed support.

3.6 Beam — A member subjected predominantly to bending.

3.7 Bearing Type Connection — A connection made using bolts in 'snug-tight' condition, or rivets where the load is transferred by bearing of bolts or rivets against plate inside the bolt hole.

3.8 Braced Member — A member in which the relative transverse displacement is effectively prevented by bracing.

3.9 Brittle Cladding — Claddings, such as cement fibre boards which get damaged before undergoing considerable deformation.

3.10 Buckling Load — The load at which an element, a member or a structure as a whole, either collapses in service or buckles in a load test and develops excessive lateral (out of plane) deformation or instability.

3.11 Buckling Strength or Resistance — Force or moment, which a member can withstand without buckling.

3.12 Built-up Section — A member fabricated by interconnecting more than one element to form a compound section acting as a single member.

3.13 Camber — Intentionally introduced pre-curving (usually upwards) in a system, member or any portion of a member with respect to the straight line joining the end points in place. Frequently, camber is introduced to compensate for deflections at a specific level of loads.

3.14 Characteristic Load (Action) — The value of specified load (action), above which not more than a specified percentage (usually 5 percent) of samples of corresponding load are expected to be encountered.

3.15 Characteristic Yield/Ultimate Stress — The minimum value of stress, below which not more than a specified percentage (usually 5 percent) of corresponding stresses of samples tested are expected to occur.

3.16 Column — A member in upright (vertical) position which supports a roof or floor system and predominantly subjected to compression.

3.17 Compact Section — A cross section, which can develop plastic moment, but has inadequate plastic rotation capacity needed for formation of a plastic collapse mechanism of the member or structure.

3.18 Constant Stress Range — The amplitude between which the stress ranges under cyclic loading is assumed to be constant during the life of the structure or a structural element.

3.19 Corrosion — An electrochemical process over the surface of steel, leading to oxidation of the metal.

3.20 Crane Load — The horizontal and vertical forces exerted by a crane on a structure, including dynamic effects due to crane movement, acceleration, and braking caused by its due to its self-weight and load lifted.

3.21 Cumulative Fatigue — Total damage due to fatigue loading of varying stress ranges.

3.22 Cut-off Limit — The stress range, corresponding to the particular detail, below which cyclic loading need not be considered in cumulative fatigue damage evaluation (corresponds to 10^8 number of cycles in most cases).

3.23 Dead Loads — The self-weights of all permanent constructions and installations including the self-weight of all walls, partitions, floors, roofs, and other permanent fixtures acting on a member.

3.24 Deflection — The deviation from the standard position of a member or structure.

3.25 Design Life — Time period for which a structure or a structural element is required to perform its function without damage.

3.26 Design Load/Factored Load — A load value obtained by multiplying the characteristic load with the partial safety factor for loads.

3.27 Design Spectrum — Frequency distribution of the stress ranges from all the nominal loading events during the design life (stress spectrum).

3.28 Detail Category — Designation given to a particular detail to indicate the S-N curve to be used in fatigue assessment.

3.29 Discontinuity — A sudden change in cross section of a loaded member, causing a stress concentration at the location.

3.30 Ductility — The property of the material or a structure indicating the extent to which it can deform beyond the limit of yield deformation before failure or fracture. The ratio of ultimate to yield deformation is usually termed as ductility.

3.31 Durability — The ability of a material to resist deterioration over long periods of time.

3.32 Earthquake effects — The inertia forces and relative deformations induced in a structure due to the ground shaking during an earthquake.

3.33 Edge Distance — Distance from the centre of a fastener hole to the nearest edge of an element measured perpendicular to the direction of load transfer.

3.34 Effective Lateral Restraint — Restraint that produces sufficient resistance to prevent deformation in the lateral direction.

3.35 Effective Length — Actual length of a member between points of effective restraint or effective restraint and free end, multiplied by a factor to take account of the end conditions in buckling strength calculations.

3.36 Elastic Cladding — Claddings, such as metal sheets that can undergo considerable deformation without damage.

3.37 Elastic Critical Moment — The elastic moment, which initiates lateral-torsional buckling of a laterally unsupported beam.

3.38 Elastic Design — Design, which assumes elastic behaviour of materials throughout the service load range.

3.39 Elastic Limit — The stress below which the material regains its original size and shape when the load is removed. In steel design, it is taken as the yield stress.

3.40 End Distance — Distance from the centre of a fastener hole to the edge of an element measured parallel to the direction of load transfer.

3.41 Erection Loads — The actions (loads and deformations) experienced by the structure exclusively during erection.

3.42 Erection Tolerance — Amount of deviation related to the plumbness, alignment, and level of the element as a whole in the erected position. The deviations are determined by considering the locations of the ends of the element.

3.43 Exposed Surface Area to Mass Ratio — The ratio of the surface area exposed to the fire (in mm^2) to the mass of steel (in kg).

NOTE — In the case of members with fire protection material applied, the exposed surface area is to be taken as the internal surface area of the fire protection material.

3.44 Fabrication Tolerance — Amount of deviation allowed in the nominal dimensions and geometry in fabrication activities, such as cutting to length, finishing of ends, cutting of bevel angles, etc.

3.45 Factor of Safety — The factor by which the yield stress of the material of a member is divided to arrive at the permissible stress in the material.

3.46 Fatigue — Damage caused by repeated fluctuations of stress, leading to progressive cracking of a structural element.

3.47 Fatigue Loading — Set of nominal loading events, cyclic in nature, described by the distribution of the loads, their magnitudes and the numbers of applications in each nominal loading event.

3.48 Fatigue Strength — The stress range for a category of detail, depending upon the number of cycles it is required to withstand during design life.

3.49 Fire Exposure Condition

3.49.1 *Three-Sided Fire Exposure Condition* — Steel member incorporated in or in contact with a concrete or masonry floor or wall (at least against on surface); and

NOTES

1 Three-sided fire exposure condition is to be considered separately unless otherwise specified (*see* **22.9**).

2 Members with more than one face in contact with a concrete or masonry floor or wall may be treated as three-sided fire exposure.

3.49.2 *Four-Sided Fire Exposure Condition* — Steel member, which may be exposed to fire on all sides.

3.50 Fire Protection System — The fire protection material and its method of attachment to the steel member.

3.51 Fire Resistance — The ability of an element, component or structure, to fulfil for a stated period of time, the required stability, integrity, thermal insulation and/or other expected performance specified in a standard fire test.

3.52 Fire Resistance Level — The fire resistance grading period for a structural element or system, in minutes, which is required to be attained in the standard fire test.

3.53 Flexural Stiffness — Stiffness of a member against rotation as evaluated by the value of bending deformation moment required to cause a unit rotation while all other degrees of freedom of the joints of the member except the rotated one are assumed to be restrained.

3.54 Friction Type Connection — Connection effected by using pre-tensioned high strength bolts where shear force transfer is due to mobilization of friction between the connected plates due to clamping force developed at the interface of connected plates by the bolt pre-tension.

3.55 Gauge — The spacing between adjacent parallel lines of fasteners, transverse to the direction of load/stress.

3.56 Gravity Load — Loads arising due to gravitational effects.

3.57 Gusset Plate — The plate to which the members intersecting at a joint are connected.

3.58 High Shear — High shear condition is caused when the actual shear due to factored load is greater than a certain fraction of design shear resistance (*see* **16.2.2**).

3.59 Imposed (Live) Load — The load assumed to be produced by the intended use or occupancy including distributed, concentrated, impact, vibration and snow loads but excluding, wind, earthquake and temperature effects.

3.60 Instability — The phenomenon which disables an element, member or a structure to carry further load due to excessive deflection lateral to the direction of loading and vanishing stiffness.

3.61 Lateral Restraint for a Beam — *See* **3.34**.

3.62 Leading Imposed Load — Imposed load causing higher action and/or deflection.

3.63 Limit State — Any limiting condition beyond which the structure ceases to fulfill its intended function (*see* also **3.86**).

3.64 Live Load — *See* **3.59**.

3.65 Load — An externally applied force or action (*see also* **3.4**).

3.66 Main Member — A structural member, which is primarily responsible for carrying and distributing the applied load or action.

3.67 Mill Tolerance — Amount of variation allowed from the nominal dimensions and geometry, with respect to cross sectional area, non-parallelism of flanges, and out of straightness such as sweep or camber, in a product, as manufactured in a steel mill.

3.68 Normal Stress — Stress component acting normal to the face, plane or section.

3.69 Partial Safety Factor — The factor normally greater than unity by which either the loads (actions) are multiplied or the resistances are divided to obtain the design values.

3.70 Period of Structural Adequacy under Fire — The time (t), in minutes, for the member to reach the limit state of structural inadequacy in a standard fire test.

3.71 Permissible Stress — When a structure is being designed by the working stress method, the maximum stress that is permitted to be experienced in elements, members or structures under the nominal/service load (action).

3.72 Pitch — The centre to centre distance between individual fasteners in a line, in the direction of load/stress.

3.73 Plastic Collapse — The failure stage at which sufficient number of plastic hinges have formed due to the loads (actions) in a structure leading to a failure mechanism.

3.74 Plastic Design — Design against the limit state of plastic collapse.

3.75 Plastic Hinge — A yielding zone with significant inelastic rotation, which forms in a member, when the plastic moment is reached at a section.

3.76 Plastic Moment — Moment capacity of a cross section when the entire cross section has yielded due to bending moment.

3.77 Plastic Section — Cross section, which can develop a plastic hinge and sustain plastic moment over sufficient plastic rotation required for formation of plastic failure mechanism of the member or structure.

3.78 Poisson’s Ratio — The absolute value of the ratio of lateral strain to longitudinal strain under uniaxial loading.

3.79 Proof Stress — The stress to which high strength friction grip (HSFG) bolts are pre-tensioned.

3.80 Proof Testing — The application of test loads to a structure, sub-structure, member or connection to ascertain the structural characteristics of only that specific unit.

3.81 Prototype Testing — Testing of structure, sub-structure, members or connections to ascertain the structural characteristics of that class of structures, sub-structures, members or connections that are nominally identical (full scale) to the units tested.

3.82 Prying Force — Additional tensile force developed in a bolt as a result of the flexing of a connection component such as a beam end plate or leg of an angle.

3.83 Rotation — The change in angle at a joint between the original orientation of two linear member and their final position under loading.

3.84 Secondary Member — Member which is provided for overall stability and or for restraining the main members from buckling or similar modes of failure.

3.85 Semi-compact Section — Cross section, which can attain the yield moment, but not the plastic moment before failure by plate buckling.

3.86 Serviceability Limit State — A limit state of acceptable service condition exceedance of which causes serviceability failure.

3.87 Shear Force — The in-plane force at any transverse cross section of a straight member of a column or beam.

3.88 Shear lag — The in plane shear deformation effect by which concentrated forces tangential to the surface of a plate gets distributed over the entire section perpendicular to the load over a finite length of the plate along the direction of the load.

3.89 Shear Stress — The stress component acting parallel to a face, plane or cross section.

3.90 Slender Section — Cross section in which the elements buckle locally before reaching yield moment.

3.91 Slenderness Ratio — The ratio of the effective length of a member to the radius of gyration of the cross section about the axis under consideration.

3.92 Slip Resistance — Limit shear that can be applied in a friction grip connection before slip occurs.

3.93 S-N Curve — The curve defining the relationship between the number of stress cycles to failure (N_{sc}) at a constant stress range (S_c), during fatigue loading of a structure.

3.94 Snow Load — Load on a structure due to the accumulation of snow and ice on surfaces such as roof.

3.95 Snug Tight — The tightness of a bolt achieved by a few impacts of an impact wrench or by the full effort of a person using a standard spanner.

3.96 Stability Limit State — A limit state corresponding to the loss of static equilibrium of a structure by excessive deflection transverse to the direction of predominant loads.

3.97 Stickability — The ability of the fire protection system to remain in place as the member deflects under load during a fire test.

3.98 Stiffener — An element used to retain or prevent the out-of-plane deformations of plates.

3.99 Strain — Deformation per unit length or unit angle.

3.100 Strain Hardening — The phenomenon of increase in stress with increase in strain beyond yielding.

3.101 Strength — Resistance to failure by yielding or buckling.

3.102 Strength Limit State — A limit state of collapse or loss of structural integrity.

3.103 Stress — The internal force per unit area of the original cross section.

3.104 Stress Analysis — The analysis of the internal force and stress condition in an element, member or structure.

3.105 Stress Cycle Counting — Sum of individual stress cycles from stress history arrived at using any rational method.

3.106 Stress Range — Algebraic difference between two extremes of stresses in a cycle of loading.

3.107 Stress Spectrum — Histogram of stress cycles produced by a nominal loading event design spectrum, during design life.

3.108 Structural Adequacy for Fire — The ability of the member to carry the test load exposed to the standard fire test.

3.109 Structural Analysis — The analysis of stress, strain, and deflection characteristics of a structure.

3.110 Strut — A compression member, which may be oriented in any direction.

3.111 Sway — The lateral deflection of a frame.

3.112 Sway Member — A member in which the transverse displacement of one end, relative to the other is not effectively prevented.

3.113 Tensile Stress — The characteristic stress corresponding to rupture in tension, specified for the grade of steel in the appropriate Indian Standard, as listed in Table 1.

3.114 Test Load — The factored load, equivalent to a specified load combination appropriate for the type of test being performed.

3.115 Transverse — Direction along the stronger axes of the cross section of the member.

3.116 Ultimate Limit State — The state which, if exceeded can cause collapse of a part or the whole of the structure.

3.117 Ultimate Stress — *See* **3.113**.

3.118 Wind Loads — Load experienced by member or structure due to wind pressure acting on the surfaces.

3.119 Yield Stress — The characteristic stress of the material in tension before the elastic limit of the material is exceeded, as specified in the appropriate Indian Standard, as listed in Table 1.

3.120 Terms Relating to Sustainable Steel Design

3.120.1 *Embodied Carbon* — Life-cycle greenhouse gas emissions (expressed as carbon dioxide equivalents – CO2e) that occur during the manufacture and transport of construction materials and components, as well as the construction process itself and end-of-life aspects of the building.

NOTE — In recent years, the term embodied carbon of construction materials and products has become synonymous with the term carbon footprint.

3.120.2 *Deconstruction* (*or Disassembly, or Demounting*) — Deconstruction is the process of taking a building apart into its components in such a way that they can be more readily reused; it minimizes the destructive aspects of the process of removing buildings, preserving components and materials not wasting them, and treating them as a resource.

3.120.3 *Design for Deconstruction* (*DfD*) — Designing for deconstruction is considering, at the design stage, how a building can be taken apart.

3.120.4 *Environmental Product Declaration* (*EPD*) — An EPD communicates verifiable, accurate, non-misleading environmental information for products and their applications; EPD information is expressed in information modules, which allow easy organization and expression of data packages throughout the life cycle of the product.

3.120.5 *Material Efficiency* — Optimizing the use of the steel by avoiding waste during fabrication and avoiding over specification of steel in the design.

3.120.6 *Recycling* — Steel involves re-melting of scrap to form new semi-finished products.

3.120.7 *Responsible Sourcing* — Management of sustainable development in the provision or procurement of a product.

3.120.8 *Reuse* — Use of previously used components with little or no reprocessing, largely in their original form; they may be reused for the original function (a conventional reuse scenario), or repurposed.

3.120.9 *Sustainable Development* — An enduring, balanced approach to economic activity, environmental responsibility and social progress.

3.120.10 *Traceability* — Ability to trace the history, application or location of an object.

4 SYMBOLS

For the purpose of this Subsection, the symbols (other than those used for load categorization) given in Annex A are applicable.

5 UNITS

For the purpose of design calculations the following units are recommended:

a) forces and loads, in kN, kN/m, kN/m^2;

b) unit mass, in kg/m^3;

c) unit weight, in kN/m^3;

d) stresses and strengths, in N/mm^2 (= MN/m^2 or MPa); and

e) moments (bending, etc), in kNm.

For conversion of one system of units to another system, [C-6A(1)] may be referred.

6 STANDARD DIMENSIONS, FORM AND WEIGHT

The dimensions, form, weight, tolerances of all rolled shapes, all rivets, bolts, nuts, studs, and welds and other members used in any steel structure shall conform to accepted standards [C-6A(2)], wherever applicable.

7 PLANS AND DRAWINGS

7.1 Plans, drawings and stress sheet shall be prepared according to accepted standards [C-6A(3)].

7.1.1 *Plans*

The plans (design drawings) shall show the sizes, sections, and the relative locations of the various members. Floor levels, column centres, and offsets shall be dimensioned. Plans shall be drawn to a scale large enough to convey the information adequately. Plans shall indicate the type of construction to be employed; and shall be supplemented by such data on the assumed loads, shears, moments and axial forces to be resisted by all members and their connections, as may be required for the proper preparation of shop drawings. Any special precaution to be taken in the erection of structure, from the design consideration shall also be indicated in the drawing.

7.1.2 *Shop Drawings*

Shop drawings, giving complete information necessary for the fabrication of the component parts of the structure including the location, type, size, length and detail of all welds and fasteners shall be prepared in advance of the actual fabrication. They shall clearly distinguish between shop and field rivets, bolts and welds. For additional information to be included on drawings for designs based on the use of welding, reference shall be made to appropriate Indian Standards. Shop drawings shall be made in conformity with accepted standard [C-6A(4)]. A marking diagram allotting distinct identification marks to each separate part of steel work shall be prepared. The diagram shall be sufficient to ensure convenient assembly and erection at site.

7.2 Symbols used for welding on plans and shop drawings shall be according to good practice [C-6A(5)].

8 CONVENTION FOR MEMBER AXES

Unless otherwise specified convention used for member axes is as follows (Fig. 1):

a) *x-x* along the member;

b) *y-y* an axis of the cross section:

  1) perpendicular to the flanges; and

  2) perpendicular to the smaller leg in an angle section.

c) *z-z* an axis of the cross-section:

    1) axis parallel to flanges; and
    2) axis parallel to smaller leg in angle section.
- d) *u-u* major axis (when it does not coincide with *z-z* axis); and
- e) *v-v* minor axis (when it does not coincide with *y-y* axis).

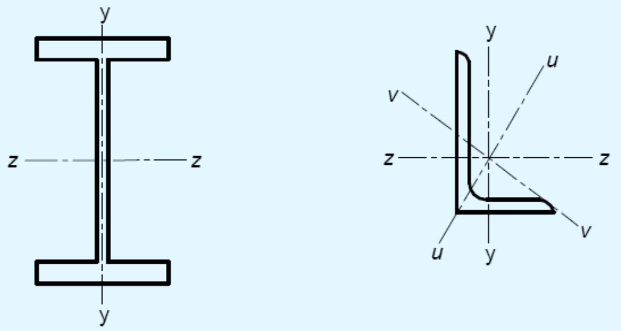

FIG. 1 AXES OF MEMBERS

9 MATERIALS

9.1 General

The material properties given in this clause are nominal values, to be accepted as characteristic values in design calculations.

9.2 Structural Steel

9.2.1 The provisions in this Section are applicable to the steels commonly used in steel construction namely, structural mild steel and high tensile structural steel.

9.2.2 All the structural steel used in general construction, coming under the purview of this standard shall before fabrication conform to accepted standard [C-6A(6)].

9.2.3 Structural steel other than those specified in 9.2.2 may also be used provided that the permissible stresses and other design provisions are suitably modified and the steel is also suitable for the type of fabrication adopted.

9.2.3.1 Steel that is not supported by mill test result may be used only in unimportant members and details, where their properties such as ductility and weldability would not affect the performance requirements of the members and the structure as a whole.

However, such steels may be used in structural system after confirming their quality by carrying out appropriate tests in accordance with the method specified in accepted standard [C-6A(7)].

9.2.4 *Properties*

The properties of structural steel for use in design may be taken as given in 9.2.4.1 and 9.2.4.2.

9.2.4.1 Physical properties of structural steel irrespective of its grade may be taken as:

- a) unit mass of steel, ρ = 7 850 kg/m^3;
- b) modulus of elasticity, $E = 2.0 \times 10^5$ N/mm^2 (MPa);
- c) Poisson's ratio, $\mu = 0.3$;
- d) modulus of rigidity, $G = 0.769 \times 10^5$ N/mm^2 (MPa); and

e) coefficient of thermal expansion $\alpha_t = 12 \times 10^{-6}$ /°C

9.2.4.2 *Mechanical properties of structural steel*

The principal mechanical properties of the structural steel important in design are the yield stress, f_y; the tensile or ultimate stress, f_u; the maximum percent elongation on a standard gauge length and notch toughness. Except for notch toughness, the other properties are determined by conducting tensile tests on samples cut from the plates, sections, etc, in accordance with accepted standard [C-6A(7)]. Commonly used properties for the common steel products of different specifications are summarized in Table 1.

9.2.4.2.1 *Steel tubes* — Steel tubes used in building construction shall be hot finished tubes conforming to the requirements specified in accepted standard [C-6A(8)].

9.2.4.2.2 Tubes made by other than hot finishing processes, or which have been subjected to cold working, shall be regarded as hot finished if they have subsequently been heat-treated and are supplied in the normalized conditions.

9.2.4.3 *Electrodes* — The electrodes used for welding steel tubes shall conform to the requirements of accepted standard [C-6A(9)] or [C-6A(10)], as appropriate.

9.3 Rivets

9.3.1 Rivets shall be manufactured from steel conforming to accepted standard [C-6A(11)]. They may also be manufactured from steel conforming to accepted standard [C-6A(6)] provided that the steel meets the requirements given in accepted standard [C-6A(12)].

9.3.2 Rivets shall conform to accepted standards [C-6A(13)] as appropriate.

9.3.3 *High Tensile Steel Rivets*

High tensile steel rivets, shall be manufactured from steel conforming to accepted standard [C-6A(12)].

9.4 Bolts, Nuts and Washers

Bolts, nuts and washers shall conform as appropriate to accepted standards [C-6A(14)]. The recommendations in good practice [C-6A(15)] shall be followed.

9.5 Steel Casting

Steel casting shall conform to accepted standard [C-6A(16)] or accepted standard [C-6A(17)].

9.6 Welding Consumable

9.6.1 Covered electrodes shall conform to accepted standard [C-6A(9)] or [C-6A(10)], as appropriate.

9.6.2 Filler rods and wires for gas welding shall conform to accepted standard [C-6A(18)].

9.6.3 The supply of solid filler wires for submerged arc welding of structural steels shall conform to accepted standard [C-6A(19)].

9.6.4 The bare wire electrodes for submerged arc welding and the combination of wire and flux shall satisfy the requirements of accepted standard [C-6A(20)].

9.6.5 Filler rods and bare electrodes for gas shielded metal arc welding shall conform to accepted standards [C-6A(21)], as appropriate.

9.7 Other Materials

Other materials used in association with structural steel work shall conform to appropriate Indian standards.

NOTE — Percentage of elongation shall be taken over the gauge length of 5.65 $\sqrt{S_0}$, where S_0 = original cross-sectional area of the test specimen.

---

[1] Stress at 0.2 percent non-proportional elongation, Min.

[2] For Grade A sections and bars, the upper limit of the tensile strength may be 550 MPa or as agreed between the purchaser and the manufacturer/the supplier.

[3] For full thickness flat test pieces with width 25 mm and gauge length 200 mm, the minimum elongation (percent) may be reduced as per specified in good practice [C-6A(**29**)].

10 GENERAL DESIGN REQUIREMENTS

10.1 Basis for Design

10.1.1 *Design Objective*

The objective of design is the achievement of an acceptable probability that structures will perform satisfactorily for the intended purpose during the design life. With an appropriate degree of safety, they should sustain all the loads and deformations, during construction and use and have adequate resistance to certain expected accidental loads and fire. Structure should be stable and have alternate load paths to prevent disproportionate overall collapse under accidental loading.

10.1.2 *Methods of Design*

Structure and its elements shall normally, be designed by the limit state method. Account should be taken of accepted theories, experimental information and experience and the need to design for durability. Calculations alone may not produce safe, serviceable and durable structures. Suitable materials, quality control, adequate detailing and good supervision are equally important.

10.1.3 *Design Process*

Structural design, including design for durability, construction and use should be considered as a whole. The realization of design objectives requires compliance with clearly defined standards for materials, fabrication, erection and in-service maintenance.

10.2 Loads and Forces

10.2.1 For the purpose of designing any element, member or a structure, the following loads (actions) and their effects shall be taken into account, where applicable, with partial safety factors for loads and their combinations given in Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS (*see* **12.3.3**).

a) Dead loads;

b) Imposed loads (imposed load, crane load, snow load, dust load, wave load, earth pressures, etc);

c) Wind loads;

d) Earthquake effects;

e) Fire Load, forces induced due to restraint against expansion during a fire;

f) Erection loads;

g) Accidental loads such as those due to blasts, impact of vehicles, etc; and

h) Secondary effects due to contraction or expansion resulting from temperature changes, differential settlements of the structure as a whole or of its components, eccentric connections, rigidity of joints differing from design assumptions.

10.2.1.1 Dead loads should be assumed in design as specified in **2** of Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS.

10.2.1.2 Imposed loads for different types of occupancy and function of structures shall be taken as recommended in **3** of Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS. Imposed loads arising from equipment, such as cranes and machines should be assumed in design as per manufacturers/suppliers data (*see* **10.6.4**). Snow load shall be taken as per in **6** of Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS.

10.2.1.3 Wind loads on structures shall be taken as per the recommendations of **4** of Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS.

10.2.1.4 Earthquake effects shall be assumed as per the recommendations of **5** of Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS.

10.2.1.5 The fire loads, erection loads and temperature effects shall be considered as specified in **10.3**, **10.4** and **10.5**, respectively.

10.3 Fire Loads

During a fire, the structural members around the fire experience higher temperatures. This causes expansion in members that is restrained by rest of the structure, inducing forces in the members. Simultaneously, due to high temperature both strength and stiffness of the members experiencing the higher temperature degrade. The forces in members during fire including that due to dead load and imposed load are checked against the reduced capacity of the members. As it is an extreme event, the design is done for loads without extra partial safety factors. The imposed load is taken as 100 percent of the characteristic Imposed loads in case of storage areas and otherwise taken as 50 percent of the characteristic Imposed load value, during fire.

Due to proper fire protection, the temperature felt by the members may be less than the ambient temperature, and this may be taken into consideration in evaluating temperature effects due to fire.

10.4 Erection Loads

All loads required to be carried by the structure or any part of it due to storage or positioning of construction material and erection equipment, including all loads due to operation of such equipment shall be considered as erection loads. Proper provision shall be made, including temporary bracings, to take care of all stresses developed during erection. Dead load, wind load and also such parts of the imposed load as would be imposed on the structure during the period of erection shall be taken as acting together with the erection loads. The structure as a whole and all parts of the structure in conjunction with the temporary bracings shall be capable of sustaining these loads during erection.

10.5 Temperature Effects

10.5.1 Expansion and contraction due to changes in temperature of the members and elements of a structure shall be considered and adequate provision made for such effect.

10.5.2 The temperature range varies for different localities and under different diurnal and seasonal conditions. The absolute maximum and minimum temperatures, which may be expected at the site, may be obtained from the Indian Metrological Department and used in assessing the maximum variations of temperature for which provision for expansion and contraction has to be made in the structure.

10.5.3 The range of variation in temperature of the building materials may be appreciably greater or lesser than the variation of air temperature and is influenced by the condition of exposure and the rate at which the materials composing the structure absorb or radiate heat. This difference in temperature variations of the material and air shall be given due consideration. The effect of differential temperature within an element or member, due to part exposure to direct sunlight shall also be considered.

10.5.4 The coefficient of thermal expansion for steel is as given in **9.2.4.1**(e).

10.6 Load Combinations

10.6.1 Load combinations for design purposes shall be those that produce maximum forces and effects and, consequently maximum stresses and deformations. The combination of loads with appropriate partial safety factors may be as per Part C/Section 1 of this NBCS.

NOTE — In the case of structures supporting cranes, imposed loads shall include the crane effects as given in **10.6.4**.

10.6.2 Wind load and earthquake effects shall not be assumed to act simultaneously. The effect of each shall be considered separately.

10.6.3 The effect of cranes to be considered under imposed loads shall include the vertical loads, eccentricity effects induced by the vertical loads, impact factors, lateral (surge) and longitudinal (horizontal) thrusts, not acting simultaneously across and along the crane rail, respectively [*see* **3** of Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS].

10.6.4 The crane loads and their combinations to be considered shall be as indicated by the customer. In the absence of any specific indications, the load combinations shall be in accordance with the provisions in **3** of Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS or as given below:

a) Vertical loads with full impact from one loaded crane or two cranes in case of tandem operation, together with vertical loads without impact from as many loaded cranes as may be positioned for maximum effect, along with maximum horizontal thrust from one crane only or two in case of tandem operation;

b) Loads as specified in **10.6.4**(a), subject to cranes in maximum of any two bays of the building cross section shall be considered for multi-bay multi-crane gantries;

c) The longitudinal thrust on a crane track rail shall be considered for a maximum of two loaded cranes on the track; and

d) Lateral thrust (surge) and longitudinal thrust acting across and along the crane rail, respectively, shall be assumed not to act simultaneously. The effect of each force, shall however be investigated separately.

10.6.5 While investigating the effect of earthquake, the resulting effect from dead loads of all cranes parked in each bay, positioned to cause maximum effect shall be considered.

10.6.6 The crane runway girders supporting bumpers shall be checked for bumper impact loads also, as specified by the manufacturers.

10.6.7 Stresses developed due to secondary effects such as handling; erection, temperature and settlement of foundations, if any, shall be appropriately added to the stresses calculated from the combination of loads stated in **10.6.1**, with appropriate partial safety factors.

10.7 Geometrical Properties

10.7.1 *General*

The geometrical properties of the gross and the effective cross sections of a member or part thereof, shall be calculated on the following basis:

a) the properties of the gross cross section shall be calculated from the specified size of the member or part thereof or read from appropriate table; and

b) the properties of the effective cross section shall be calculated by deducting from the area of the gross cross section, in the following:

1) The sectional area in excess of effective plate width, in case of slender sections [*see* **10.8.2 (d)**]; and

2) The sectional areas of all holes in the section except for parts in compression. In case of punched holes, hole size 2 mm in excess of the actual diameter may be deducted.

10.8 Classification of Cross Sections

10.8.1 Plate elements of a cross section may buckle locally due to compressive stresses. The local buckling can be avoided before the limit state is achieved by limiting the width to thickness ratio of each element of a cross section subjected to compression due to axial force, moment or shear.

10.8.1.1 When plastic analysis is used, the members shall be capable of forming plastic hinges with sufficient rotation capacity (ductility) without local buckling, to enable the redistribution of bending moment required before formation of the failure mechanism.

10.8.1.2 When elastic analysis is used, the member shall be capable of developing the yield stress under compression without local buckling.

10.8.2 On basis of the above, four classes of sections are defined as follows:

a) *Class* 1 (*Plastic*) — Cross sections, which can develop plastic hinges and have the rotation capacity required for failure of the structure by formation of plastic mechanism. The width to thickness ratio of plate elements shall be less than that specified under class 1 (Plastic), in Table 2;

b) *Class* 2 (*Compact*) — Cross sections, which can develop plastic moment of resistance, but have inadequate plastic hinge rotation capacity for formation of plastic mechanism, due to local buckling. The width to thickness ratio of plate elements shall be less than that specified under class 2 (compact), but greater than that specified under class 1 (plastic), in Table 2;

c) *Class* 3 (*Semi-compact*) — Cross sections, in which the extreme fiber in compression can reach yield stress, but cannot develop the plastic moment of resistance, due to local buckling. The width to thickness ratio of plate elements shall be less than that specified under class 3 (semi-compact), but greater than that specified under class 2 (compact), in Table 2; and

d) *Class* 4 (*Slender*) — Cross sections in which the elements buckle locally even before reaching yield stress. The width to thickness ratio of plate elements shall be greater than that specified under class 3 (semi-compact), in Table 2. In such cases, the effective sections for design shall be calculated either by following the provisions of good practice [C-6A(35)] to account for the post-local-buckling strength or by conservatively deducting width of the compression plate element in excess of the semi-compact section limit [*see* Fig. 2(C)].

The design of slender web elements in flexural members may be done as given in **15.2.1.1** for flexure and **15.4.2.2** for shear.

When different elements of a cross section fall under different classes, the section shall be classified as governed by the most critical element.

The maximum value of limiting width to thickness ratios of elements for different classifications of sections are given in Fig. 2(A). The effective section in case of class 4 (slender elements) may be conservatively taken as shown in Fig. 2(C).

10.8.3 *Types of Elements*

a) *Internal elements* — These are elements attached along both longitudinal edges to other elements or to longitudinal stiffeners connected at suitable intervals to transverse stiffeners; for example, web of I-section and flanges and web of box section;

b) *Outside elements or outstands* — These are elements attached along only one of the longitudinal edges to an adjacent element, the other edge being free to displace out of plane, for example flange overhang of an I-section, stem of T-section and legs of an angle section; and

c) *Tapered elements* — These may be treated as flat elements having average thickness as defined in accepted standard [C-6A(36)].

The design of slender compression element (Class 4) considering the strength beyond elastic local buckling of element is outside the scope of this section. Reference may be made to in good practice [C-6A(35)] for such design provisions. The design of slender web elements may be made as given in **15.2.1.1** for flexure and **15.4.2.2** for shear.

10.8.4 *Compound Elements in Built-up Section* (*see* Fig. 2)

In case of compound elements consisting of two or more elements bolted or welded together, the limiting width to thickness ratios as in Table 2 should be considered on basis of the following:

a) Outstanding width of compound element (b_e) to its own thickness;

b) The internal width of each added plate between the lines of welds or fasteners connecting it to the original section to its own thickness; and

c) Any outstand of the added plates beyond the line of welds or fasteners connecting it to original section to its own thickness.

10.9 Maximum Effective Slenderness Ratio

The maximum effective slenderness ratio, KL/r, values of a beam, strut or tension member shall not exceed those given in Table 3. 'KL' is the effective length of the member and 'r' is appropriate radius of gyration based on the effective section as defined in **10.8**.

Table 2 Limiting Width to Thickness Ratio

(*Foreword* *and Clauses* 10.8.2(a), 10.8.2(b), 10.8.2(c), 10.8.2(d),10.8.4, 11.5.2.2, 14.3.1 *and* 15.6.3.1)

i)	Outstanding element	Under uniform compression		b/t_f	8.7ε	9.7ε	13.6ε (*a* in Fig. 2C)
		Non uniform stress	Tip in compression	b/t_f	$\frac{8.7\,\varepsilon}{r_1}$	$\frac{9.7\,\varepsilon}{r_1}$	$21\varepsilon\sqrt{k_\sigma}$
			Tip in tension	b/t_f	$\frac{8.7\,\varepsilon}{r_1\sqrt{r_1}}$	$\frac{9.7\,\varepsilon}{r_1\sqrt{r_1}}$	$21\varepsilon\sqrt{k_\sigma}$
ii)	Web of I, Channel, H, box or RHS	Axial compression		d/t_w	27ε	33 ε	37ε (*b* in Fig. 2C)
		Non uniform stress	Neutral axis at mid-depth	d/t_w	70ε	80ε	117ε
			$r_1 > 0.5$ (or) $r_2 > -1$	d/t_w	$\frac{122\,\varepsilon}{5.5\,r_1 - 1}$	$\frac{182\,\varepsilon}{6.53\,r_1 - 1}$	$\frac{37\,\varepsilon}{0.608 + 0.343\,r_2 + 0.049\,r_2^2}$
			$r_1 \le 0.5$ (or) $r_2 \le -1$	d/t_w	$\frac{35\,\varepsilon}{r_1}$	$\frac{40\,\varepsilon}{r_1}$	$59\,\varepsilon\,(1 - r_2)$
iii)	Angle, compression due to bending (Both criteria should be satisfied)			b/t d/t	8.7 ε 8.7 ε	9.7 ε 9.7 ε	14.5 ε 14.5 ε
iv)	Single angle, or double angles with the components separated, axial compression (All three criteria should be satisfied)			b/t d/t $(b+d)/t$	Not applicable		14.5 ε 14.5 ε 22.3 ε
v)	Outstanding leg of an angle in contact back-to-back in a double angle member or with another component			d/t	8.7ε	9.7ε	14.5 ε
vi)	Circular, elliptical hollow tube (*see* Note 6), including welded tube	a) bending moment		D_e/t	48 ε^2	68 ε^2	87 ε^2
		b) axial compression		D_e/t	Not applicable		87 ε^2

NOTES

1 Elements which exceed semi-compact limits are to be taken as of slender cross section

2 $\varepsilon = \sqrt{(250 / fy)}$

3 Webs shall be checked for shear buckling in accordance with **15.4.2** when $d/t > 67\varepsilon$. Where, *b* is the width of the element may be taken as clear distance between lateral supports or between lateral support and free edge, as appropriate, *t* is the thickness of element, *d* is the depth of the web, *D* is the outer diameter of the element (*see* Fig 2, **10.8.3** and **10.8.4**).

4 Different elements of a cross section can be in different classes. In such cases the section is classified based on the least favourable classification.

5 The stress ratio r_1 and r_2 are defined as:

$$r_1 = \frac{\text{depth under compression}}{\text{Overall depth}}$$

$$r_2 = \frac{\text{Minimum compressive stress (tensile if negative)}}{\text{Maximum design compressive stress of web alone}}$$

6 (a) for circular sections $D_e = D$,

(b) Elliptical sections: (h = major axis, b = minor axis)

in compression: $D_e = h\left[1 + \left(1 - 2.3\left(\frac{t}{h}\right)^{0.6}\right)\left(\frac{h}{b} - 1\right)\right]$

conservatively $D_e = \frac{h^2}{b}$

In bending about the strong (minor) axis

For h/b ≤ 1.36: $D_e = \frac{b^2}{h}$

For h/b > 1.36: $D_e = 0.4\,\frac{h^2}{b}$

In compression and or bending about weak axis:

$D_e = \frac{h^2}{b}$

7 k_σ is the buckling factor given by:

Maximum compression at free edge	r_2	1	0	–1	–1 to – 3
	K_σ	0.43	0.57	0.85	$0.57 - 0.21k_2 + 0.07r_2$
Maximum Compression at supported edge	r_2	1	$0 < r_2 < 1$	0	$-1 < r_2 < 0$
	K_σ	0.43	$0.578/(r_2 + 0.34)$	1.70	$1.7 - 5\,r_2 + 17.1\,r_2^2$

Fig. 2(C) Effective Section of Slender Elements

Fig.2 Classification of Sections

Table 3 Maximum Values of Effective Slenderness Ratios

(*Clause* 10.9)

Sl No. (1)	**Member** (2)	**Maximum Effective Slenderness Ratio *KL/r*** (3)
i)	A member carrying compressive loads resulting from dead loads and imposed loads	180
ii)	A tension member in which a reversal of direct stress occurs due to loads other than wind or seismic forces	180
iii)	A member subjected to compression forces resulting only from combination with wind/earthquake effects, provided the deformation of such member does not adversely affect the stress in any part of the structure	250
iv)	Compression flange of a beam against lateral torsional buckling	300
v)	A member normally acting as a tie in a roof truss or a bracing system not considered effective when subject to possible reversal of stress into compression resulting from the action of wind or earthquake effects[1)]	350
vi)	Members always under tension[1)] (other than pre-tensioned members)	400

[1)] Tension members, such as bracings, where sag is avoided, need not satisfy the maximum slenderness ratio limits.

10.10 Resistance to Horizontal Forces

10.10.1 In designing the steel frame work of a building, provision shall be made (by adequate moment connections or by a system of bracing) to effectively transmit to the foundations all the horizontal forces, giving due allowance for the stiffening effect of the walls and floors, where applicable.

10.10.2 When the walls, or walls and floors and/or roofs are capable of effectively transmitting all the horizontal forces directly to the foundations, the structural steel framework may be designed without considering the effects of wind or earthquake.

10.10.3 Wind and earthquake effects are reversible and therefore call for initial stiffness and strength under force reversal in both longitudinal and transverse directions. To resist torsional effects of wind and earthquake forces, bracings in plan should be provided and integrally connected with the longitudinal and transverse bracings, to impart adequate torsional resistance to the structure.

10.10.3.1 In shed type steel mill buildings, adequate bracings shall be provided to transfer the wind or earthquake loads from their points of action to the appropriate supporting members. Where the connections to the interior columns or frames are designed such that the wind or earthquake loads will not be transferred to the interior columns, the exterior columns or frames shall be designed to resist the total wind or earthquake loads. Where the connections to the interior columns and frames are designed such that the wind or earthquake effects are transferred to the interior columns also, and where adequate rigid diaphragm action can be mobilized as in the case of the cast-in place RC slab, both exterior and interior columns and frames may be designed on the assumption that the wind or earthquake load is divided among them in proportion to their relative stiffness. Columns also should be designed to withstand the net uplifting effect caused by excessive wind or earthquake shaking. Additional axial forces arising in adjacent columns due to the vertical component of bracings or due to frame action shall also be accounted for.

10.10.3.2 Earthquake forces are proportional to the seismic mass as defined in 5 of Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS. Earthquake forces should be applied at the centre of mass of all such components and their transfer to the foundation should be ensured. Other construction details, stipulated in good practice [C-6A(37)] should also be followed.

10.10.3.3 In buildings where high-speed traveling cranes are supported or where a building or structure is otherwise subjected to vibration or sway, triangulated bracing or rigid portal systems shall be provided to reduce the vibration or sway to an acceptable minimum.

10.10.4 *Foundations*

The foundations of a building or other structures shall be designed to provide the rigidity and strength that has been assumed in the analysis and design of the superstructure.

10.10.5 *Eccentrically Placed Loads*

Where a wall, or other gravity load, is placed eccentrically upon the flange of a supporting steel beam, the beam and its connections shall be designed for torsion, unless the beam is restrained laterally in such a way as to prevent the twisting of the beam.

10.11 Expansion Joints

Expansion joints in case of low-rise buildings (up to three storeys) shall comply with **10.11.1** to **10.11.4**. For requirement of expansion joints in high-rise buildings, specialist literature shall be referred to.

10.11.1 In view of the large number of factors involved in deciding the location, spacing and nature of expansion joints, the decision regarding provision of expansion joints shall be left to the discretion of the designer.

10.11.2 Structures in which marked changes in plan dimensions take place abruptly, shall be provided with expansion joints at the section where such changes occur. Expansion joints shall be so provided that the necessary movement occurs with minimum resistance at the joint. The gap at the expansion joint should be such that:

a) it accommodates the expected expansion/contraction due to seasonal and diurnal variation of temperature; and

b) it avoids pounding of adjacent units under earthquake shaking. The structure adjacent to the joint should preferably be supported on separate columns but not necessarily on separate foundations.

10.11.3 The details as to the length of a structure where expansion joints have to be provided may be determined after taking into consideration various factors such as temperature, exposure to weather and structural design. The provisions in **10.11.3.1** to **10.11.3.3** are given as general guidance. The provision for expansion may be made by providing double framing at the joint or providing for expansion at the connection to the single framing in detailing.

10.11.3.1 If one bay of longitudinal bracing is provided at the centre of the building or building section, the length of the building section may be restricted to 180 m in case of covered buildings and 120 m in case of open gantries (*see* Fig. 3).

10.11.3.2 If more than one bay of longitudinal bracing is provided near the centre of the building/section, the maximum centre line distance between the two lines of bracing may be restricted to 50 m for covered buildings (and 30 m for open gantries) and the maximum distance between the centre of the bracing to the nearest expansion joint/end of building or section may be restricted to 90 m (60 m in case of open gantries). The maximum length of the building section thus may be restricted to 230 m for covered buildings (150 m for open gantries). Beyond this, suitable expansion joints shall be provided (*see* Fig.4).

10.11.3.3 The maximum width of the covered building section should preferably be restricted to 150 m beyond which suitable provisions for the expansion joint may be made.

10.11.4 When the provisions of these sections are met for a building or open structure made only of steel frame with elastic steel claddings, the stress analysis due to temperature is not required. However, for buildings, specialist literature may be referred to decide on thermal stress design.

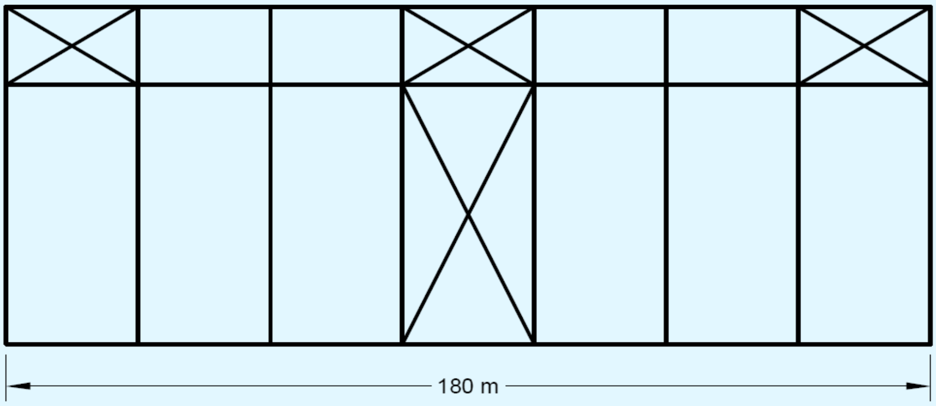

FIG. 3 MAXIMUM LENGTH OF BUILDING WITH ONE BAY OF BRACING

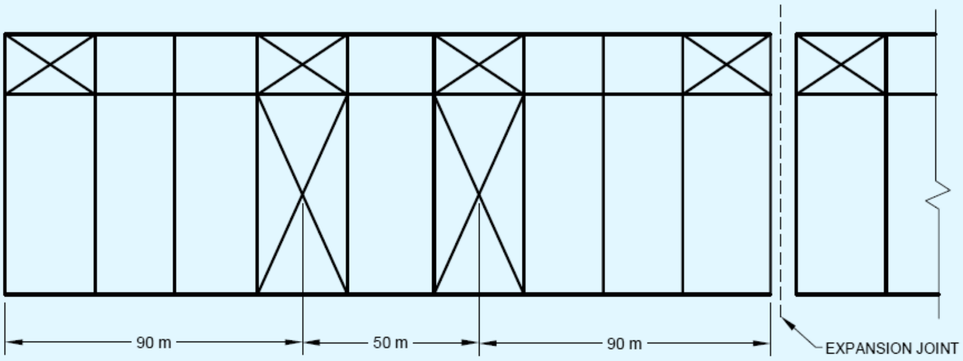

FIG. 4 MAXIMUM LENGTH OF COVERED BUILDING/SECTION WITH TWO BAYS OF BRACINGS

11 METHODS OF STRUCTURAL ANALYSIS

11.1 Methods of Determining Action Effects

11.1.1 *General*

For the purpose of complying with the requirements of the limit states of stability, strength and serviceability specified under Section **12** on the effects of design actions on a structure and its members and connections, shall be determined by structural analysis using the assumptions of **11.2** and **11.3** and one of the following methods of analysis:

a) elastic analysis in accordance with **11.4**;

b) plastic analysis in accordance with **11.5**;

c) advanced analysis in accordance with Annex B; or

d) dynamic analysis in accordance with **5** of Part C 'Structural Design/Section 1 Loads and Load Effects' of this NBCS.

The effects of design earthquake shaking specified in Section **18** shall be estimated by elastic analysis. Plastic analysis shall not be employed to obtain member forces corresponding to design earthquake shaking specified in Section **18**. More information on analysis to resist earthquake effects is given in **5** of Part C 'Structural Design/ Section 1 Loads and Load Effects' of this NBCS.

11.1.2 *Non-sway and Sway Frames*

For the purpose of analysis and design, the structural frames are classified as non-sway and sway frames as given below:

a) *Non-sway frame* — One in which the transverse displacement of one end of the member relative to the other end is effectively prevented. This applies to triangulated frames and trusses or to frames where in-plane stiffness is provided by bracings, or by shear walls, or by floor slabs and roof decks secured horizontally to walls or to bracing systems parallel to the plane of loading and bending of the frame;

b) *Sway frame* — One in which the transverse displacement of one end of the member relative to the other end is not effectively prevented. Such members and frames occur in structures which depend on flexural action of members to resist lateral loads and sway, as in moment resisting frames; and

c) A rigid jointed multi-storey frame may be considered as a non-sway frame if in every individual storey, the deflection δ, over a storey height h_s, due to the notional horizontal loading given in **11.3.6** satisfies the following criteria:

   1) For clad frames, when the stiffening effect of the cladding is not taken into account in the deflection calculations:

$$\delta \leq \frac{h_s}{2\,000}$$

   2) For unclad frame or clad frames, when the stiffening effect of the cladding is taken into account in the deflection calculations:

$$\delta \leq \frac{h_s}{4\,000}$$

   3) A frame, which when analyzed considering all the lateral supporting system does not comply with the above criteria, should be classified as a sway frame, even if it is braced or otherwise laterally stiffened.

11.2 Forms of Construction Assumed for Structural Analysis

11.2.1 The effects of design action in the members and connections of a structure shall be determined by assuming singly or in combination of the following forms of construction (*see* **17.6.1**).

11.2.1.1 *Rigid construction*

In rigid construction, the connections between members (beam and column) at their junction shall be assumed to have sufficient rigidity to hold the original angles between the members connected at a joint unchanged under loading.

11.2.1.2 *Semi-rigid construction*

In semi-rigid construction, the connections between members (beam and column) at their junction may not have sufficient rigidity to hold the original angles between the members at a joint unchanged, but shall be assumed to have the capacity to furnish a dependable and known degree of flexural restraint. The relationship between the degree of flexural restraint and the level of the load effects shall be established by any rational method or based on test results (*see* Annex F).

11.2.1.3 *Simple construction*

In simple construction, the connections between members (beam and column) at their junction will not resist any appreciable moment and shall be assumed to be hinged.

11.2.2 *Design of connections*

The design of all connections shall be consistent with the form of construction, and the behaviour of the connections shall not adversely affect any other part of the structure beyond what is allowed for in design. Connections shall be designed in accordance with provisions under **17**.

11.3 Assumptions in Analysis

11.3.1 The structure shall be analyzed in its entirety except as follows:

a) Regular building structures, with orthogonal frames in plan, may be analyzed as a series of parallel two-dimensional sub-structures (part of a structure), the analysis being carried out in each of the two directions, at right angles to each other, except when there is significant load redistribution between the sub-structures (part of a structure);

b) For vertical loading in a multi-storey building structure, provided with bracing or shear walls to resist all lateral forces, each level thereof, together with the columns immediately above and below, may be considered as a substructure, the columns being assumed fixed at the ends remote from the level under consideration; and

c) Where beams at a floor level in a multi-bay building structure are considered as a substructure (part of a structure), the bending moment at the support of the beam due to gravity loads may be determined based on the assumption that the beam is fixed at the far end support, one span away from the span under consideration, provided that the floor beam is continuous beyond that support point.

11.3.2 *Span Length*

The span length of a flexural member in a continuous frame system shall be taken as the centre-to-centre distance between the supports.

11.3.3 *Arrangements of Imposed Loads in Buildings*

For building structures, the various arrangements of imposed loads considered for the analysis, shall include at least the following:

a) Where the loading pattern is fixed, the arrangement concerned;

b) Where the imposed load is variable and not greater than three-quarters of the dead load, the imposed load may be taken to be acting on all spans; and

c) Where the imposed load is variable and exceeds three-quarters of the dead load, arrangements of imposed load acting on the floor under consideration shall include the following cases:

    1) imposed load on alternate spans;

    2) imposed load on two adjacent spans; and

    3) imposed load on all the spans.

11.3.4 *Base Stiffness*

In the analysis of all structures, the appropriate base stiffness about the axis under consideration shall be used. In the absence of the knowledge of the pedestal and foundation stiffness, the following may be assumed:

a) When the column is rigidly connected to a suitable foundation, the stiffness of the pedestal shall be taken as the stiffness of the column above base plate. However, in case of very stiff pedestals and foundations the column may be assumed as fixed at base;

b) When the column is nominally connected to the foundation, a pedestal stiffness of 10 percent of the column stiffness may be assumed;

c) When an actual pin or rocker is provided in the connection between the steel column and pedestal, the column is assumed as hinged at base and the pedestal and foundation may be appropriately designed for the reactions from the column; and

d) In case of (a) and (b), the bottom of the pedestal shall be assumed to have the following boundary condition in the absence of any detailed procedure based on theory or tests:

    1) When the foundation consists of a group of piles with a pile cap, raft foundation or an isolated footing resting on rock or very hard soil, the pedestal shall be assumed to be fixed at the level of the bottom of footing or at the top of the pile cap. Pedestal to be considered as fixed at top of pile cap, where

the Single Piles are tied at Pile cap level by means of ground beams (in both orthogonal directions) with required stiffness;

2) When the foundation consists of an isolated footing resting on other soils, the pedestal shall be assumed to be hinged at the level of the bottom of the footing;

3) When the pedestal is supported by a single pile, which is laterally surrounded by soil providing passive resistance, the pile shall be assumed to be fixed at a depth of 5 times the diameter of the pile below the ground level in case of compact ground or the top level of compact soil in case of poor soil overlying compact soil. Single pile cap, connected flexurally to orthogonal beams having adequate stiffness, shall be assumed to be fixed at the top of pile cap; and

4) When the column is founded into rock, it may be assumed to be fixed at the interface of the column and rock.

11.3.5 *Simple Construction*

Bending members may be assumed to have their ends connected for shear only and to be free to rotate. In triangulated structures, axial forces may be determined by assuming that all members are pin-connected. The eccentricity for stanchion and column shall be assumed in accordance with **14.3.3**.

11.3.6 *Notional Horizontal Loads*

To analyze a frame subjected to gravity loads, considering the sway stability of the frame, notional horizontal forces should be applied. These notional horizontal forces account for practical imperfections and should be taken at each level as being equal to 0.5 percent of factored dead load plus vertical imposed loads applied at that level. The notional load should not be applied along with other lateral loads, such as wind and earthquake effects, in the analysis.

11.3.6.1 The notional forces should be applied on the whole structure, in both orthogonal directions, in one direction at a time, at roof and all floor levels or their equivalent. They should be taken as acting simultaneously with factored gravity loads.

11.3.6.2 The notional force should not be:

a) applied when considering overturning or overall instability;

b) combined with other horizontal (lateral) loads;

c) combined with temperature effects; and

d) taken to contribute to the net shear on the foundation.

11.3.6.3 The sway effect using notional load under gantry load case need not be considered if the ratio of height to lateral width of the building is less than unity.

11.4 Elastic Analysis

11.4.1 *Assumptions*

Individual members shall be assumed to remain elastic under the action of the factored design loads for all limit states.

The effect of haunching or any variation of the cross section along the axis of a member shall be considered, and where significant, shall be taken into account in the determination of the member stiffness.

11.4.2 *First-order Elastic Analysis*

In a first-order elastic analysis, the equilibrium of the frame in the undeformed geometry is considered, the changes in the geometry of the frame due to the loading are not accounted for, and changes in the effective stiffness of the members due to axial force are neglected. The conditions under which the first order elastic analysis results are adequate for design are given in Section **11.7**.

11.5 Plastic Analysis

11.5.1 *Application*

The effects of design action throughout or on part of a structure may be determined by a plastic analysis, provided that the requirements of **11.5.2** are met. The distribution of design action effects shall satisfy equilibrium and the boundary conditions.

11.5.2 *Requirements*

When a plastic method of analysis is used, all of the following conditions shall be satisfied, unless adequate ductility of the structure and plastic rotation capacity of its members and connections are established for the design loading conditions by other means of evaluation:

a) The yield stress of the grade of the steel used shall not exceed 450 MPa;

b) The stress-strain characteristics of the steel shall not be significantly different from those obtained for steels complying with the accepted standard [C-6A(6)] or equivalent and shall be such as to ensure complete plastic moment redistribution. The stress-strain diagram shall have a plateau at the yield stress, extending for at least six times the yield strain. The ratio of the tensile strength to the yield stress specified for the grade of the steel shall not be less than 1.2. The elongation on a gauge length complying with the accepted standard [C-6A(6)] shall not be less than 15 percent; and the steel shall exhibit strain-hardening capability. Steels conforming to the accepted standard [C-6A(6)] shall be deemed to satisfy the above requirements;

c) The members used shall be hot-rolled or fabricated using hot-rolled plates and sections;

d) The cross section of members not containing plastic hinges should be at least that of compact section (*see* **10.8.2**), unless the members meet the strength requirements from elastic analysis;

e) Where plastic hinges occur in a member, the proportions of its cross section should not exceed the limiting values for plastic section given in **10.8.2**;

f) The cross section should be symmetrical about its axis perpendicular to the axis of the plastic hinge rotation; and

g) The members shall not be subject to impact loading, requiring fracture assessment or fluctuating loading, requiring a fatigue assessment [*see* **19**].

11.5.2.1 *Restraints*

If practicable, torsional restraint (against lateral buckling) should be provided at all plastic hinge locations. Where not feasible, the restraint should be provided within a distance of $D/2$ of the plastic hinge location, where D is the total depth of section.

The torsional restraint requirement at a section as above, need not be met at the last plastic hinge to form, provided it can be clearly identified.

Within a member containing a plastic hinge, the maximum distance L_m from the restraint at the plastic hinge to an adjacent restraint should be calculated by any rational method or the conservative method given below, so as to prevent lateral buckling.

Conservatively L_m (in mm) may be taken as:

$$L_\mathrm{m} \le \frac{38 r_\mathrm{y}}{\left[\dfrac{f_\mathrm{c}}{130} + \left(\dfrac{f_\mathrm{y}}{250}\right)^2 \left(\dfrac{x_\mathrm{t}}{40}\right)^2\right]^{1/2}}$$

where

A = area of cross section;

f_c = actual, in N/mm^2, compressive stress on the cross section due to axial load;

f_y = yield, in N/mm^2, stress;

I_w, I_y, I_t = warping constant, second moment of the cross section about the minor axes and St. Venant's torsion constant, respectively;

r_y = radius, in mm, of gyration about the minor axis; and

x_t = torsional index, $x_t = 1.132(AI_w / I_y I_t)^{0.5}$.

Where the member has unequal flanges, r_y should be taken as the lesser of the values of the compression flange only or the whole section.

Where the cross section of the member varies within the length L_m, the maximum value of r_y and the minimum value of x_t should be used.

The spacing of restraints to member lengths not containing a plastic hinge should satisfy the recommendations of section on lateral buckling strength of beams (*see* **15.2.2**). Where the restraints are placed at the limiting distance L_m, no further checks are required.

11.5.2.2 *Stiffeners at plastic hinge locations*

Web stiffeners should be provided where a concentrated load, which exceeds 10 percent of the shear capacity of the member, is applied within *D/2* of a plastic hinge location, (*see* **15.2.1.2**). The stiffener should be provided within a distance of half the depth of the member on either side of the hinge location and be designed to carry the applied load in accordance with **15.7.4**. If the stiffeners are flat plates, the outstand width to the thickness ratio, *b*/*t*, should not exceed the values given in the plastic section (*see* **10.7** and Table 2). Where other sections are used, the ratio $\left(\frac{I_{so}}{I_t}\right)^{1/2}$, should not exceed the values given for plastic section (for simple outstand, as in **10.7**);

where

I_{so} = second moment of area of the stiffener about the face of the element perpendicular to the web; and

I_t = St. Venant's torsion constant of the stiffener.

11.5.2.3 The frame shall be adequately supported against sway and out-of-plane buckling, by bracings, moment resisting frame or an independent system such as shear wall.

11.5.2.4 *Fabrication restriction*

Within a length equal to the member depth, on either side of a plastic hinge location, the following restrictions should be applied to the tension flange and noted in the design drawings. Holes, if required, should be drilled or else punched 2 mm undersize and reamed. All sheared or hand flame cut edges should be finished smooth by grinding, chipping or planning.

11.5.3 *Assumptions in Analysis*

The design action effects shall be determined using a rigid-plastic analysis.

It shall be permissible to assume full strength or partial strength connections, provided the capacities of these are used in the analysis, and provided that:

a) In a full strength connection, the moment capacity of the connection shall be not less than that of the member being connected;

b) In a partial strength connection, the moment capacity of the connection may be less than that of the member being connected; and

c) In both cases the behavior of the connection shall be such as to allow all plastic hinges necessary for the collapse mechanism to develop, and shall be such that the required plastic hinge rotation does not exceed the rotation capacity at any of the plastic hinges in the collapse mechanism.

In the case of building structures, it is not normally necessary to consider the effect of alternating plasticity.

11.6 Frame Buckling Analysis

11.6.1 The elastic buckling load factor (λ_{cr}) shall be the ratio of the elastic buckling load set of the frame to the design load set for the frame, and shall be determined in accordance with **11.6.2**.

NOTE — The value of λ_{cr} depends on the load set and has to be evaluated for each possible set of load combination.

11.6.2 *In-plane frame buckling*

The elastic buckling load factor (λ_{cr}) of a rigid-jointed frame shall be determined by using:

a) One of the approximate methods of **11.6.2.1** and **11.6.2.2**; or

b) A rational elastic buckling analysis of the whole frame.

11.6.2.1 *Regular non-sway frames* (*see* **11.1.2**)

In a rectangular non-sway frame with regular loading and negligible axial forces in the beams, the Euler buckling stress $f_{cr,}$ for each column shall be determined in accordance with **14.1.2.1**. The elastic buckling load factor (λ_{cr}) for the whole frame shall be taken as the lowest of the ratio of (f_{cr}/f_{cd}) for all the columns, where f_{cd} is the axial compressive stress in the column from the factored load analysis.

11.6.2.2 *Regular sway frames*

In a rectangular sway frame with regular loading and negligible axial forces in the beams, the buckling load, P_{cr}, for each column shall be determined as $P_{cr} = A\, f_{cr}$, where f_{cr} is the elastic buckling stress of the column in the plane of frame, obtained in accordance with **14.1.2.1**. The elastic buckling load factor $\lambda_{cr,}$ for the whole frame shall be taken as the lowest of all the ratios, λ_{scr}, calculated for each storey of the building, as given below:

$$\lambda_{scr} = \frac{\sum (P_{cr}/L)}{\sum (P/L)}$$

where

L = column length and the summation includes all columns in the plane frame within a storey; and

P = member axial force from the factored load analysis, with tension taken as negative.

11.7 Consideration of Second Order Effects

11.7.1 Any second-order effects of the loads acting on the structure in its deformed configuration may be neglected and first order elastic analysis or plastic analysis results may be used provided the following are satisfied:

a) for clad frames, provided with the stiffening effects of masonry infill wall panels or diaphragms of profiled wall panel is not taken into account, and where elastic buckling load factor, λ_{cr} (*see* **11.6**) satisfies $\lambda_{cr}/\lambda_P \geq 10$;

If $10 > \lambda_{cr}/\lambda_P \geq 4.6$ the second-order effects may be considered by amplifying the design load effects obtained from elastic/plastic analysis by a factor as given in **11.7.3.1**.

If $\lambda_{cr}/\lambda_P < 4.6$, second-order elastic analysis or second-order plastic analysis (*see* **11.7.3**) is to be carried out.

b) for un-clad frames or for clad frames where the stiffening effects of masonry infill or diaphragms of profiled wall panel is taken into account, where elastic buckling load factor, λcr (see 11.6) satisfies $\lambda cr / \lambda_P \geq 20$.

If $20 > \lambda_{cr} / \lambda_P \geq 5.75$ the second-order effects may be considered by amplifying the design load effects obtained from plastic analysis by a factor as given in **11.7.3.2**.

If $\lambda_{cr}/\lambda_P < 5.75$, second-order elasto-plastic analysis or second-order elastic analysis (*see* **11.7.2**) shall be carried out.

where

λ_p = Ultimate load factor from elastic or plastic analysis.

11.7.2 *Second-order Elastic Analysis*

11.7.2.1 The analysis shall allow for the effects of the design loads acting on the structure and its members in their displaced and deformed configuration. These second-order effects shall be taken into account by using either:

a) a first-order elastic analysis with moment amplification in accordance with **11.7.3.1**, **11.7.3.2**, provided the moment amplification factors, K_y and K_z are not greater than 1.4; or

b) a second-order elastic analysis in accordance with Annex B.

11.7.3 Moment Amplification

11.7.3.1 *Moment amplification for members in non-sway frames*

For a member with zero axial compression or a member subject to axial tension, the design bending moment is that obtained from the first-order analysis for factored loads, without any amplification.

For a braced member with a design axial compressive force P_d as determined by the first-order analysis, the design bending moment shall be calculated considering moment amplification as in **16.3.2.2**.

11.7.3.2 *Moment amplification for members in sway frames*

The design bending moment shall be calculated as the product of moment amplification factor, [*see* **16.3.2.2** (K_y, K_z)] and the moment obtained from the first-order analysis of the sway frame, unless analysis considering second order effects is carried out (*see* **11.7.2**).

11.7.4 The calculated bending moments from the first order elastic analysis may be modified by redistribution up to 15 percent of the peak calculated moment of the member under factored load, provided that:

a) in which the moments are reduced shall belong to plastic or compact section classification (*see* **10.8**). the internal forces and moments in the members of the frame are in equilibrium with applied loads; and

b) all the members.

12 LIMIT STATE DESIGN

12.1 Basis for Design

12.1.1 In the limit state design method, the structure shall be designed to withstand safely all loads likely to act on it throughout its life. It shall not suffer total collapse under accidental loads such as from explosions or impact or due to consequences of human error to an extent beyond the local damages. The objective of the design is to achieve a structure that will remain fit for use during its life with acceptable target reliability. In other words, the probability of a limit state being reached during its lifetime should be very low. The acceptable limit for the safety and serviceability requirements before failure occurs is called a limit state. In general, the structure shall be designed on the basis of the most critical limit state and shall be checked for other limit states.

12.1.2 Steel structures are to be designed and constructed to satisfy the design requirements with regard to stability, strength, serviceability, brittle fracture, fatigue, fire, and durability such that they meet the following:

a) Remain fit with adequate reliability and be able to sustain all actions (loads) and other influences experienced during construction and use;

b) Have adequate durability under normal maintenance; and

c) Do not suffer overall damage or collapse disproportionately under accidental events like explosions, vehicle impact or due to consequences of human error to an extent beyond local damage. The potential for catastrophic damage shall be limited or avoided by appropriate choice of one or more of the following:

   1) Avoiding, eliminating or reducing exposure to hazards, which the structure is likely to sustain;

   2) Choosing structural forms, layouts and details and designing such that;

      i) the structure has low sensitivity to hazardous conditions; and

      ii) the structure survives with only local damage even after serious damage to any one individual element by the hazard.

   3) Choosing suitable material, design and detailing procedure, construction specifications, and control procedures for shop fabrication and field construction as relevant to the particular structure.

12.1.3 The following conditions may be satisfied to avoid a disproportionate collapse:

a) The building should be effectively tied together at each principal floor level and each column should be effectively held in position by means of continuous ties (beams) nearly orthogonal, except where the steel work supports only cladding weighing not more than 0.7 kN/m^2 along with imposed and wind loads. These ties must be steel members such as beams, which may be designed for other purposes, steel bar reinforcement anchoring the steel frame to concrete floor or steel mesh reinforcement in composite slab with steel profiled sheeting directly connected to beam with shear connectors. These steel ties and their end connections should be capable of resisting factored tensile force not less than the factored dead and imposed loads acting on the floor area tributary to the tie nor less than 75 kN. Such connection of ties to edge column should also be capable of resisting 1 percent of the maximum axial compression in the column at the level due to factored dead and imposed loads. All column splices should be capable of resisting a tensile force equal to the largest of a factored dead and imposed load reaction from a single floor level located between that column splice and the next column splice below that splice. Lateral load system to resist notional horizontal loads prescribed in **11.3.6** should be distributed throughout the building in nearly orthogonal directions so that no substantial portions is connected at only one point to such a system. Precast concrete or other heavy floor or roof units should be effectively anchored in the direction of their span either to each other over the support or directly to the support.

b) Where the above conditions to tie the columns to the floor adequately are not satisfied each storey of the building should be checked to ensure that disproportionate collapse would not precipitate by the notional removal, one at a time, of each column.

c) Where each floor is not laterally supported by more than one system, check should be made at each storey by removing one such lateral support system at a time to ensure that disproportionate collapse would not occur. The collapse is considered disproportionate, if more than 15 percent of the floor or roof area of 70 m^2 collapse at that level and at one adjoining level either above or below it, under a load equal to 1.05 or 0.9 times the dead load, 0.33 times temporary or full imposed load of permanent nature (as in storage buildings) and 0.33 times wind load acting together.

12.1.4 Structures designed for unusual or special functions shall comply with any other relevant additional limit state considered appropriate to that structure.

12.2 Limit State Design

12.2.1 For achieving the design objectives, the design shall be based on characteristic values for material strengths and applied loads (actions), which take into account the probability of variations in the material strengths and in the loads to be supported. The characteristic values shall be based on statistical data, if available. Where such data is not available, these shall be based on experience. The design values are derived from the characteristic values through the use of partial safety factors, both for material strengths and for loads. In the absence of special considerations, these factors shall have the values given in this Section according to the material, the type of load and the limit state being considered. The reliability of design is ensured by satisfying the requirement:

$$\text{Design action} \leq \text{Design strength}$$

12.2.2 Limit states are the states beyond which the structure no longer satisfies the performance requirements specified. The limit states are classified as:

a) limit state of strength; and

b) limit state of serviceability.

12.2.2.1 The limit states of strength are those associated with failures (or imminent failure), under the action of probable and most unfavourable combination of loads on the structure using the appropriate partial safety factors, which may endanger the safety of life and property. The limit state of strength includes:

a) loss of equilibrium of the structure as a whole or any of its parts or components;

b) loss of stability of the structure (including the effect of sway where appropriate and overturning) or any of its parts including supports and foundations;

c) failure by excessive deformation, rupture of the structure or any of its parts or components;

d) fracture due to fatigue; and

e) brittle fracture.

12.2.2.2 The limit state of serviceability include:

a) deformation and deflections, which may adversely affect the appearance or effective use of the structure or may cause improper functioning of equipment or services or may cause damages to finishes and non-structural members;

b) vibrations in the structure or any of its components causing discomfort to people, damages to the structure, its contents or which may limit its functional effectiveness. Special consideration shall be given to systems susceptible to vibration, such as large open floor areas free of partitions to ensure that such vibrations are acceptable for the intended use and occupancy (*see* Annex C).;

c) repairable damage or crack due to fatigue;

d) corrosion, durability; and

e) fire.

12.3 Actions

The actions (loads) to be considered in design include direct actions (loads) experienced by the structure due to self-weight, external actions, etc, and imposed deformations such as that due to temperature and settlements.

12.3.1 *Classification of Actions*

Actions are classified by their variation with time as given below:

a) *Permanent actions* (Q_p) — Actions due to self-weight of structural and non-structural components, fittings, ancillaries, and fixed equipment, etc;

b) *Variable actions* (Q_v) — Actions due to construction and service stage loads such as imposed (live) loads (crane loads, snow loads, etc), wind loads, and earthquake effects; and

c) *Accidental actions* (Q_a) — Actions expected due to explosions, and impact of vehicles, etc.

12.3.2 *Characteristic Actions* (*Loads*)

12.3.2.1 The characteristic actions, Q_c, are the values of the different actions that are not expected to be exceeded with more than 5 percent probability, during the life of the structure and they are taken as:

a) the self-weight, in most cases calculated on the basis of nominal dimensions and unit weights [*see* **2** of Part C ‘Structural Design/Section 1 Loads and Load Effects’ of this NBCS];

b) the variable loads, values of which are specified in relevant standard [(*see* Part C ‘Structural design/Section 1 Loads and Load Effects’ of this NBCS];

c) the upper limit with a specified probability (usually 5 percent) not exceeding during some reference period (design life); and

d) specified by client, or by designer in consultation with client, provided they satisfy the minimum provisions of the relevant loading standard.

12.3.2.2 The characteristic values of accidental loads generally correspond to the value specified by relevant code, standard or client. The design for accidental load is generally not required in building unless it is required by client or approving authority in which case, generally recommendation in **12.1.2 (c)** or specialist literature shall be followed.

12.3.3 *Design Actions*

The design action, Q_{d}, is expressed as:

$$Q_d = \sum_k \gamma_{\mathrm{Lk}} Q_{\mathrm{ck}}$$

where

$_{\mathrm{Lk}}$ = partial safety factor for different loads k, given in Table 4 to account for.

1) possibility of unfavourable deviation of the load from the characteristic value;

2) possibility of inaccurate assessment of the load;

3) uncertainty in the assessment of effects of the load; and

4) uncertainty in the assessment of the limit states being considered.

The loads, Load combinations and the relevant partial safety factors for loads in a combination shall be as given in Part C/Section 1 of this NBCS. The loads or load effects shall be multiplied by the relevant γ_{L} factors, given in Table 4, to get the design loads or design load effects, when such a value is not available in Part C/Section 1 of this NBCS.

12.4 Strength

The ultimate strength calculation may require consideration of the following:

a) Loss of equilibrium of the structure or any part of it, considered as a rigid body; and

b) Failure by excessive deformation, rupture or loss of stability of the structure or any part of it including support and foundation.

12.4.1 *Design Strength*

The design strength, S_{d}, is obtained as given below from ultimate strength, S_{u} and partial safety factors for materials, γ_{m} given in Table 5.

$$S_{\mathrm{d}} = S_{\mathrm{u}} / \gamma_{\mathrm{m}}$$

where partial safety factor for materials, γ_{m} account for:

a) possibility of unfavourable deviation of material strength from the characteristic value;

b) possibility of unfavourable variation of member sizes;

c) possibility of unfavourable reduction in member strength due to fabrication and tolerances; and

d) uncertainty in the calculation of strength of the members.

Table 4 Partial Safety Factors for Loads, γ_L, for Limit States

viii)	DL + IL + AL	1.0	0.35 4)	0.35 4)	—		1.0	—	—	—	—

Abbreviations:

DL= Dead load, IL= Imposed load, WL= Wind load, CL= Crane load (Vertical/Horizontal), AL=Accidental load, ER= Erection load, EL= Earthquake effects, FL = Forces due to restraints during fire.

NOTE — The effects of actions (loads) in terms of stresses or stress resultants may be obtained from an appropriate method of analysis as in **11**.

---

1) When action of different imposed loads is simultaneously considered, the leading imposed load shall be considered to be the one causing the higher load effects in the member/section.

2) This value is to be considered when the dead load contributes to stability against overturning is critical or the dead load causes reduction in stress due to other loads.

3) Imposed load shall be taken as the full characteristic specified values in case of storage loads and 50 percent of the specified characteristic values in other cases.

4) 0.35 shall not be used when the imposed load is not permeant load as in earth pressure.

12.5 Factors Governing the Ultimate Strength

12.5.1 *Stability*

Stability shall be ensured for the structure as a whole and for each of its elements. This should include, overall frame stability against overturning and sway, as given in **12.5.1.1** and **12.5.1.2**.

12.5.1.1 *Stability against overturning*

The structure as a whole or any part of it shall be designed to prevent instability due to overturning, uplift or sliding under factored load as given below:

a) The actions shall be divided into components aiding instability and components resisting instability;

b) The permanent and variable actions and their effects causing instability shall be combined using appropriate partial safety factors for loads as per the limit state requirements, to obtain maximum destabilizing effect;

c) The permanent actions (loads) and effects contributing to resistance shall be multiplied with a partial safety factor 0.9 and added together with design resistance (after multiplying with appropriate partial safety factor). Variable actions and their effects contributing to resistance shall be disregarded; and

d) The resistance effect shall be greater than or equal to the destabilizing effect. Combination of imposed and dead loads should be such as to cause most severe effect on overall stability.

12.5.1.2 *Sway stability*

The whole structure, including portions between expansion joints, shall be adequately stiff against sway. To ensure this, in addition to designing for applied horizontal loads, a separate check should be carried out for notional horizontal loads such as given in **11.3.6** to evaluate the sway under gravity loads.

12.5.2 *Fatigue*

Generally, fatigue need not be considered unless a structure or element is subjected to numerous significant fluctuations of stress. Stress changes due to fluctuations in wind loading normally need not be considered. Fatigue design shall be in accordance with the provisions under **19**. When designing for fatigue, the partial safety factor for load, γ_L, equal to unity shall be used for the load causing stress fluctuation and stress range.

12.5.3 *Plastic Collapse*

Plastic analysis and design may be used, if the requirement specified under the plastic method of analysis (*see* **11.5**) are satisfied.

12.6 Limit State of Serviceability

Serviceability limit state is related to the criteria governing normal use. Serviceability limit state is limit state beyond which the service criteria specified below, are no longer met:

a) deflection limit;

b) vibration limit;

c) durability consideration; and

d) fire resistance.

Unless specified otherwise (*see* Table 4), partial safety factor for loads, γ_L, of value equal to unity shall be used for all loads leading to serviceability limit states to check the adequacy of the structure under serviceability limit states.

12.6.1 *Deflection*

The deflection under serviceability loads of a building or a building component should not impair the strength of the structure or components or cause damage to finishing. Deflections are to be checked for the most adverse but realistic combination of service loads and their arrangement, by elastic analysis, using partial safety factors in Table 4 for loads, as required, in Table 6. Table 6 gives recommended limits of deflections for certain structural members and systems. In Table 6, imposed load should include all post construction loads including superimposed dead loads. Circumstances may arise where greater or lesser values would be more appropriate, depending upon the nature of material in element to be supported (vulnerable to cracking or not) and intended use of the structure, as required by client.

Where the deflection due to the combination of dead load and imposed load is likely to be excessive, consideration should be given to pre-camber the beams, trusses and girders. The value of desired camber shall be specified in design drawing. Generally, for spans greater than 25 m, a camber approximately equal to the deflection due to dead loads plus half the imposed load may be used. The deflection of a member shall be calculated without considering the impact factor or dynamic effect of the loads on deflection. Roofs, which are very flexible, shall be designed to withstand any additional load that is likely to occur as a result of ponding of water or accumulation of snow or ice.

12.6.2 *Vibration*

Suitable provisions in the design shall be made for the dynamic effects of imposed loads, impact loads and vibration due to machinery operating loads. In severe cases possibility of resonance, fatigue or unacceptable vibrations shall be investigated. Unusually flexible structures (generally the height to effective width of lateral load resistance system exceeding 5 : 1) shall be investigated for lateral vibration under dynamic wind loads. Structures subjected to large number of cycles of loading shall be designed against fatigue failure, as specified under **19**. Floor vibration effect shall be considered using specialist literature (*see* Annex C).

12.6.3 *Durability*

Factors that affect the durability of the buildings, under conditions relevant to their intended life, are listed below:

a) Environment;

b) Degree of exposure;

c) Shape of the member and the structural detail;

d) Protective measure; and

e) Ease of maintenance.

The durability of steel structures shall be ensured by following recommendations given under **21**. Specialist literature may be referred to for more detailed and additional information in design for durability.

Table 6 Deflection Limits

(*Clause* 12.6.1)

Sl No.	Type of Building	Deflection	Design Load	Member	Supporting	Maximum Deflection

					Brittle cladding	Height/500
			Wind load	Inter-storey drift	—	Storey height/300

---

1) Crane supplier may be consulted for higher values

12.6.4 *Fire Resistance*

Fire resistance of a steel member is a function of its mass, its geometry, and the actions to which it is subjected, its structural support condition, fire protection measures adopted and the fire to which it is exposed. Design provisions to resist fire are briefly discussed under **22**. Specialist literature may be referred to for more detailed information in design of fire resistance of steel structures.

13 DESIGN OF TENSION MEMBERS

13.1 Tension Members

Tension members are linear members in which axial forces act to cause elongation (stretch). Such members can sustain loads up to the ultimate load, at which stage they may fail by rupture at a critical section. However, if the gross area of the member yields over a major portion of its length before the rupture load is reached, the member may become non-functional due to excessive elongation. Plates and other rolled sections in tension may also fail by block shear of end bolted regions (*see* **13.4.1**).

The factored design tension T, in the members shall satisfy the following requirement:

$$T < T_d$$

where

T_d = Design strength of the member.

The design strength of a member under axial tension, T_d, is the lowest of the design strength due to yielding of gross section, T_{dg}; rupture strength of critical section, T_{dn}; and block shear T_{db}, given in **13.2**, **13.3** and **13.4**, respectively.

13.2 Design Strength Due to Yielding of Gross Section

The design strength of members under axial tension, T_{dg}, as governed by yielding of gross section, is given by:

$$T_{dg} = A_g f_y / \gamma_{m0}$$

where

A_g = gross area of cross section;

f_y = yield stress of the material; and

γ_{m0} = partial safety factor for failure in tension by yielding (*see* Table 5).

13.3 Design Strength Due to Rupture of Critical Section

13.3.1 *Plates*

The design strength in tension of a plate, T_{dn}, as governed by rupture of net cross sectional area, A_n, at the holes is given by:

$$T_{dn} = 0.9\, A_n f_u / \gamma_{m1}$$

where

A_n = net effective area of the member given by;

f_u = ultimate stress of the material; and

γ_{m1} = partial safety factor for failure at ultimate stress (*see* Table 5).

$$A_n = \left[b - nd_h + \sum \frac{p_{si}^2}{4g_i} \right] t$$

where

b, t = width and thickness of the plate, respectively;

d_h = diameter of the bolt hole (2 mm in addition to the diameter of the hole, in case of directly punched holes);

g = gauge length between the bolt holes, as shown in Fig. 5;

i = subscript for summation of all the inclined legs;

n = number of bolt holes in the critical section; and

p_s = staggered pitch length between line of bolt holes, as shown in Fig. 5.

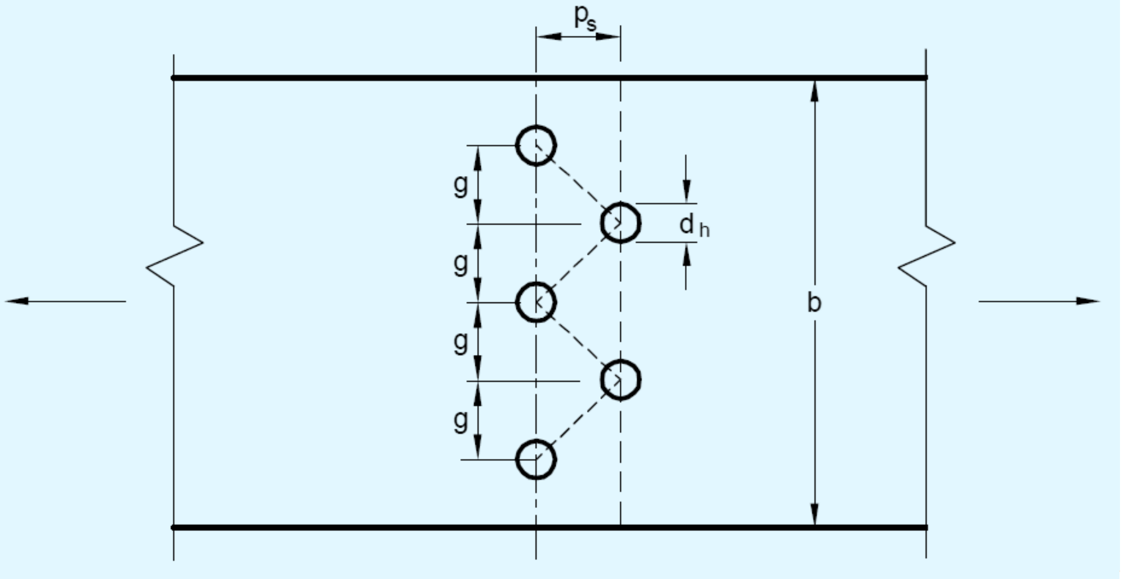

FIG. 5 PLATES WITH BOLTS HOLES IN TENSION

13.3.2 *Threaded Rods*

The design strength of threaded rods in tension, T_{dn}, as governed by rupture is given by:

$$T_{dn} = 0.9 A_c f_u / \gamma_{m1}$$

where

A_c = net root area at the threaded section.

13.3.3 *Single Angles*

The rupture strength of an angle connected through one leg is affected by shear lag. The design strength, $T_{dn,}$ as governed by rupture at net section is given by:

$$T_{dn} = 0.9 A_{nc} f_u / \gamma_{m1} + \beta A_{go} f_y / \gamma_{m0}$$

where

$$\beta = 1.4 - 0.076\,(w/t)\,(f_y/f_u)\,(b_s/L_c) \leq (0.9 f_u \gamma_{m0}/f_y \gamma_{m1}) \geq 0.7$$

where

A_{go} = gross area of the outstanding leg;

A_n = net area of the total cross section

A_{nc} = net area of the connected leg;

b_s = shear lag width, as shown in Fig. 6;

L_c = length of the end connection, that is the distance between the outermost bolts in the end joint measured along the load direction or length of the weld along the load direction;

t = thickness of the leg; and

w = outstand leg width.

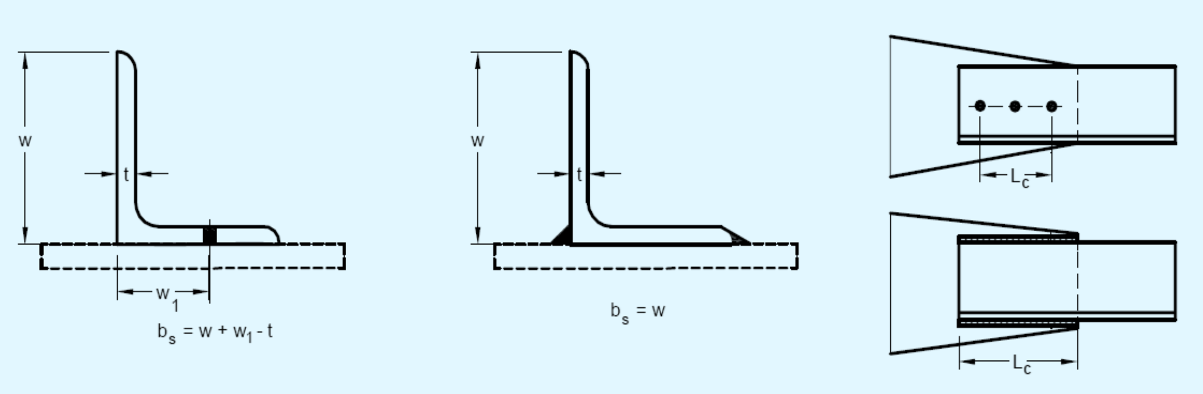

FIG. 6 ANGLES WITH SINGLE LEG CONNECTIONS

13.3.4 *Other Section*

The rupture strength, T_{dn}, of the double angles, channels, I-sections and other rolled steel sections, connected by one or more elements to an end gusset is also governed by shear lag effects. The design tensile strength of such sections as governed by tearing of net section may also be calculated using equation in **13.3.3**, where β is calculated based on the shear lag distance, b_s, taken from the farthest edge of the outstanding leg to the nearest bolt/weld line in the connected leg of the cross section.

13.4 Design Strength Due to Block Shear

The strength as governed by block shear at an end connection of plates and angles is calculated as given in **13.4.1**.

13.4.1 *Bolted Connections*

The block shear strength, T_{db} of connection shall be taken as the smaller of,

$$T_{db} = \left[A_{vg}\, f_y/(\sqrt{3}\,\gamma_{m0}) + 0.9 A_{tn}\, f_u/\gamma_{m1} \right]$$

or

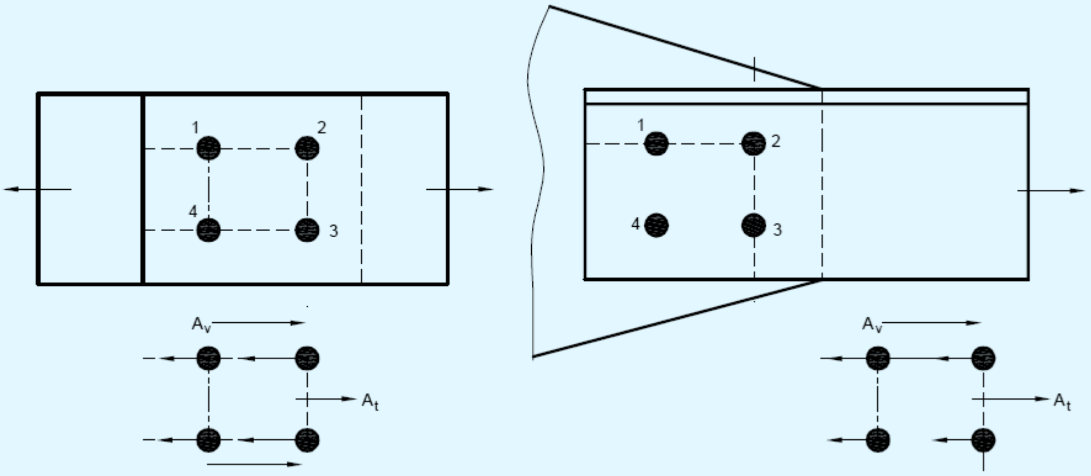
$$T_{db} = \left[0.9 A_{vn}\, f_u/(\sqrt{3}\,\gamma_{m1}) + A_{tg}\, f_y/\gamma_{m0} \right]$$

where

A_{tg}, A_{tn} = minimum gross and net area in tension from the bolt hole to the toe of the angle, end bolt line, perpendicular to the line of force, respectively (2-3 as shown in Fig. 7(B);

A_{vg}, A_{vn} = minimum gross and net area in shear along bolt line parallel to external force, respectively (1-2 and 3-4 as shown in Fig. 7(A) and 1-2 as shown in Fig. 7(B); and

f_u, f_y = ultimate and yield stress of the material, respectively.



7A PLATE

7B ANGLE

FIG. 7 BLOCK SHEAR FAILURE

13.4.2 *Welded Connection*

The block shear strength, T_{db} shall be checked for welded end connections by taking an appropriate section in the member around the end weld, which can shear off as a block.

14 DESIGN OF COMPRESSION MEMBERS

14.1 Design Strength

14.1.1 Common hot rolled and built-up steel members used for carrying axial compression, usually fail by flexural buckling. The buckling strength of these members is affected by residual stresses, initial bow and accidental eccentricities of load. To account for all these factors, the strength of members subjected to axial compression is defined by buckling class a_0, a, b, c, or d as given Table 7.

14.1.2 The factored design compression, P in members shall satisfy the following requirement:

$$P < P_d$$

$$P_d = A_e f_{cd}$$

where

P_d = design strength of the member

A_e = effective sectional area as defined in **14.3.2**; and

f_{cd} = design compressive stress, given by.

$$f_{\mathrm{cd}} = \frac{\chi f_y}{\gamma_{\mathrm{m0}}} \leq f_y / \gamma_{\mathrm{m0}}$$

χ = stress reduction factor for different buckling class, slenderness ratio and yield stress and mode of buckling as given in **14.1.2.1** or **14.1.2.2**, as applicable (*see* Table 8); and

γ_{m0} = partial safety factor for material strength.

NOTE — Calculated values of design compressive stress, f_{cd} for different buckling classes are given in Table 9.

14.1.2.1 *Reduction factor for flexural buckling* (*See also* Table 8)

$$\chi = \frac{1}{\phi + \sqrt{\phi^2 + \lambda^2}}$$

$\phi = 0.5[1 + \alpha(\lambda - 0.2) + \lambda^2]$

λ = non-dimensional effective slenderness ratio:

$$= \sqrt{f_y / f_{\mathrm{cr}}} = \sqrt{f_{\mathrm{y}} \left(\frac{KL}{r}\right)^2 / \pi^2 E}$$

f_{cr} = Euler buckling stress about the relevant axis $= \dfrac{\pi^2 E}{(KL/r)^2}$

where

KL/r = effective slenderness ratio or ratio of effective length, KL to appropriate radius of gyration, r; and

α = imperfection factor given in Table 7.

14.1.2.2 *Reduction factor for torsional and torsional flexural buckling*

$$\chi = \frac{1}{\phi + \sqrt{\phi^2 + \lambda_{\mathrm{TF}}^2}}$$

$$\phi = 0.5\left[1 + \left(\frac{\lambda_{\mathrm{TF}}}{\lambda_{\mathrm{y}}}\right)^2 . \alpha_{\mathrm{TF}}\left(\lambda_{\mathrm{y}} - 0.2\right) + \lambda_{\mathrm{TF}}^2\right]$$

$$\alpha_{\mathrm{TF}} = \alpha \sqrt{\frac{A\, f_{\mathrm{y}}(i_{\mathrm{p}}^2 + d_{\mathrm{y}}^2)}{6.25\, G\, I_{\mathrm{T}}}}$$

$$\lambda_{\mathrm{TF}} = \sqrt{f_y / f_{\mathrm{crTF}}}$$

$$\lambda_{\mathrm{Y}} = \sqrt{f_y / f_{\mathrm{cr,y}}}$$

where

α = is the imperfection factor given in Table 7;

d_y = is the distance between intermediate lateral support and shear centre at the section;

i_p = is the polar radius of gyration given by;

i_{p}^2 = $(I_{\mathrm{y}} + I_z)/A$;

I_{T} = is the torsional constant of the cross section;

I_y, I_z = is the moment of inertia about y and z axis, respectively and shear centre;

λ_{TF} = non-dimensional effective slenderness ratio; and

λ_y = non-dimensional effective slenderness ratio.

f_{cry} = flexural buckling stress about the y axis ; and

f_{crTF} = torsional flexural buckling stress at the extreme compression fibre (Annex E).

14.1.2.3 The classification of different sections under different buckling class a_0, a, b, c or d, is given in Table 10. The stress reduction factor χ, and the design compressive stress f_{cd}, for different buckling class, yield stress, and effective slenderness ratio is given in Table 8 and Table 9 for convenience. The curves corresponding to different buckling class are presented in non-dimensional form, in Fig. 8.

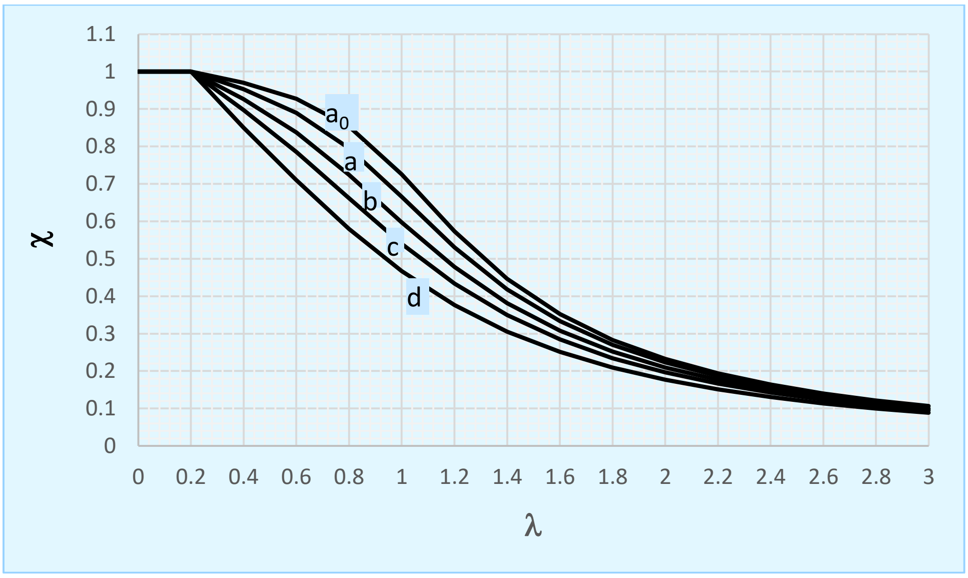

FIG. 8 COLUMN BUCKLING CURVES

14.2 Effective Length of Compression Members

14.2.1 The effective length *KL,* is calculated from the actual length *L*, of the member, considering the rotational and relative translational boundary conditions at the ends. The actual length shall be taken as the length from centre to centre of its intersections with the supporting members in the plane of the buckling deformation. In the case of a member with a free end, the free standing length from the centre of the intersecting member at the supported end, shall be taken as the actual length.

14.2.2 *Effective Length*

Where the boundary conditions in the plane of buckling can be assessed, the effective length, *KL* can be calculated on the basis of Table 11. Where frame analysis does not consider the equilibrium of a framed structure in the deformed shape (second-order analysis or advanced analysis), the effective length of compression members in such cases can be calculated using the procedure given in **D-1**. The effective length of stepped column in single storey buildings can be calculated using the procedure given in **D-2**.

14.2.3 *Eccentric Beam Connection*

In cases where the beam connections are eccentric in plan with respect to the axes of the column, the same conditions of restraint as in concentric connection shall be deemed to apply, provided the connections are carried across the flange or web of the columns as the case may be, and the web of the beam lies within, or in direct contact with the column section. Where practical difficulties prevent this, the effective length shall be taken as equal to the distance between points of restraint in non-sway frames.

14.2.4 *Compression Members in Trusses*

In the case of bolted, riveted or welded trusses and braced frames, the effective length, KL, of the compression members shall be taken as 0.7 to 1.0 times the distance between centres of connections, depending on the degree of end restraint provided. In the case of members of trusses buckling in the plane perpendicular to the plane of the truss, the effective length, KL shall be taken as the distance between the centres of intersection. The design of angle struts shall be as specified in **14.5**.

14.3 Design Details

14.3.1 *Thickness of Plate Elements*

Classification of members on the basis of the thickness of constituent plate elements shall satisfy the width-thickness ratio requirements specified in Table 2.

14.3.2 *Effective Sectional Area, A_e*

Except as modified in **10.8.2** (Class 4), the gross sectional area shall be taken as the effective sectional area for all compression members fabricated by welding, bolting and riveting so long as the section is semi-compact or better. Holes not fitted with rivets, bolts or pins shall be deducted from gross area to calculate effective sectional area.

14.3.3 *Eccentricity for Stanchions and Columns*

14.3.3.1 For the purpose of determining the stress in a stanchion or column section, the beam reactions or similar loads shall be assumed to be applied at an eccentricity of 100 mm from the face of the section or at the centre of bearing whichever dimension gives the greater eccentricity, and with the exception of the following two cases:

a) In the case of cap connection, the load shall be assumed to be applied at the face of the column or stanchion section or at the edge of packing, if used towards the span of the beam; and

b) In the case of a roof truss bearing on a cap, no eccentricity be taken for simple bearings without connections capable of developing any appreciable moment. In case of web member connection with face, actual eccentricity is to be considered.

Table 11 Effective Length of Prismatic Compression Members

(*Clause* 14.2.2)

Boundary Conditions				**Schematic Representation**	**Effective Length**
At One End		At the Other End			
Translation	Rotation	Translation	Rotation		
(1)	(2)	(3)	(4)	(5)	(6)
Restrained	Restrained	Free	Free		2.0L
Restrained	Free	Free	Restrained		
Restrained	Free	Restrained	Free		1.0L
Restrained	Restrained	Free	Restrained		1.2L
Restrained	Restrained	Restrained	Free		0.8L
Restrained	Restrained	Restrained	Restrained		0.65L

NOTE — L is the unsupported length of the compression member (*see* **13.2.1**).

14.3.3.2 In continuous columns, the bending moments due to eccentricities of loading on the columns at any floor may be divided equally between the columns above and below that floor level, provided that the moment of inertia of one column section, divided by its effective length does not exceed 1.5 times the corresponding value of the other column. Where this ratio is exceeded, the bending moment shall be divided in proportion to the moment of inertia of the column sections divided by their respective effective lengths.

14.3.4 *Splices*

14.3.4.1 Where the ends of compression members are prepared for bearing over the whole area, they shall be spliced to hold the connected members accurately in position, and to resist bending or tension, if present. Such splices should maintain the intended member stiffness about each axis. Splices should be located as close to the point of inflection as possible. Otherwise their capacity should be adequate to carry magnified moment (*see* **16.3.2.2**). The ends of compression members faced for bearing shall invariably be machined to ensure perfect contact of surfaces in bearing.

14.3.4.2 Where such members are not faced for complete bearing, the splices shall be designed to transmit all the forces to which the members are subjected.

14.3.4.3 Wherever possible, splices shall be proportioned and arranged so that the centroidal axis of the splice coincides as nearly as possible with the centroidal axes of the members being jointed, in order to avoid eccentricity; but where eccentricity is present in the joint, the resulting stress shall be accounted for.

14.4 Column Bases

14.4.1 *General*

Column bases should have sufficient stiffness and strength to transmit axial force, bending moments and shear forces at the base of the columns to their foundation without exceeding the load carrying capacity of the supports. Anchor bolts and shear keys should be provided wherever necessary. Shear resistance at the proper contact surface between steel base and concrete/grout may be calculated using a friction coefficient of 0.45. Design recommendations of anchor bolts in concrete foundations may be referred as per good practice [C-6A(38)].

The nominal bearing pressure between the base plate and the support below may be determined on the basis of linearly varying distribution of pressure. The maximum bearing pressure on concrete under the limit states design load should not exceed the bearing strength equal to $0.3f_{ck}\,[\sqrt{(A_1/A_2)}]$ and $0.9f_{ck}$, whichever is smaller, where f_{ck} is the smaller of characteristic cube strength of concrete or bedding material, A_1 is the area of concrete pedestal on which the base plate is sitting, and A_2 is the surface area of the steel base plate transferring the load to the concrete pedestal.

If the size of the base plate is larger than that required to limit the bearing pressure on the base support, an equal projection, *c* of the base plate beyond the face of the column and gusset may be taken as effective in transferring the column load as given in Fig. 9, such that bearing pressure on the effective area does not exceed bearing capacity of concrete base.

14.4.2 *Gusseted Bases*

For stanchion with gusseted bases, the gusset plates, angle cleats, stiffeners, fastenings, etc, in combination with the bearing area of the shaft, shall be sufficient to take the loads, bending moments and reactions to the base plate without exceeding specified strength. All the bearing surfaces shall be machined to ensure perfect contact.

14.4.2.1 Where the ends of the column shaft and the gusset plates are not faced for complete bearing, the welds, fastenings connecting them to the base plate shall be sufficient to transmit all the forces to which the base is subjected.

14.4.2.2 *Column and base plate connections*

Where the end of the column is connected directly to the base plate by means of full penetration butt welds, the connection shall be deemed to transmit to the base all the forces and moments to which the column is subjected.

14.4.3 *Slab Bases*

Columns with slab bases need not be provided with gussets, but sufficient fastenings shall be provided to retain the parts securely in place and to resist all moments and forces, other than direct compression, including those arising during transit, unloading and erection. Minimum of four number of anchor bolts shall be used to anchor column bases to foundation and minimum of six numbers in the case of slab bases transferring earthquake forces.

14.4.3.1 The minimum thickness, t_s, of rectangular slab bases, supporting columns under axial compression shall be

$$t_s = \sqrt{2.5\,w(a^2 - 0.3b^2)\gamma_{m0} / f_y} \quad > t_f$$

where

a, b = larger and smaller projection, respectively of the slab base beyond the rectangle circumscribing the column;

t_f = flange thickness of compression member; and

w = uniform pressure from below on the slab base under the factored load axial compression.

When only the effective area of the base plate is used as in **14.4.1**, c^2 may be used in the above equation (*see* Fig. 9) instead of ($a^2 - 0.3b^2$).

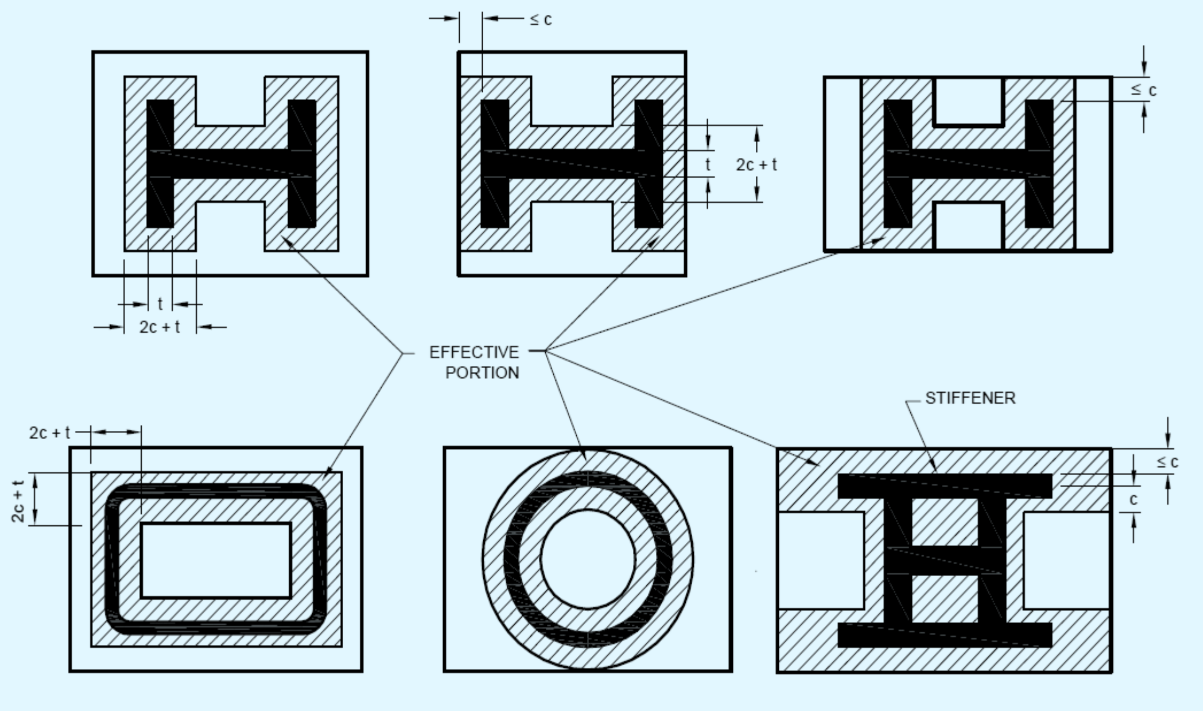

FIG. 9 EFFECTIVE AREA OF A BASE PLATE

14.4.3.2 When the slab does not distribute the column load uniformly, due to eccentricity of the load etc, special calculation shall be made to show that the base is adequate to resist the moment due to the non-uniform pressure from below.

14.4.3.3 Bases for bearing upon concrete or masonry need not be machined on the underside.

14.4.3.4 In cases where the cap or base is fillet welded directly to the end of the column without boring and shouldering, the contact surfaces shall be machined to give a perfect bearing and the welding shall be sufficient to transmit the forces as required in **14.4.3**. Where full strength butt welds are provided, machining of contact surfaces is not required.

14.5 Angle Struts

14.5.1 *Single Angle Struts*

The compression in single angles may be transferred either concentrically to its centroid through the end connections or eccentrically by connecting one of its legs to a gusset or adjacent member.

14.5.1.1 *Concentric loading*

When a single angle is concentrically loaded in compression, the design strength may be evaluated using **14.1.2**, by calculating the non-dimensional slenderness ratio, λ_{vv}, for buckling about the minor axis, *v-v*, as given by:

$$\lambda_{vv} = \frac{\left(\dfrac{l_{vv}}{r_{vv}}\right)}{\varepsilon\sqrt{\dfrac{\pi^2 E}{250}}}$$

r_{vv} = radius of gyration of the angle section about the minor axis; and

l_{vv} = laterally unsupported length preventing translation normal to the minor axis

14.5.1.2 *Loaded through one leg*

The design strength of single angle members loaded in compression through one of its legs, f_{cde}, is affected by flexural torsional buckling and bending. The design compressive strength of such eccentrically loaded angle members, *in lieu of* a more exact second order design under combined bending axial compression, may be evaluated approximately as given below.

The design compressive strength, of single angles loaded through gusset connection to one leg parallel to the *a-a* axis (*a-a* axis being either the *z-z* or the *y-y* axis, depending on which leg is connected to the gusset) of the member may be calculated as:

$$f_{cde} = K_f \chi_{aa} f_y / \gamma_{m0} \quad \leq f_{cd} \text{ (given in 14.1.2)}$$

where

f_{cde} = Design compressive stress of single angle.

K_f = $k_1 + k_2\lambda_{aa} + k_3\lambda_{\phi}$;

χ_{aa} = Stress reduction factor (*see* Table 8) for buckling class ‘b’, calculated as per **14.1.2.1**, using the non-dimensional slenderness ratio, λ_{aa}.

where

k_1, k_2, k_3 = constants depending upon the end condition, as given in Table 12; and

K_f = modification factor to account for eccentric end connection.

$$\lambda_{aa} = \frac{\left(\dfrac{l_{aa}}{r_{aa}}\right)}{\varepsilon\sqrt{\dfrac{\pi^2 E}{250}}}$$

$$\lambda_{\varphi} = \frac{(b_1 + b_2)/2t}{\varepsilon\sqrt{\frac{\pi^2 E}{250}}}$$

b_1, b_2 = width of the connected and outstanding legs of the angle, respectively;

l_{aa} = centre to centre length of the lateral support preventing translation of the member perpendicular to a-a axis (a-a axis being either the z-z or the y-y axis, depending on which leg is connected to the gusset);

r_{aa} = radius of gyration of the angle member about the *a-a* axis (*a-a* axis being either the *z-z* or the *y-y* axis, depending on which leg is connected to the gusset), parallel to the plane of the end gusset plates;

t = thickness of the leg; and

ε = is the yield stress ratio, $\sqrt{\frac{250}{f_y}}$, f_y being in MPa

Table 12 Constants k_1, k_2, and k_3

---

[1] In-plane rotational restraint provided to the gusset by the supporting member. For partial restraint, k_f can be interpolated between the results for fixed and hinged cases.

14.5.2 *Double Angle Struts*

14.5.2.1 For double angle discontinuous struts, connected back to back, on opposite sides of the gusset or a section, by not less than two bolts or rivets in line along the angles at each end, or by the equivalent in welding, the load may be regarded as applied axially. The effective length, *KL*, in the plane of end gusset shall be taken as between 0.7 times and 0.85 times the distance between intersections, depending on the degree of the restraint provided. The effective length, *KL*, in the plane perpendicular to that of the end gusset, shall be taken as equal to the distance between centres of intersections. The calculated average compressive stress shall not exceed the values based on **14.1.2**. The angles shall be connected together over their lengths so as to satisfy the requirements of **14.8** and **17.2.5**.

14.5.2.2 Double angle discontinuous struts connected back-to-back, to one side of a gusset or section by one or more bolts or rivets in each angle, or by the equivalent in welding, shall be designed in accordance with **14.5.1** and the angles shall be connected together over their lengths so as to satisfy the requirements of **14.8** and **17.2.5**.

14.5.3 *Continuous Members*

Double angle continuous struts such as those forming the flanges, chords or ties of trusses or trussed girders, or the legs of towers shall be designed as axially loaded compression members, and the effective length shall be taken in accordance with **14.2.4**.

14.5.4 *Combined Stresses*

In addition to axial loads, if the struts carry loads which cause transverse bending, the combined bending and axial stresses shall be checked in accordance with **16.3**. For determining the permissible axial and bending stresses, the effective length shall be taken in accordance with the **14.2** and **15.3**.

14.6 Laced Columns

14.6.1 *General*

14.6.1.1 Members comprising two main components laced and tied, should where practicable, have a radius of gyration about the axis perpendicular to the plane of lacing not less than the radius of gyration about the axis parallel to the plane of lacing [*see* Fig.10(A) and Fig. 10(B)].

14.6.1.2 As far as practicable, the lacing system shall be uniform throughout the length of the column.

14.6.1.3 Except for tie plates as specified in **14.7**, double laced systems [*see* Fig. 10(B)] and single laced systems [*see* Fig. 10(A)] on opposite sides of the main components shall not be combined with cross members (ties) perpendicular to the longitudinal axis of the strut [*see* Fig. 10(C)], unless all forces resulting from deformation of the strut members are calculated and provided for in the design of lacing and its fastenings.

14.6.1.4 Single laced systems, on opposite faces of the components being laced together shall preferably be in the same direction so that one is the shadow of the other, instead of being mutually opposed in direction.

14.6.1.5 The effective slenderness ratio, $(KL/r)_e$, of laced columns shall be taken as 1.05 times the $(KL/r)_0$, the actual maximum slenderness ratio, in order to account for shear deformation effects.

14.6.2 *Width of Lacing Bars*

In bolted/riveted construction, the minimum width of lacing bars shall be three times the nominal diameter of the end bolt/rivet.

14.6.3 *Thickness of Lacing Bars*

The thickness of flat lacing bars shall not be less than one-fortieth of its effective length for single lacings and one-sixtieth of the effective length for double lacings.

Rolled sections or tubes of equivalent strength may be permitted instead of flats, for lacings.

14.6.4 *Angle of Inclination*

Lacing bars, whether in double or single systems, shall be inclined at an angle not less than 40º nor more than 70º to the axis of the built-up member.

14.6.5 *Spacing*

14.6.5.1 The maximum spacing of lacing bars, whether connected by bolting, riveting or welding, shall also be such that the maximum slenderness ratio of the components of the main member (a_1/r_1), between consecutive lacing connections is not greater than 50 or 0.7 times the most unfavourable slenderness ratio of the member as a whole, whichever is less, where a_1 is the unsupported length of the individual member between lacing points, and r_1 is the minimum radius of gyration of the individual member being laced together.

14.6.5.2 Where lacing bars are not lapped to form the connection to the components of the members, they shall be so connected that there is no appreciable interruption in the triangulation of the system.

14.6.6 *Design of Lacings*

14.6.6.1 The lacing shall be proportioned to resist a total transverse shear, V_t, at any point in the member, equal to at least 2.5 percent of the axial force in the member and shall be divided equally among all transverse-lacing systems in parallel planes.

14.6.6.2 For members carrying calculated bending stress due to eccentricity of loading, applied end moments and/or lateral loading, the lacing shall be proportioned to resist the actual shear due to bending, in addition to that specified in **14.6.6.1**.

14.6.6.3 The slenderness ratio, *KL/r*, of the lacing bars shall not exceed 145. In bolted/riveted construction, the effective length of lacing bars for the determination of the design strength shall be taken as the length between the inner end fastener of the bars for single lacing, and as 0.7 of this length for double lacings effectively connected at intersections. In welded construction, the effective lengths shall be taken as 0.7 times the distance between the inner ends of welds connecting the single lacing bars to the members.

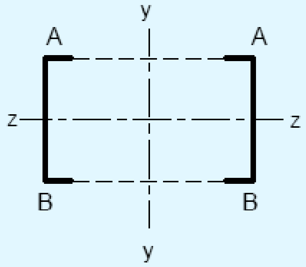
NOTE — The required section for lacing bars as compression/tension members shall be determined by using the appropriate design stresses, f_{cd} subject to the requirements in **14.6.3** to **14.6.6** and T_d in **13.1**.

14.6.7 *Attachment to Main Members*

The bolting, riveting or welding of lacing bars to the main members shall be sufficient to transmit the force calculated in the bars. Where welded lacing bars overlap the main members, the amount of lap measured along either edge of the lacing bar shall be not less than four times the thickness of the bar or the thickness of the element of the members to which it is connected, whichever is less. The welding should be sufficient to transmit the load in the bar and shall, in any case, be provided along each side of the bar for the full length of lap.

14.6.8 *End Tie Plates*

Laced compression members shall be provided with tie plates as per **14.7** at the ends of lacing systems and at intersection with other members/stays and at points where the lacing systems are interrupted.



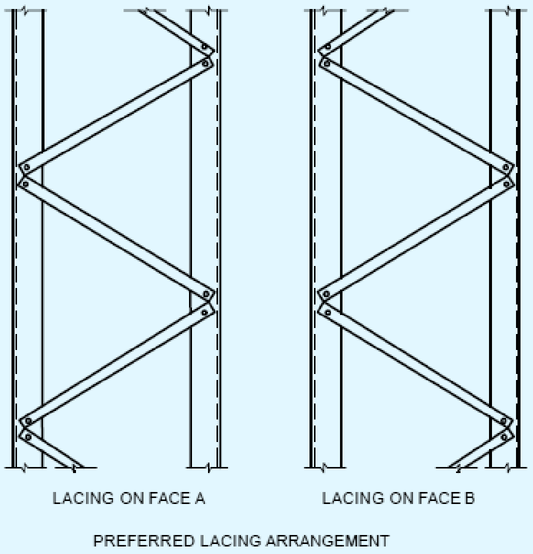


Fig. 10(A) Single Laced Syste

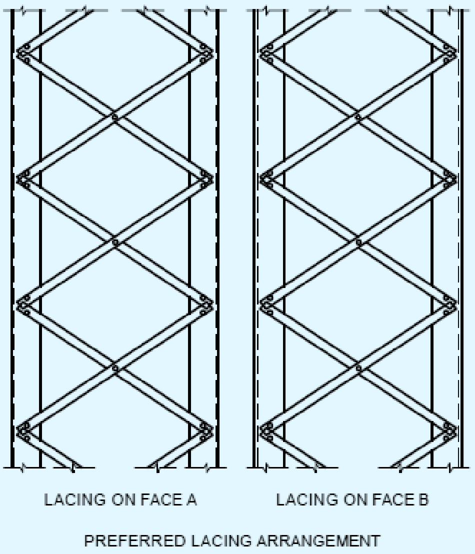

Fig. 10(B) Double Laced System

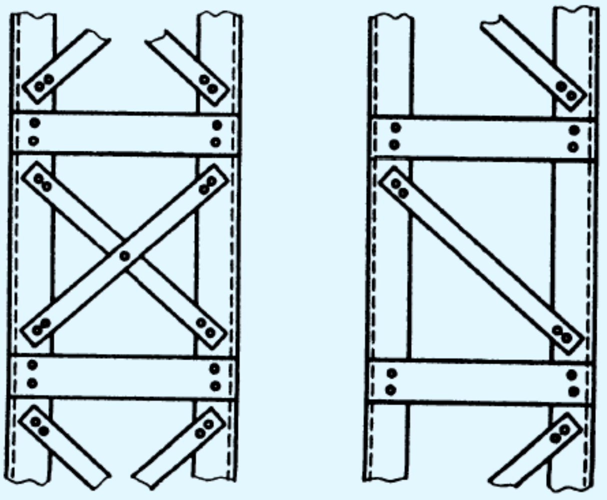

FIG. 10(C) DOUBLE LACED AND SINGLE LACED SYSTEM COMBINED WITH CROSS MEMBERS

FIG. 10 LACED COLUMNS

14.7 Battened Columns

14.7.1 *General*

14.7.1.1 Compression members composed of two main components battened should preferably have the individual members of the same cross section and symmetrically disposed about their major axis. Where practicable, the compression members should have a radius of gyration about the axis perpendicular to the plane of the batten not less than the radius of gyration about the axis parallel to the plane of the batten (*see* Fig. 11).

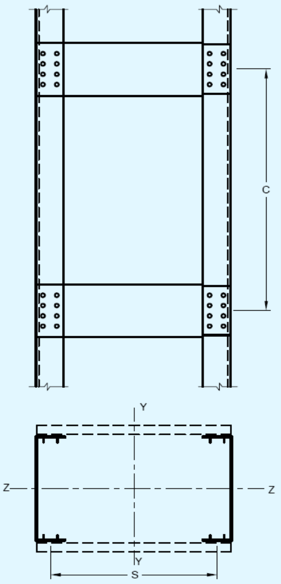

FIG. 11 BATTEN COLUMN SECTION

14.7.1.2 Battened compression members, not complying with the requirements specified in this Section or those subjected to eccentricity of loading, applied moments or lateral forces in the plane of the battens (*see* Fig. 11), shall be designed according to the exact theory of elastic stability or empirically, based on verification by tests.

NOTE — If the column section is subjected to eccentricity or other moments about an axis perpendicular to battens, the battens and the column section should be specially designed for such moments and shears.

14.7.1.3 The battens shall be placed opposite to each other at each end of the member and at points where the member is stayed in its length and as far as practicable, be spaced and proportioned uniformly throughout. The number of battens shall be such that the member is divided into not less than three bays within its actual length from centre to centre of end connections.

14.7.1.4 The effective slenderness ratio $(KL/r)_e$ of battened columns, shall be taken as 1.1 times the $(KL/r)_0$, the maximum actual slenderness ratio of the column, to account for shear deformation effects.

14.7.2 *Design of Battens*

14.7.2.1 *Battens*

Battens shall be designed to carry the bending moments and shear forces arising from transverse shear force V_t equal to 2.5 percent of the total axial force on the whole compression member, at any point in the length of the member, divided equally between parallel planes of battens. Battened member carrying calculated bending moment due to eccentricity of axial loading, calculated end moments or lateral loads parallel to the plane of battens, shall be designed to carry actual shear in addition to the above shear. The main members shall also be checked for the same shear force and bending moments as for the battens.

Battens shall be of plates, angles, channels, or I-sections and at their ends shall be riveted, bolted or welded to the main components so as to resist simultaneously a shear $V_b = V_t\ C/NS$ along the column axis and a moment $M = V_t C/2N$ at each connection,

where

C = distance between centre-to-centre of battens, longitudinally;

N = number of parallel planes of battens;

S = minimum transverse distance between the centroid of the rivet/bolt group/welding connecting the batten to the main member; and

V_t = transverse shear force as defined above.

14.7.2.2 *Tie plates*

Tie plates are members provided at the ends of battened and laced members, and shall be designed by the same method as battens. In no case shall a tie plate and its fastenings be incapable of carrying the forces for which the lacing or batten has been designed.

14.7.2.3 *Size*

When plates are used for battens, the end battens and those at points where the member is stayed in its length shall have an effective depth, longitudinally, not less than the perpendicular distance between the centroids of the main members. The intermediate battens shall have an effective depth of not less than three quarters of this distance, but in no case shall the effective depth of any batten be less than twice the width of one member, in the plane of the battens. The effective depth of a batten shall be taken as the longitudinal distance between outermost bolts, rivets or welds at the ends. The thickness of batten or the tie plates shall be not less than one fiftieth of the distance between the innermost connecting lines of rivets, bolts or welds, perpendicular to the main member.

14.7.2.4 The requirement of bolt size and thickness of batten specified above does not apply when angles, channels or I-sections are used for battens with their legs or flanges perpendicular to the main member. However, it should be ensured that the ends of the compression members are tied to achieve adequate rigidity.

14.7.3 *Spacing of Battens*

In battened compression members where the individual members are not specifically checked for shear stress and bending moments, the spacing of battens, centre-to-centre of its end fastenings, shall be such that the slenderness ratio (KL/r) of any component over that distance shall be not greater than 50 nor greater than 0.7 times the slenderness ratio of the member as a whole about its z-z axis (parallel to the battens).

14.7.4 *Attachment to Main Members*

14.7.4.1 *Welded connections*

Where tie or batten plates overlap the main members, the amount of lap shall be not less than four times the thickness of the plate. The length of weld connecting each edge of the batten plate to the member shall, in aggregate, be not less than half the depth of the batten plate. At least one-third of the weld shall be placed at each end of this edge. The length of weld and depth of batten plate shall be measured along the longitudinal axis of the main member.

In addition, the welding shall be returned along the other two edges of the plates transversely to the axis of the main member for a length not less than the minimum lap specified above.

14.8 Compression Members Composed of Two Components Back-to-Back

14.8.1 Compression members composed of two angles, channels, or tees back-to-back in contact or separated by a small distance, shall be connected together by riveting, bolting or welding so that the ratio of most unfavorable slenderness of each member between the intermediate connections is not greater than 40 or 0.6 times the most unfavorable ratio of slenderness of the strut as a whole, whichever is less [*see* **17**].

14.8.2 In no case shall the ends of the strut be connected together with less than two rivets or bolts or their equivalent in welding, and there shall be not less than two additional connections in between, spaced equidistant along the length of the strut. Where the members are separated back-to-back, the rivets or bolts through these connections shall pass through solid washers or packing in between. Where the legs of the connected angles or the connected tees are 125 mm wide or more, or where webs of channels are 150 mm wide or over, not less than two rivets or bolts shall be used in each connection, one on line of each gauge mark.

14.8.3 Where these connections are made by welding, solid packing shall be used to effect the jointing unless the members are sufficiently close together to permit direct welding, and the members shall be connected by welding along both pairs of edges of the main components.

14.8.4 The rivets, bolts or welds in these connections shall be sufficient to carry the shear force and moments, if any, specified for battened struts (*see* **14.7.3**), and in no case shall the rivets or bolts be less than 16 mm diameter for members up to and including 10 mm thick; 20 mm diameter for members up to and including 16 mm thick; and 22 mm diameter for members over 16 mm thick.

Compression members connected by such riveting, bolting or welding shall not be subjected to transverse loading in a plane perpendicular to the riveted, bolted or welded surfaces.

14.8.5 Where the components are in contact back-to-back, the spacing of the rivets, bolts or intermittent welds shall not exceed the maximum spacing for compression members as given under **17**.

15 DESIGN OF MEMBERS SUBJECTED TO BENDING

15.1 General

Members subjected to predominant bending shall have adequate design strength to resist bending moment, shear force, and concentrated forces imposed upon and their combinations. Further, the members shall satisfy the deflection limitation presented under **12**, as serviceability criteria. Member subjected to other forces in addition to bending or biaxial bending shall be designed in accordance with the provisions under **16**.

15.1.1 *Effective Span of Beams*

The effective span of a beam shall be taken as the distance between the centres of the supports, except where the point of application of the reaction is taken as eccentric at the support, when it shall be permissible to take the effective span as the length between the assumed lines of the reactions.

15.2 Design Strength in Bending (Flexure)

The design bending strength of beam, adequately supported against lateral torsional buckling (laterally supported beam) is governed by the yield stress (*see* 15.2.1). When a beam is not adequately supported against lateral buckling (laterally un-supported beams) the design bending strength may be governed by lateral torsional buckling strength (*see* 15.2.2).

The factored design moment, M at any section, in a beam due to external actions, shall satisfy:

$$M \leq M_{\mathrm{d}}$$

where

M_{d} = design bending strength of the section, calculated as given in 15.2.1.2.

15.2.1 *Laterally Supported Beam*

A beam may be assumed to be adequately supported at the supports, provided the compression flange has full lateral restraint and nominal torsional restraint at supports supplied by web cleats, partial depth end plates, fin plates or continuity with the adjacent span. Full lateral restraint to compression flange may be assumed to exist if the frictional or other positive restraint of a floor connection to the compression flange of the member is capable of resisting a lateral force not less than 2.5 percent of the maximum force in the compression flange of the member. This may be considered to be uniformly distributed along the flange, provided gravity loads constitute the dominant loading on the member and the floor construction is capable of resisting this lateral force.

The design bending strength of a section which are not susceptible to web buckling under shear before yielding (where $d/t_{\mathrm{w}} \leq 67\varepsilon$) shall be determined according to 15.2.1.2.

15.2.1.1 *Section with webs susceptible to shear buckling before yielding*

When the flanges are plastic, compact or semi-compact but the web is susceptible to shear buckling before yielding (*see* 15.4.2.1), the design bending strength shall be calculated using one of the following methods:

a) the bending moment and axial force acting on the section may be assumed to be resisted by flanges only and the web is designed only to resist shear (*see* 15.4); and

b) the bending moment and axial force acting on the section may be assumed to be resisted by the whole section. In such a case, the web shall be designed for combined shear and normal stresses using simple elastic theory in case of semi-compact webs and simple plastic theory in the case of compact and plastic webs.

15.2.1.2 When the factored design shear force does not exceed 0.6 V_{d}, where V_{d} is the design shear strength of the cross section (*see* 15.4), the design bending strength, M_{d} shall be taken as:

$$M_{\mathrm{d}} = \beta_{\mathrm{b}} Z_{\mathrm{p}} f_{\mathrm{y}} / \gamma_{\mathrm{m0}}$$

To avoid irreversible deformation under serviceability loads, M_{d} shall be less than 1.2 $Z_{\mathrm{e}} f_{\mathrm{y}} / \gamma_{\mathrm{m0}}$ in case of simply supported and cantilever beams and 1.5 $Z_{\mathrm{e}} f_{\mathrm{y}} / \gamma_{\mathrm{m0}}$ in all other cases. of;

where

β_{b} = 1.0 for plastic and compact sections;

β_{b} = $Z_{\mathrm{e}} / Z_{\mathrm{p}}$ for semi-compact sections;

f_y = yield stress of the material;

γ_{m0} = partial safety factor (*see* **12.4.1**); and

Z_p, Z_e = plastic and elastic section moduli of the cross section, respectively

15.2.1.3 When the design shear force (factored), V exceeds $0.6V_d$, where V_d is the design shear strength of the cross section (*see* **15.4**) the design bending strength, M_d shall be taken as:

$$M_d = M_{dv}$$

where

M_{dv} = design bending strength under high shear as defined in **16.2**.

15.2.1.4 *Holes in the tension zone*

a) The effect of holes in the tension flange, on the design bending strength need not be considered if:

$$(A_{nf}/A_{gf}) \geq (f_y/f_u)\,(\gamma_{m1}/\gamma_{m0})\,/\,0.9$$

where

A_{nf}/A_{gf} = ratio of net to gross area of the flange in tension;

f_y/f_u = ratio of yield and ultimate stress of the material; and

γ_{m1}/γ_{m0} = ratio of partial safety factors against ultimate to yield stress (*see* **12.4.1**).

When the A_{nf}/A_{gf} does not satisfy the above requirement, the reduced effective flange area, A_{ef} satisfying the above equation may be taken as the effective flange area in tension, instead of A_{gf}.

b) The effect of holes in the tension region of the web on the design flexural strength need not be considered, if the limit given in **15.2.1.4**(a) above is satisfied for the complete tension zone of the cross section, comprising the tension flange and tension region of the web; and

c) Fastener holes in the compression zone of the cross section need not be considered in design bending strength calculation, except for oversize and slotted holes or holes without any fastener.

15.2.1.5 *Shear lag effects*

The shear lag effects in flanges may be disregarded provided:

a) For outstand elements (supported along one edge), $b_o \leq L_o / 20$; and

b) For internal elements (supported along two edges), $b_i \leq L_o / 10$.

where

b_o = width of the flange with outstand;

b_i = width of the flange as an internal element; and

L_o = length between points of zero moment (inflection) in the span.

Where these limits are exceeded, the effective width of flange for design strength may be calculated using specialist literature, or conservatively taken as the value satisfying the limit given above.

15.2.2 *Laterally Unsupported Beams*

Resistance to lateral torsional buckling need not be checked separately (member may be treated as laterally supported, *see* **15.2.1**) in the following cases:

a) bending is about the minor axis of the section;

b) section is hollow (rectangular/ tubular) or solid bars; and

c) in case of major axis bending, λ_{LT} (as defined herein) is less than 0.4.

The design bending strength of laterally unsupported beam as governed by lateral torsional buckling is given by:

$$M_d = \beta_b Z_p f_{bd}$$

where

β_b = 1.0 for plastic and compact sections;

= Z_e/Z_p for semi-compact sections (Class 3);

= Z_{eff}/Z_p for slender sections (Class 4);

f_{bd} = $\chi_{LT} f_y / \gamma_{m0}$;

= design bending compressive stress;

f_m = the moment gradient effect parameter given in the Table 14;

χ_{LT} = bending stress reduction factor to account for lateral torsional buckling, in doubly symmetrical sections with lateral support at the ends given by;

$$= \frac{f_m}{\left\{\varphi_{LT} + \left[\varphi_{LT}^2 - f_m \lambda_{LT}^2\right]^{0.5}\right\}} \leq 1.0 \;;$$

Z_p, Z_e, Z_{eff} = plastic section modulus and elastic section modulus (Class 3) and effective section modulus (class 4) with respect to extreme compression fibre;

α_{LT} = the imperfection parameter is given in Table 13; and

$$\varphi_{LT} = 0.5\left[1 + f_m\left(\left(\frac{\lambda_{LT}}{\lambda_y}\right)^2 \alpha_{LT}\left(\lambda_y - 0.2\right) + \lambda_{LT}^2\right)\right];$$

The non-dimensional slenderness ratio, λ_{LT}, is given by:

$$\lambda_{LT} = \sqrt{\beta_b Z_p f_y / M_{crLT}} \leq \sqrt{1.2 Z_e f_y / M_{crLT}} = \sqrt{f_y / f_{crLT}} \qquad \lambda_y = \sqrt{f_y / f_{cry}}$$

where

f_{cry} = the non-dimensional weak axis slenderness ratio for laterally supported length equal to distance between lateral supports to the compression flange;

f_{crLT} = extreme fibre bending compressive stress corresponding to elastic lateral torsional buckling moment (*see* **15.2.2.1**); and

M_{crLT} = elastic lateral torsional buckling moment calculated in accordance with **15.2.2.1**.

Table 13 Imperfection Parameter, α_{LT} for Lateral Torsional Buckling of Beams

(*Clause* 15.2.2)

Cross Section	Limits		α_{LT}
Rolled I or H Sections 	$h/b>1.2$	$t_f \leq 40$ mm	$0.12\sqrt{\frac{Z_{ez}}{Z_{ey}}} \leq 0.34$
		$t_f > 40$ mm	$0.16\sqrt{\frac{Z_{ez}}{Z_{ey}}} \leq 0.49$
	$h/b \leq 1.2$	—	$0.16\sqrt{\frac{Z_{ez}}{Z_{ey}}} \leq 0.49$
Welded I Sections 	$t_f \leq 40$ mm		$0.21\sqrt{\frac{Z_{ez}}{Z_{ey}}} \leq 0.64$
	$t_f > 40$ mm		$0.25\sqrt{\frac{Z_{ez}}{Z_{ey}}} \leq 0.76$
Rolled unequal I or H Sections 	$h/b_{min} \leq 2.0$		0.21
	$h/b_{min} > 2.0$		0.34
Welded unequal I section 	$h/b_{min} \leq 2.0$		0.64
	$h/b_{min} > 2.0$		0.76
Other rolled Sections 	-------		0.76

NOTE — The selection of lateral torsional buckling imperfection factor is based on b_{min} irrespective of it being tension or compression flange.

Table 14 Moment Gradient Effect Parameter

(*Clauses* 15.2.2 *and* 15.2.2.2)

Load Case	**Factor f_M (*Clause* 15.2.2)**	**Factor k_c (Clause 15.2)**
(1)	(2)	(3)
	1.0	1.0
	$1.25 - 0.1\psi - 0.15\ \psi^2$	$\dfrac{1}{1.33 - 0.33\ \psi}$
	1.05	0.94
	For $0 \le \frac{M_0}{M_h} < 2.0$: $1.0 + 1.35\ \frac{M_0}{M_h} - 0.33\ \left[\frac{M_0}{M_h}\right]^3$ For $\frac{M_0}{M_h} \ge 2.0$: 1.05	$\frac{M_0}{M_h} < 1.0 : 1.0$ $\frac{M_0}{M_h} \ge 1.0 : 0.9$
	For $0 \le \frac{M_0}{M_h} < 1.47$: $1.25 + 0.5\ \left[\frac{M_0}{M_h}\right]^2 - 0..275\ \left[\frac{M_0}{M_h}\right]^4$ For $\frac{M_0}{M_h} \ge 1.47$: 1.05	$\frac{M_0}{M_h} < 0.5 : 0.75$ $\frac{M_0}{M_h} \ge 0.5 : 0.91$
	1.10	0.86
	For $0 \le \frac{M_0}{M_h} < 2.0$: $1.0 + 1.25\ \frac{M_0}{M_h} - 0.30\ \left[\frac{M_0}{M_h}\right]^3$ For $\frac{M_0}{M_h} \ge 2.0$: 1.10	$\frac{M_0}{M_h} < 1.0 : 1.0$ $\frac{M_0}{M_h} \ge 1.0 : 0.77$
	For $0 \le \frac{M_0}{M_h} < 1.5$: $1.25 + 0.325\ \left[\frac{M_0}{M_h}\right]^2 - 0.175\ \left[\frac{M_0}{M_h}\right]^4$ For $\frac{M_0}{M_h} \ge 1.50$: 1.10	$\frac{M_0}{M_h} < 0.5 : 0.75$ $\frac{M_0}{M_h} \ge 0.5 : 0.82$

Where

M_0 is the bending moment at midspan, and may be determined by subtracting the average of the tow hogging end moments, form the midspan sagging moment for simply supported boundary condition.

For $\frac{M_0}{M_h} < 0.0$, f_m and k_c may be conservatively taken as 1.0.

15.2.2.1 *Elastic lateral torsional buckling moment*

In case of simply supported, prismatic members with doubly symmetric cross section subjected to uniform moment, the elastic lateral torsional buckling moment, M_{crLT}, can be determined from:

$$M_{\mathrm{crLT}} = \sqrt{\left\{\left(\frac{\pi^2 E I_y}{(L_{\mathrm{LT}})^2}\right)\left(G\, I_t + \frac{\pi^2 E\, I_w}{(L_{\mathrm{LT}})^2}\right)\right\}}$$

where

L_{LT} = effective lateral unbraced length for lateral torsional buckling (*see* **15.3**);

I_t = torsional constant $= \sum b_i t_i^3 / 3$ for open section;

I_w = warping constant; and

I_y = moment of inertia about the weaker, (y), axis.

M_{cr} for different beam sections, considering loading, support condition, and asymmetric section, shall be more accurately calculated using the method given in Annex E. The above equations for calculating M_{cr} may be conservatively used for channel sections.

15.2.2.2 *Simplified method for lateral torsional buckling*

A simplified method based on effective compression flange lateral buckling as given below may be used for monosymmetric and doubly symmetric I and H sections with and without lateral restraints, to determine the equivalent compression flange lateral buckling stress reduction factor, χ_{LTc},, that is substituted in equation given in **15.2.2** for calculating the design bending strength, M_d,

The stress reduction factor for lateral buckling of equivalent compression flange, χ_{LTc}, is evaluated using equations given in **14.1.2.1** for compression members, by treating the equivalent compression flange as a strut and substituting equivalent non-dimensional slenderness , λ_{LTc},, in the place of λ.

where

$$\lambda_{\mathrm{LTc}} = k_c \beta_c \lambda_{c,z}$$

k_c is a slenderness correction factor for moment gradient between restraints, as given in Table 14.

$$\beta_c = \sqrt{\frac{0.06\,\frac{h}{t_{f,\max}}}{\lambda_{c,z} + \frac{t_{f,\max}}{t_{f,\min}}}}$$

$t_{f,\max}$ is the maximum thickness of the top and bottom flange of the section

$t_{f,\min}$ is the minimum thickness of the top and bottom flange of the section

$$\lambda_{c,z} = \sqrt{\frac{f_y}{f_{cr,cz}}}$$

where

A_c = is the area of equivalent compression flange, given by;

A_c = $A_{cf}+A_w/2$ for load applied at compression flange;

A_c = $A_{cf}+A_w/6$ for load applied at shear centre of the beam section;

A_c = A_{cf} for load applied at tension flange;

A_{cf} = is the area of compression flange (= b_c t_{fc});

A_w = is the area of the web (=h t_w); and

$f_{cr,cz}$ = is the elastic critical axial stress of the equivalent compression flange of area of the baeam, A_c, as given below, buckling about the centre line axis of the web as a strut.

15.3 Effective Length for Lateral Torsional Buckling

15.3.1 For simply supported beams and girders of span length, L, where no lateral restraint to the compression flanges is provided, but where each end of the beam is restrained against torsion, the effective length L_{LT} of the lateral buckling to be used in **15.2.2.1** shall be taken as in Table 15.

In simply supported beams with intermediate lateral restraints against lateral torsional buckling, the effective length for lateral torsional buckling, L_{LT} to be used in **15.2.2.1**, may be conservatively taken as the length of the relevant segment in between the lateral restraints, or can be calculated using other known methods or rigorous analysis**.** In the case of intermediate partial lateral restraints, the effective length, L_{LT} shall be taken as equal to 1.2 times the length of the relevant segment in between the partial lateral restraints.

Restraint against torsional rotation at supports in these beams may be provided by:

a) web or flange cleats; or

b) bearing stiffeners acting in conjunction with the bearing of the beam; or

c) lateral end frames or external supports providing lateral restraint to the compression flanges at the ends; or

d) their being built into walls.

Table 15 Effective Length for Simply Supported Beams, L_{LT}

(*Clause* 15.3.1)

Sl No.	Conditions of Restraint at Supports		Loading Condition	
	Torsional Restraint	Warping Restraint	Normal	Destabilizing
(1)	(2)	(3)	(4)	(5)
i)	Fully restrained	Both flanges fully restrained	0.70 L	0.85 L
ii)	Fully restrained	Only compression flange fully restrained	0.75 L	0.90 L
iii)	Fully restrained	Both flanges partially restrained	0.80 L	0.95 L
iv)	Fully restrained	Only compression flange partially restrained	0.85 L	1.00 L
v)	Fully restrained	No restraint in both flanges	1.00 L	1.20 L
vi)	Partially restrained by bottom flange support connection	No restraint in both flanges	1.0 L+ 2D	1.2 L+2D
vii)	Partially restrained by bottom flange bearing support	No restraint in both flanges	1.2 L+2D	1.4 L+2D

NOTES

1 Torsional restraint prevents rotation about the longitudinal axis.

2 Warping restraint prevents rotation of the flange in its plane.

3 D is the overall depth of the beam.

4 In case of continuous beams, L shall be taken as the distance between points of inflection, and the restraint conditions at the point of inflections should be considered.

15.3.2 For beams, which are provided with members giving effective lateral restraint to the compression flange at intervals along the span, in addition to the end torsional restraint required in **15.3.1**, the effective length for lateral torsional buckling shall be taken as the distance, centre-to-centre of the restraint members in the critical segment under normal loading condition and 1.2 times this distance, where the load is acting on the beam above the shear centre and towards the shear centre, so as to have greater destabilizing effect during lateral torsional buckling deformation.

15.3.3 For cantilever beams of projecting length L, the effective length L_{LT} to be used in **15.2.2.1** shall be taken as in Table 16 for different support conditions.

15.3.4 Where a member is provided intermediate lateral supports to improve the lateral buckling strength, these restraints should have sufficient strength and stiffness to prevent lateral movement of the compression flange at that point, relative to the end supports. The intermediate lateral restraints should be either connected to an appropriate bracing system capable of transferring the restraint force to the effective lateral support at the ends of the member, or should be connected to an independent robust part of the structure capable of transferring the restraint force. Two or more parallel member requiring such lateral restraint shall not be simply connected together assuming mutual dependence for the lateral restraint.

The intermediate lateral restraints should be connected to the member as close to the compression flange as practicable. Such restraints should be closer to the shear centre of the compression flange than to the shear centre of the section. However, if torsional restraint preventing relative rotation between the two flanges is provided, the intermediate lateral restraint may be connected at any appropriate level. The point of contraflexure in beams with double curvature should be additionally effectively restrained against torsion in order to be considered it as a brace location.

For beams which are provided with members giving effective lateral restraint at intervals along the span, the effective lateral restraint shall be capable of resisting a force of 2.5 percent of the maximum force in the compression flange taken as divided equally between the points at which the restraint members are provided. Further, each restraint point should be capable of resisting 1 percent of the maximum force in the compression flange.

15.3.4.1 In a series of such beams, with solid webs, which are connected together by the same system of restraint members, the sum of the restraining forces required shall be taken as 2.5 percent of the maximum flange force in one beam only.

15.3.4.2 In the case of a series of latticed beams, girders or roof trusses which are connected together by the same system of restraint members, the sum of the restraining forces required shall be taken as 2.5 percent of the maximum force in the compression flange plus 1.25 percent of this force for every member of the series other than the first, up to a maximum total of 7.5 percent.

15.3.5 Purlins adequately restrained by sheeting need not be normally checked for the restraining forces required by rafters, roof trusses or portal frames that carry predominately roof loads provided there is bracing of adequate stiffness in the plane of rafters or roof sheeting which is capable of acting as a stressed skin diaphragm.

15.3.6 In case of beams with double curvature bending, adequate direct lateral support to the compression flange in the hogging moment region may be provided as given above for simply supported beam. The effect of support to the tension (top) flange in the hogging moment region on lateral restraint to the compression flange may be considered as per specialist literature.

15.3.7 In case of cantilever beams with tip loading, at the free end the tension flange also shall be effectively braced against lateral movement.

15.4 Shear

The design of plated webs with and without stiffeners are treated in this section. The design recommendations of Corrugated plate girders are presented in Annex G.

The factored design shear force, V, in a beam due to external actions shall satisfy:

$$V \leq V_{\mathrm{d}}$$

where

V_d = design strength

= V_n / γ_{m0}

where

γ_{m0} = partial safety factor against shear failure (*see* **12.4.1**)

The nominal shear strength of a cross section, V_n, may be governed by plastic shear resistance (*see* **15.4.1**) or strength of the web as governed by shear buckling (*see* **15.4.2**).

15.4.1 The nominal plastic shear resistance under pure shear is given by:

$$V_n = V_p$$

where

$$V_p = \frac{A_v f_{yw}}{\sqrt{3}}$$

A_v = shear area; and

f_{yw} = yield strength of the web.

15.4.1.1 The shear area may be calculated as given below:

a) I-and channel sections:

1) *Major Axis Bending*:

Hot-rolled : $h\, t_w$

Welded : $d\, t_w$

2) *Minor Axis Bending*:

Hot-rolled or welded : $2b\, t_f$

b) Rectangular hollow sections of uniform thickness:

Loaded parallel to depth (h) : $A\, h / (b+h)$

Loaded parallel to width (b) : $A\, b / (b+h)$

c) Circular hollow tubes of uniform thickness : $2A / \pi$

d) Plates and solid bars : A

where

A = cross section area;

b = overall breadth of tubular section, breadth of I-section flanges;

d = clear depth of the web between flanges;

h = overall depth of the section;

t_f = thickness of the flange; and

t_w = thickness of the web.

NOTE — Fastener holes need not be accounted for in plastic design shear strength calculation provided that:

$$A_{vn} \geq (f_y / f_u)(\gamma_{m1} / \gamma_{m0})\, A_v / 0.9$$

If A_{vn} does not satisfy the above condition, the effective shear area may be taken as that satisfying the above limit. Block shear failure criteria may be verified at the end connections. Provisions given under **16** may be referred to for design strength under combined high shear and bending.

15.4.2 *Resistance to Shear Buckling*

15.4.2.1 Resistance to shear buckling shall be verified as specified, when

$d/t_w > 67\varepsilon_w$ for a web without stiffeners, and

$> 67\varepsilon_w \sqrt{\frac{K_v}{5.35}}$ for a web with stiffeners

where

K_v = shear buckling coefficient (*see* **15.4.2.2**); and

$\varepsilon_w = \sqrt{250 / f_{yw}}$

15.4.2.2 *Shear buckling design methods*

The nominal shear strength, V_n, of webs with or without intermediate stiffeners as governed by buckling may be evaluated using one of the following methods:

a) *Simple post-critical method* — The simple post critical method, based on the shear buckling strength can be used for webs of I-section girders, with or without intermediate transverse stiffener, provided that the web has transverse stiffeners at the supports. The nominal shear strength is given by:

$$V_n = V_{cr}$$

where

V_{cr} = shear force corresponding to web buckling; and

= $A_v\tau_b$

where

τ_b = shear stress corresponding to web buckling, determined as follows:

1) when $\lambda_w \leq 0.8$, $\tau_b = f_{yw}/\sqrt{3}$
2) when $0.8 < \lambda_w < 1.2$, $\tau_b = [1-0.8(\lambda_w - 0.8)](f_{yw}/\sqrt{3})$
3) when $\lambda_w \geq 1.2$, $\tau_b = f_{yw}/\left(\sqrt{3}\,\lambda_w^{\;2}\right)$

where

λ_w = Non -dimensional web slenderness ratio for shear buckling stress, given by:

$$\lambda_w = \sqrt{f_{yw}/(\sqrt{3}\,\tau_{cr,e})}$$

$\tau_{cr,e}$ = the elastic critical shear stress of the web = $\dfrac{K_v \pi^2 E}{12\left(1-\mu^2\right)\left[d/t_w\right]^2}$

where

μ = Poisson’s ratio; and

K_v = 5.35 when transverse stiffeners are provided only at supports

= $4.0 + 5.35/(c/d)^2$ for $c/d < 1.0$

= $5.35 + 4.0/(c/d)^2$ for $c/d \geq 1.0$

where c, d are the spacing of transverse stiffeners and depth of the web, respectively.

b) *Tension field method* — The tension field method, based on the post-shear buckling strength, may be used for webs with intermediate transverse stiffeners, in addition to the transverse stiffeners at supports, provided the panels adjacent to the panel under tension field action, or the end posts provide anchorage for the tension fields and if $c/d \geq 1.0$, where c, d are the spacing of transverse stiffeners and depth of the web, respectively.

In the tension field method, the nominal shear resistance, V_n, is given by:

$$V_n = V_{tf}$$

where

$$V_{tf} = [A_v \tau_b + 0.9\, w_{tf} t_w f_v \sin\phi] \leq V_p$$

where

τ_b = shear stress corresponding to buckling of web **15.4.2.2**(a);

f_v = yield strength of the tension field obtained from $\left[f_{yw}^2 - 3\tau_b^2 + \psi^2\right]^{0.5} - \psi$;

ψ = $1.5\,\tau_b \sin 2\phi$;

ϕ = inclination of the tension field nearly $= \tan^{-1}\dfrac{\left(\dfrac{d}{c}\right)}{1.5}$;

w_{tf} = width of the tension field, given by:

= $d\cos\phi - (c - s_c - s_t)\sin\phi$;

f_{yw} = yield stress of the web;

d = depth of the web;

c = spacing of transverse stiffeners in the web; and

s_c, s_t = anchorage lengths of tension field along the compression and tension flange respectively, obtained from:

$$s = \frac{2}{\sin\phi}\left[\frac{M_{fr}}{f_{yw} t_w}\right]^{0.5} \leq c$$

M_{fr} = reduced plastic moment capacity of the respective flange plate (disregarding any edge stiffener) after accounting for the axial force, N_f in the flange, due to overall bending and any external axial force in the cross section, and is calculated as :

$$M_{fr} = 0.25 b_f t_f^2 f_{yf}\left[1 - \left\{N_f / \left(b_f t_f f_{yf}/\gamma_{m0}\right)\right\}^2\right]$$

b_f, t_f = width and thickness of the relevant flange respectively; and

f_{yf} = yield stress of the flange.

15.5 Stiffened Web Panels

15.5.1 *End Panels Design* (*see* Fig.12)

The girders in which the interior panel (panel A) is designed using tension field action, the end panels shall be designed using only simple post critical method, according to **15.4.2.2**(a).

Additionally, the end panel along with the stiffeners should be checked as a beam spanning between the flanges to resist a shear force, $R_{tf,}$ and a moment, $M_{tf,}$ due to tension field forces as given in **15.5.3**. Further, end stiffener should be capable of resisting the reaction plus a compressive force due to the moment, equal to M_{tf} [*see* Fig. (12)].

15.5.2 *End Panels Designed Using Tension Field Action* (*see* Fig. 13 and Fig. 14)

The end panel (Panel A) shall be designed according to **15.4.2.2**(b).

Additionally, it should be provided with an end post consisting of a single or double stiffener, (*see* Fig. 13 and Fig. 14), satisfying the following.

a) *Single stiffener* (*see* Fig. 13) — The top of the end post should be rigidly connected to the flange using full strength welds.

The end post should be capable of resisting the reaction plus a moment from the anchor forces equal to 2/3 M_{tf} due to tension field forces, where M_{tf} is obtained from **15.5.3**. The width and thickness of the end post are not to exceed the width and thickness of the flange.

b) *Double stiffener* (*see* Fig. 14) —The end post should be checked as a beam spanning between the flanges of the girder and capable of resisting a shear force R_{tf} and a moment, M_{tf} due to the tension field forces as given in **15.5.3**.

15.5.3 *Anchor Forces*

The resultant longitudinal shear, R_{tf}, and a moment M_{tf} from the anchor of tension field forces are evaluated as given below:

$$R_{tf} = \frac{H_q}{2} \text{ and } M_{tf} = \frac{H_q d}{10}$$

where

$$H_q = 1.25V_p\left(1 - \frac{V_{cr}}{V_p}\right)^{1/2}$$

$$V_p = \frac{dtf_y}{\sqrt{3}}$$

d = web depth,

If the actual factored shear force, V in the panel designed using tension field approach is less than the shear strength, V_{tf} as given in **15.4.2.2**(b), then the values of H_q may be reduced by the ratio $\frac{V - V_{cr}}{V_{tf} - V_{cr}}$

where

V_{cr} = critical shear strength for the panel designed utilizing tension field action as given in **15.4.2.2**(a); and

V_{tf} = basic shear strength for the panel utilizing tension field action as given in **15.4.2.2**(b).

NOTES

1 Panel A is designed utilizing tension field action as given in 15.4.2.2(b).

2 Bearing stiffener is designed for compressive force due to bearing as given in 15.4.2.2(a).

3 End post is designed for horizontal shear R_{tf} and moment M_{tf} as given in 15.5.3.

15.5.4 *Panels with Openings* — Panels with opening of dimension greater than 10 percent of the minimum panel dimension should be designed without using tension field action as given in 15.4.2.2(b). The adjacent panels should be designed as an end panel as given in 15.5.1 or 15.5.2, as appropriate.

15.6 Design of Beams and Plate Girders with Solid Webs

15.6.1 *Minimum Web Thickness*

The thickness of the web in a section shall satisfy the requirements given in 15.6.1.1 and 15.6.1.2.

15.6.1.1 *Serviceability requirement*

a) when transverse stiffeners are not provided:

   1) $\frac{d}{t_w} \leq 200\varepsilon_w$ (web connected to flanges along both longitudinal edges); and

   2) $\frac{d}{t_w} \leq 90\varepsilon_w$ (web connected to flanges along one longitudinal edge only).

b) when only transverse stiffeners are provided (in webs connected to flanges along both longitudinal edges):

   1) when $3d \geq c \geq d$

   $\frac{d}{t_w} \leq 200\varepsilon_w$;

   2) when $0.74\,d \leq c < d$

   $\frac{c}{t_w} \leq 200\varepsilon_w$;

   3) when $c < 0.74d$

   $\frac{d}{t_w} \leq 270\varepsilon_w$; and

   4) when $c > 3d$, the web shall be considered as unstiffened.

c) when transverse stiffeners and longitudinal stiffeners at one level only are provided (distance from the compression flange equal to 2/5 of the distance from the compression flange angle, plate or tongue plate to the neutral axis) according to 15.7.13(a):

   1) when $2.4d \geq c \geq d$

   $\frac{d}{t_w} \leq 250\varepsilon_w$

   2) when $0.74\,d \leq c \leq d$

   $\frac{c}{t_w} \leq 250\varepsilon_w$

   3) when $c < 0.74\,d$

   $\frac{d}{t_w} \leq 340\varepsilon_w$

d) when a second longitudinal stiffener (located at neutral axis is provided) $\frac{d}{t_w} \leq 400\varepsilon_w$

where

c = spacing of transverse stiffener (*see* Fig. 12 and Fig. 13);

d = depth of the web;

f_{yw} = yield stress of the web;

t_w = thickness of the web; and

ε_w = yield stress ratio of web = $\sqrt{250/f_{yw}}$.

15.6.1.2 *Compression flange buckling requirement*

In order to avoid buckling of the compression flange into the web, the web thickness shall satisfy the following:

a) When transverse stiffeners are not provided;

$$\frac{d}{t_w} \leq 345\varepsilon_f^2$$

b) When transverse stiffeners are provided, and

1) when $c \geq 1.5\ d$

$$\frac{d}{t_w} \leq 345\varepsilon_f^2$$

2) when $c < 1.5d$

$$\frac{d}{t_w} \leq 345\varepsilon_f$$

where

c = spacing of transverse stiffener (*see* Fig. 12 and Fig. 13);

d = depth of the web;

f_{yf} = yield stress of compression flange;

t_w = thickness of the web; and

ε_f = yield stress ratio of flange = $\sqrt{250/f_{yf}}$.

15.6.2 *Sectional Properties*

The effective sectional area of compression flanges shall be the gross area with deductions for excessive width of plates as specified for compression members [*see* **14**] and for open holes occurring in a plane perpendicular to the direction of stress at the section being considered (*see* **15.2.1.4**).

The effective sectional area of tension flanges shall be the gross sectional area with deductions for holes as specified in **15.2.1.4**.

The effective sectional area for parts in shear shall be taken as specified in **15.4.1.1**.

15.6.3 *Flanges*

15.6.3.1 In riveted or bolted construction, flange angles shall form as large a part of the area of the flange as practicable (preferably not less than one-third) and the number of flange plates shall be kept to a minimum.

In exposed situations, where flange angles are used, at least one plate of the top flange shall extend over the full length of the girder, unless the top edge of the web is machined flush with the flange angles. Where two or more flange plates are used, tacking rivets shall be provided, if necessary to comply with the requirements of **17**.

Each flange plate shall extend beyond its theoretical cut-off point, and the extension shall contain sufficient rivets, bolts or welds to develop in the plate, the load calculated for the bending moment on the girder section (taken to include the curtailed plate) at the theoretical cut-off point.

The outstand of flange plates, that is the projection beyond the outer line of connections to flange angles, channel or joist flanges or in the case of welded constructions their projection beyond the face of the web or tongue plate, shall not exceed the values given in **10.8.2** (*see* Table 2).

In the case of box girders, the thickness of any plate, or the aggregate thickness of two or more plates, when these plates are tacked together to form the flange, shall satisfy the requirements given in **10.8.2** (*see* Table 2).

15.6.3.2 *Flange splices*

Flange splices should preferably, not be located at points of maximum stress. Where splice plates are used, their area shall be not less than 5 percent in excess of the area of the flange element spliced; their centre of gravity shall coincide, as nearly as possible, with that of the element spliced. There shall be enough bolts, rivets or welds on each side of the splice to develop the load in the element spliced plus 5 percent but in no case should the strength developed be less than 50 percent of the effective strength of the material spliced. In welded construction, flange plates shall be joined by complete penetration butt welds, wherever possible. These butt welds shall develop the full strength of the plates.

15.6.3.3 *Connection of flanges to web*

The flanges of plate girders shall be connected to the web by sufficient rivets, bolts or welds to transmit the maximum horizontal shear force resulting from the bending moment gradient in the girder, combined with any vertical loads which are directly applied to the flange. If the web is designed using tension field method as given in **15.4.2.2** (b), the weld should be able to transfer the tension field stress, f_{yw} acting on the web.

15.6.3.4 *Bolted/Riveted construction*

For girders in exposed situations and which do not have flange plates for their entire length, the top edge of the web plate shall be flush with or above the angles, and the bottom edge of the web plate shall be flush with or set back from the angles.

15.6.3.5 *Welded construction*

The gap between the web plates and flange plates shall be kept to a minimum and for fillet welds shall not exceed 1 mm at any point before welding.

15.6.4 *Webs*

15.6.4.1 *Effective sectional area of web of plate girder*

The effective cross sectional area shall be taken as the full depth of the web plate multiplied by the thickness.

NOTE — Where webs are varied in thickness in the depth of the section by the use of tongue plates or the like, or where the proportion of the web included in the flange area is 25 percent or more of the overall depth, the above approximation is not permissible and the maximum shear stress shall be computed on theory.

15.6.4.2 *Splices in webs*

Splices and cutouts for service ducts in the webs should preferably not be located at points of maximum shear force and heavy concentrated loads.

Splices in the webs of the plate girders and rolled sections shall be designed to resist the shears and moments at the spliced section (*see* Annex F).

In riveted or bolted construction, splice plates shall be provided on each side of the web. In welded construction, web splices shall preferably be made with complete penetration butt welds.

15.6.4.3 Where additional plates are required to augment the strength of the web, they shall be placed on each side of the web and shall be equal in thickness. The proportion of shear force assumed to be resisted by these plates shall be limited by the amount of horizontal shear which they can transmit to the flanges through their fastenings, and such reinforcing plates and their fastenings shall be carried up to the points at which the flange without the additional plates is adequate.

15.7 Stiffener Design

15.7.1 *General*

15.7.1.1 When the web of a member acting alone (that is, without stiffeners) proves inadequate, stiffeners for meeting the following requirements should be provided:

a) *Intermediate transverse web stiffener* — To improve the buckling strength of a slender web due to shear (*see* **15.7.2**).

b) *Load carrying stiffener* — To prevent local buckling of the web due to concentrated loading (*see* **15.7.3** and **15.7.5**).

c) *Bearing stiffener* — To prevent local crushing of the web due to concentrated loading (*see* **15.7.4** and **15.7.6**).

d) *Torsion stiffener* — To provide torsional restraint to beams and girders at supports (*see* **15.7.9**).

e) *Diagonal stiffener* — To provide local reinforcement to a web under shear and bearing (*see* **15.7.7**).

f) *Tension stiffener* — To transmit tensile forces applied to a web through a flange (*see* **15.7.8**).

The same stiffeners may perform more than one function and their design should comply with the requirements of all the functions for which designed.

15.7.1.2 *Outstand of web stiffeners*

Unless the outer edge is continuously stiffened, the outstand from the face of the web should not exceed $20t_q\varepsilon$.

When the outstand of web stiffener is between $14t_q\varepsilon$ and $20t_q\varepsilon$, then the stiffener design should be on the basis of a core section with an outstand of only $14t_q\varepsilon$, where t_q is the thickness of the stiffener.

15.7.1.3 *Stiff bearing length*

The stiff bearing length of any element, b_1, is that length which cannot deform appreciably in bending. To determine b_1, the dispersion of load through a steel bearing element should be taken as 45° through solid material, such as bearing plates, flange plates, etc (*see* Fig.15).

15.7.1.4 *Eccentricity*

Where a load or reaction is applied eccentric to the centreline of the web or where the centroid of the stiffener does not lie on the centreline of the web, the resulting eccentricity of loading should be accounted for in the design of the stiffener.

15.7.1.5 *Buckling resistance of stiffeners*

The buckling resistance F_{qd} should be based on the design compressive stress f_{cd} (*see* **14.1.2**) of a strut (curve c), the radius of gyration being taken about the axis parallel to the web. The effective section is the full area or core area of the stiffener (*see* **15.7.1.2**) together with an effective length of web on each side of the centreline of the stiffeners, limited to 20 times the web thickness. The design strength used should be the minimum value obtained for buckling about the web or the stiffener.

The effective length for intermediate transverse stiffeners used in calculating the buckling resistance, F_{qd}, should be taken as 0.7 times the length, L of the stiffener.

The effective length for load carrying web stiffeners used in calculating the buckling resistance, F_{xd}, assumes that the flange through which the load or reaction is applied is effectively restrained against lateral movement relative to the other flange, the effective length should be taken as:

a) $KL = 0.7L$, when flange is restrained against rotation in the plane of the stiffener (by other structural elements); and

b) $KL = L$, when flange is not so restrained.

where

L = length of the stiffener.

If the load or reaction is applied to the flange by a compression member, then unless effective lateral restraint is provided at that point, the stiffener should be designed as part of the compression member applying the load, and the connection between the column and beam flange shall be checked for the effects of the strut action.

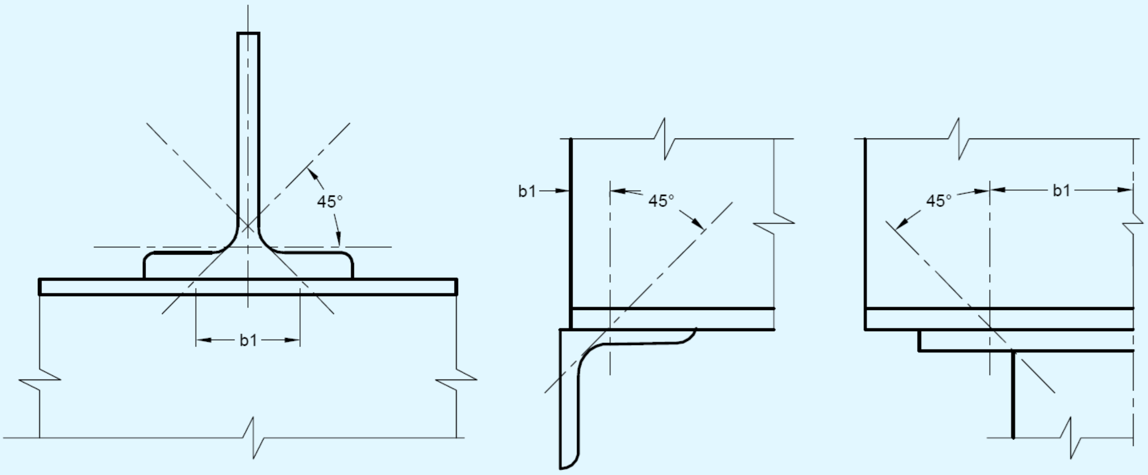

FIG. 15 STIFF BEARING LENGTH, B1

15.7.2 *Design of Intermediate Transverse Web Stiffeners*

15.7.2.1 *General*

Intermediate transverse stiffeners may be provided on one or both sides of the web.

15.7.2.2 *Spacing*

Spacing of intermediate stiffeners, where provided, shall comply with 15.6.1 depending on the thickness of the web.

15.7.2.3 *Outstand of stiffeners*

The outstand of the stiffeners should comply with 15.7.1.2.

15.7.2.4 *Minimum stiffeners*

Transverse web stiffeners not subject to external loads or moments should have a second moment of area, I_s about the centreline of the web, if stiffeners are on both sides of the web and about the face of the web, if single stiffener on only one side of the web is used such that:

if $c/d \geq \sqrt{2}$, $I_s \geq 0.75\, d\, t_w^3$, and

if $c/d < \sqrt{2}$, $I_s \geq \dfrac{1.5\, d^3 t_w^3}{c^2}$

where

c = actual stiffener spacing;

d = depth of the web; and

t_w = minimum required web thickness for spacing using tension field action, as given in **15.4.2.1**.

15.7.2.5 *Buckling check on intermediate transverse web stiffeners*

Stiffeners not subjected to external loads or moments should be checked for a stiffener force:

$$F_q = V - V_{cr} / \gamma_{m0} \leq F_{qd}$$

where

F_{qd} = design resistance of the intermediate stiffeners;

V_{cr} = shear buckling resistance of the web panel designed without using tension field action as given in **15.4.2.2 (a)**; and

V = factored shear force adjacent to the stiffener.

Stiffeners subject to external loads and moments should meet the conditions for load carrying web stiffeners in **15.7.3**. In addition they should satisfy the following interaction expression:

$$\frac{F_q - F_x}{F_{qd}} + \frac{F_x}{F_{xd}} + \frac{M_q}{M_{yq}} \leq 1$$

where

F_q = stiffener force given above;

F_{qd} = design resistance of an intermediate web stiffener corresponding to buckling about an axis parallel to the web (*see* **15.7.1.5**);

F_x = external load or reaction at the stiffener;

F_{xd} = design resistance of a load carrying stiffener corresponding to buckling about axis parallel to the web (*see* **15.7.1.5**);

M_q = moment on the stiffener due to eccentrically applied load and transverse load, if any; and

M_{yq} = yield moment capacity of the stiffener based on its elastic modulus about its centroidal axis parallel to the web.

If $F_q < F_x$, then $(F_q - F_x)$ should be taken as zero;

15.7.2.6 *Connection of intermediate stiffeners to web*

Intermediate transverse stiffeners not subject to external loading should be connected to the web so as to withstand a shear between each component of the stiffener and the web (in kN/mm) of not less than:

$$t_w^2 / (5 b_s)$$

where

t_w = web thickness, in mm; and

b_s = outstand width of the stiffener, in mm.

For stiffeners subject to external loading, the shear between the web and the stiffener due to such loading has to be added to the above value.

Stiffeners not subject to external loads or moments may terminate clear of the tension flange and in such a situation the distance cut short from the line of the weld should not be more than $4t_w$.

15.7.3 *Load Carrying Stiffeners*

15.7.3.1 *Web check*

Load carrying web stiffeners should be provided where compressive forces applied through a flange by loads or reactions exceed the buckling strength, F_{cdw}, of the unstiffened web, calculated using the following:

The effective length of the web for evaluating the slenderness ratio is calculated as in 15.7.1.5. The area of cross section is taken as $(b_1+n_1)\ t_w$.

where

b_1 = width of stiff bearing on the flange (*see* 15.7.1.3); and

n_1 = dispersion of the load through the web at 45°, to the level of half the depth of the cross-section.

The buckling strength of this web about axis parallel to the web is calculated as given in 14.1.2.1, using curve 'c'.

15.7.4 *Bearing Stiffeners*

Bearing stiffeners should be provided for webs where forces applied through a flange by loads or reactions exceeding the local capacity of the web at its connection to the flange, F_w, given by:

$$F_w = (b_1 + n_2) t_w f_{yw} / \gamma_{m0}$$

where

b_1 = Stiff bearing length (*see* 15.7.1.3);

n_2 = Length obtained by dispersion through the flange to the web junction at a slope of 1 : 2.5 to the plane of the flange;

t_w = Thickness of the web; and

f_{yw} = Yield stress of the web.

15.7.5 *Design of Load Carrying Stiffeners*

15.7.5.1 *Buckling check*

The external load or reaction, F_x on a stiffener should not exceed the buckling resistance, F_{xd} of the stiffener as given in 15.7.1.5.

Where the stiffener also acts as an intermediate stiffener it should be checked for the effect of combined loads in accordance with 15.7.2.5.

15.7.5.2 *Bearing check*

Load carrying web stiffeners should also be of sufficient size that the bearing strength of the stiffener, $F_{psd,}$ given below is not less than the load transferred, F_x

$$F_{psd} = A_q f_{yq} / (0.8\gamma_{m0}) \geq F_x$$

where

F_x = external load or reaction,

A_q = area of the stiffener in contact with the flange, and

f_{yq} = yield stress of the stiffener.

15.7.6 *Design of Bearing Stiffeners*

Bearing stiffeners should be designed for the applied load or reaction less the local capacity of the web as given in **15.7.4**. Where the web and the stiffener material are of different strengths the lesser value should be assumed to calculate the capacity of the web and the stiffener. Bearing stiffeners should project nearly as much as the overhang of the flange through which load is transferred.

15.7.7 *Design of Diagonal Stiffeners*

Diagonal stiffeners should be designed to carry the portion of the applied shear and bearing that exceeds the capacity of the web.

Where the web and the stiffener are of different strengths, the value for design should be taken as given in **15.7.6**.

15.7.8 *Design of Tension Stiffeners*

Tension stiffeners should be designed to carry the portion of the applied load or reaction less the capacity of the web as given in **15.7.4** for bearing stiffeners.

Where the web and the stiffener are of different strengths, the value for design should be taken as given in **15.7.6**.

15.7.9 *Torsional Stiffeners*

Where bearing stiffeners are required to provide torsional restraint at the supports of the beam, they should meet the following criteria:

a) Conditions of **15.7.4**; and

b) Second moment of area of the stiffener section about the centreline of the web, I_s should be such that:

$$I_s \geq 0.34\, \alpha_s\, D^3\, T_{cf}$$

where

α_s = 0.006 for $L_{LT} / r_y \leq 50$;

= $0.3/(L_{LT}/r_y)$ for $50 < L_{LT}/r_y \leq 100$;

= $30/(L_{LT}/r_y)^2$ for $L_{LT}/r_y > 100$;

D = Overall depth of beam at support;

T_{cf} = Maximum thickness of compression flange in the span under consideration;

L_{LT} = Laterally unsupported effective length of the compression flange of the beam; and

r_y = Radius of gyration of the beam about the minor axis.

15.7.10 *Connection to Web of Load Carrying and Bearing Stiffeners* — Stiffeners, which resist loads or reactions applied through a flange, should be connected to the web by sufficient welds or fasteners to transmit a design force equal to the lesser of:

a) tension capacity of the stiffener; and

b) sum of the forces applied at the two ends of the stiffener when they act in the same direction or the larger of the forces when they act in opposite directions.

Stiffeners, which do not extend right across the web, should be of such length that the shear stress in the web due to the design force transmitted by the stiffener does not exceed the shear strength of the web. In addition, the capacity of the web beyond the end of the stiffener should be sufficient to resist the applied force.

15.7.11 *Connection to Flanges*

15.7.11.1 *In tension*

Stiffeners required to resist tension should be connected to the flange transmitting the load by continuous welds or non-slip fasteners.

15.7.11.2 *In compression*

Stiffeners required to resist compression should either be fitted against the loaded flange or connected by continuous welds or non-slip fasteners.

The stiffener should be fitted against or connected to both flanges when:

a) a load is applied directly over a support; or

b) it forms the end stiffener of a stiffened web; or

c) it acts as a torsion stiffener.

15.7.12 *Hollow Sections*

Where concentrated loads are applied to hollow sections consideration should be given to local stresses and deformations and the section reinforced as necessary.

15.7.13 *Horizontal Stiffeners*

Where horizontal stiffeners are used in addition to vertical stiffeners, they shall be as follows:

a) One horizontal stiffener shall be placed on the web at a distance from the compression flange equal to 2/5 of web depth, d when the thickness of the web is less than the limits specified in **15.6.1**. The stiffener shall be designed so that I_s is not less than $4ct_w^3$ where I_s and t_w are as defined in **15.7.2.4** and c is the actual distance between the vertical stiffeners;

b) A second horizontal stiffener (single or double) shall be placed at the neutral axis of the girder when the thickness of the web is less than the limit specified in **15.6.1**. This stiffener shall be designed so that I_s is not less than $d_2\,t_w^3$ where I_s and t_w are as defined in **15.7.2.4** and d_2 is twice the clear distance from the compression flange angles, plates or tongue plates to the neutral axis;

c) Horizontal web stiffeners shall extend between vertical stiffeners, but need not be continuous over them; and

d) Horizontal stiffeners may be in pairs arranged on each side of the web, or single located on one side of the web.

15.8 Box Girders

The design and detailing of box girders shall be such as to give full advantage of its higher load carrying capacity. Box girder shall be designed in accordance with specialist literature. The diaphragms and horizontal stiffeners should conform to **15.7.12** and **15.7.13**.

15.8.1 All diaphragms shall be connected so as to transfer the resultant shears to the web and flanges.

15.8.2 Where the concentrated or moving load does not act directly on top of the web, the local effect shall be considered in the design of flanges and the diaphragms.

15.9 Purlins and Sheeting Rails (Girts)

All purlins shall be designed in accordance with the requirements for beams as specified in **15.2.1** and **15.2.2**. The limitations of bending stress based on lateral instability of the compression flange shall be considered if the purlin does not receive adequate support from bracings and sheathings in the plane of compression flange. In any case the maximum bending moment shall not exceed the values specified in **15.2.1**. The calculated deflections should not exceed those permitted for the type of roof cladding used, as specified in **12.6.1**. In calculating the bending moment, advantage may be taken of the continuity of the purlin over supports. The bending about the two axes shall be determined separately and checked according to the biaxial bending requirements specified under **16**.

15.10 Bending in a Non-Principal Plane

15.10.1 When the flexural deflection of a member is constrained to a non-principal plane by lateral restraints preventing lateral deflection, then the force exerted by the restraints shall be determined, and the principal axes bending moments acting on the member shall be calculated from these forces and applied forces, by a rational analysis. The combined effect of bending about the principal axes shall satisfy the requirements given under **16**.

15.10.2 When the deflections of a member loaded in a non-principal plane are unconstrained; the principal axes bending moments shall be calculated by a rational analysis. The combined effect of bending about the principal axes shall satisfy the requirements given under **16**.

16 MEMBER SUBJECTED TO COMBINED FORCES

16.1 General

This Section governs the design of members subjected to combined forces, such as shear force and bending, axial force and bending, or shear force, axial force and bending.

16.2 Combined Shear and Bending

16.2.1 No reduction in moment capacity of the section is necessary as long as the cross section is not subjected to high shear force (factored value of applied shear force is less than or equal to 60 percent of the shear strength of the section as given in **15.4**). The moment capacity may be taken as, M_d (*see* **15.2**) without any reduction.

16.2.2 When the factored value of the applied shear force is high (exceeds the limit specified in **16.2.1**), the factored moment of the section should be less than the moment capacity of the section under higher shear force, M_{dv}, calculated as given below:

a) Plastic or compact section:

$$M_{dv} = M_d - \beta(M_d - M_{fd}) \leq 1.2\, Z_e f_y / \gamma_{m0}$$

where

$\beta = (2\,V/V_d - 1)^2$;

M_d = plastic design moment of the whole section disregarding high shear force effect (*see* **15.2.1.2**); considering web buckling effects (*see* **15.2.1.1**);

V = factored applied shear force as governed by web yielding or web buckling;

V_d = design shear strength as governed by web yielding or web buckling (*see* **15.4.1** or **15.4.2**);

M_{fd} = plastic design strength of the area of the cross section excluding the shear area, considering partial safety factor γ_{m0}; and

Z_e = elastic section modulus of the whole section.

b) Semi-compact section:

$$M_{dv} = Z_e f_y / \gamma_{m0}$$

16.3 Combined Axial Force and Bending Moment

Under combined axial force and bending moment, section strength as governed by material failure and member strength as governed by buckling failure shall be checked in accordance with **16.3.1** and **16.3.2** respectively.

16.3.1 *Section Strength*

16.3.1.1 *Plastic and compact sections*

In the design of members subjected to combined axial force (tension or compression) and bending moment, the following should be satisfied:

$$\left(\frac{M_{\mathrm{y}}}{M_{\mathrm{ndy}}}\right)^{\alpha_1} + \left(\frac{M_{\mathrm{z}}}{M_{\mathrm{ndz}}}\right)^{\alpha_2} \leq 1.0$$

Conservatively, the following equation may also be used under combined axial force and bending moment:

$$\frac{N}{N_{\mathrm{d}}} + \frac{M_{\mathrm{y}}}{M_{\mathrm{dy}}} + \frac{M_{\mathrm{z}}}{M_{\mathrm{dz}}} \leq 1.0$$

where

α_1, α_2 = constants as given in Table 17;

A_{g} = gross area of the cross section;

M_{dy}, M_{dz} = design strength under corresponding moment acting alone (*see* **15.2**);

M_{ndy}, M_{ndz} = design reduced flexural strength under combined axial force and the respective uniaxial moment acting alone (*see* **16.3.1.2**);

M_{y}, M_{z} = factored applied moments about the minor and major axis of the cross section, respectively;

N = factored applied axial force (Tension, T or Compression, P);

N_{d} = design strength in tension, T_{d} as obtained from **12** or in compression due to yielding given by $N_{\mathrm{d}} = A_{\mathrm{g}} f_{\mathrm{y}}/\gamma_{\mathrm{m0}}$; and

γ_{m0} = partial factor of safety in yielding.

16.3.1.2 For plastic and compact sections without bolts holes, the following approximations may be used for evaluating M_{ndy} and M_{ndz}:

a) Plates:

$$M_{\mathrm{nd}} = M_{\mathrm{d}}\,(1 - n^2)$$

b) Welded I or H-sections:

$$M_{ndy} = M_{dy}\left[1 - \left(\frac{n-a}{1-a}\right)^2\right] \leq M_{dy} \qquad (n \geq a)$$

$$M_{\mathrm{ndz}} = M_{\mathrm{dz}}\,(1 - n)\,/\,(1 - 0.5a) \leq M_{\mathrm{dz}}$$

where

$n = N/N_{\mathrm{d}}$ and $a = (A - 2\,b\,t_{\mathrm{f}})\,/A \leq 0.5$

c) For standard I or H sections:

$M_{\mathrm{ndz}} = 1.11\,M_{\mathrm{dz}}\,(1 - n) \leq M_{\mathrm{dz}}$

for $n \leq 0.2$, $M_{\mathrm{ndy}} = M_{\mathrm{dy}}$

for $n > 0.2$, $M_{\mathrm{ndy}} = 1.56\,M_{\mathrm{dy}}\,(1 - n)\,(n + 0.6)$

d) For rectangular hollow sections and welded box sections:

When the section is symmetric about both axes and without bolt holes:

$$M_{\mathrm{ndy}} = M_{\mathrm{dy}}\,(1 - n)/(1 - 0.5a_{\mathrm{f}}) \leq M_{\mathrm{dy}}$$

$$M_{\mathrm{ndz}} = M_{\mathrm{dz}}\,(1 - n)/(1 - 0.5a_{\mathrm{w}}) \leq M_{\mathrm{dz}}$$

where

$a_{\mathrm{f}} = (A - 2\,h\,t_{\mathrm{w}})/A \leq 0.5$

$a_{\mathrm{w}} = (A - 2\,b\,t_{\mathrm{f}})/A \leq 0.5$

e) Circular hollow tubes without bolt holes:

$$M_{\mathrm{nd}} = 1.04\,M_{\mathrm{d}}\,(1 - n^{1.7}) \leq M_{\mathrm{d}}$$

Table 17 Constants α_1 and α_2

(*Clause* 16.3.1.1)

Sl No. (1)	Section (2)	α_1 (3)	α_2 (4)
i)	I and Channel	$5n \geq 1$	2
ii)	Circular tubes	2	2
iii)	Rectangular tubes	$1.66/(1 - 1.13n^2) \leq 6$	$1.66/(1 - 1.13n^2) \leq 6$
iv)	Solid rectangles	$1.73 + 1.8n^3$	$1.73 + 1.8\,n^3$

NOTE — $n = N/N_{\mathrm{d}}$

16.3.1.3 *Semi-compact section*

In the absence of high shear force (*see* **16.2.1**), semi-compact section design is satisfactory under combined axial force and bending, if the maximum longitudinal stress under combined axial force and bending, f_{x} satisfies the following criteria:

$$f_{\mathrm{x}} \leq f_{\mathrm{y}}/\gamma_{\mathrm{m0}}$$

For cross section without holes, the above criterion reduces to,

$$\frac{N}{N_{\mathrm{d}}} + \frac{M_{\mathrm{y}}}{M_{\mathrm{dy}}} + \frac{M_{\mathrm{z}}}{M_{\mathrm{dz}}} \leq 1.0$$

where

N_{d}, M_{dy}, M_{dz} are as defined in **16.3.1.1**.

16.3.2 *Overall Member Strength*

Members subjected to combined axial force and bending moment shall be checked for overall buckling failure as given in this section.

16.3.2.1 *Bending and axial tension*

The reduced effective moment, M_{eff}, under tension and bending calculated as given below, should not exceed the bending strength due to lateral torsional buckling, M_{d} (*see* **15.2.2**),

$$M_{\mathrm{eff}} = \left[M - \psi\,T\,Z_{\mathrm{ec}}/A\right] \leq M_{\mathrm{d}}$$

where

A = area of cross section;

M, T = factored applied moment and tension, respectively;

Z_{ec} = elastic section modulus of the section with respect to extreme compression fibre;

ψ = 0.8, if T and M can vary independently, or otherwise; and

= 1.0.

16.3.2.2 *Bending and axial compression*

Members subjected to combined axial compression and biaxial bending shall satisfy the following interaction relationships:

$$\frac{P}{P_{dy}} + K_{yy}\frac{M_y}{M_{dy}} + K_{yz}\frac{M_z}{M_{dz}} \leq 1.0$$

$$\frac{P}{P_{dz}} + K_{zy}\frac{M_y}{M_{dy}} + K_{zz}\frac{M_z}{M_{dz}} \leq 1.0$$

where

K_{yy}, k_{yz}, K_{zy}, K_{zz} = interaction factors as given in Table 18;

M_{dy}, M_{dz} = design bending strength about y (minor) or z (major) axis, considering laterally unsupported length of the cross section [*see* 15];

M_y, M_z = maximum factored applied bending moments about y and z-axis of the member, respectively;

P = applied axial compression under factored load; and

P_{dy}, P_{dz} = design strength under axial compression as governed by buckling about minor (y) and major (z) axis respectively.

17 CONNECTIONS

17.1 General

17.1.1 This Section deals with the design and detailing requirements for joints between members. Connection elements consist of components such as cleats, gusset plates, brackets, connecting plates and connectors such as rivets, bolts, pins, and welds. The connections in a structure shall be designed so as to be consistent with the assumptions made in the analysis of the structure and comply with the requirements specified in this section. Connections shall be capable of transmitting the calculated design actions.

17.1.2 Where members are connected to the surface of a web or the flange of a section, the ability of the web or the flange to transfer the applied forces locally should be checked and where necessary, local stiffening provided.

17.1.3 Ease of fabrication and erection should be considered in the design of connections. Attention should be paid to clearances necessary for field erection, tolerances, tightening of fasteners, welding procedures, subsequent inspection, surface treatment and maintenance.

17.1.4 The ductility of steel assists the distribution of forces generated within a joint. Effects of residual stresses and stresses due to tightening of fasteners and normal tolerances of fit-up need not therefore be considered in connection design, provided ductile behaviour is ensured.

17.1.5 In general, use of different forms of fasteners to transfer the same force shall be avoided. However, when different forms of fasteners are used to carry a shear load or when welding and fasteners are combined, then one form of fastener shall be normally designed to carry the total load. Nevertheless, fully tensioned friction grip bolts may be designed to share the load with welding, provided the bolts are fully tightened to develop necessary pretension after welding.

17.1.6 The partial safety factor in the evaluation of design strength of connections shall be taken as given in Table 5.

17.2 Location Details of Fasteners

17.2.1 *Clearances for Holes for Fasteners*

Bolts may be located in standard size, over size, short slotted or long slotted hole, as follows:

a) *Standard clearance hole* — Except where fitted bolts, bolts in low-clearance or oversize holes are specified, the diameter of standard clearance holes for fasteners shall be as given in Table 20;

b) *Oversize hole* — Holes of size larger than the standard clearance holes, as given in Table 20 may be used in slip resistant connections and hold down bolted connections, only where specified, provided the oversize;

c) Holes in the outer ply is covered by a cover plate of sufficiently large size and thickness and having a hole not larger than the standard clearance hole (and hardened washer in slip resistant connections); and

d) *Short and long slots* — Slotted holes of size larger than the standard clearance hole, as given in Table 20 may be used in slip resistant connections and hold down bolted connections, only where specified, provided the oversize holes in the outer ply is covered by a cover plate of sufficiently large size and thickness and having a hole of size not larger than the standard clearance hole (and hardened washer in slip resistant connection).

Table 20 Clearances for Fastener Holes

(*Clauses* 17.2.1 *and* 24.2.2.1)

Sl No.	**Nominal Size of Fastener, *d*** mm	**Size of the Hole = Nominal Diameter of the Fastener + Clearances** mm			
		Standard clearance in diameter and width of slot	Over size clearance in diameter	Clearance in the length of the slot	
				Short Slot	Long Slot
(1)	(2)	(3)	(4)	(5)	(6)
i)	12 to 14	1.0	3.0	4.0	2.5 *d*
ii)	16 to 22	2.0	4.0	6.0	2.5 *d*
iii)	24	2.0	6.0	8.0	2.5 *d*
iv)	Larger than 24	3.0	8.0	10.0	2.5 *d*

17.2.2 *Minimum Spacing*

The distance between centres of fasteners shall not be less than 2.5 times the nominal diameter of the fastener.

17.2.3 *Maximum Spacing*

17.2.3.1 The distance between the centres of any two adjacent fasteners shall not exceed 32*t* or 300 mm, whichever is less, where *t* is the thickness of the thinner plate.

17.2.3.2 The distance between the centres of two adjacent fasteners (pitch) in a line lying in the direction of stress, shall not exceed 16*t* or 200 mm, whichever is less, in tension members and 12*t* or 200 mm, whichever is less, in compression members; where *t* is the thickness of the thinner plate. In the case of compression members wherein forces are transferred through butting faces, this distance shall not exceed 4.5 times the diameter of the fasteners for a distance equal to 1.5 times the width of the member from the butting faces.

17.2.3.3 The distance between the centres of any two consecutive fasteners in a line adjacent and parallel to an edge of an outside plate shall not exceed 100 mm plus 4*t* or 200 mm, whichever is less, in compression and tension members; where *t* is the thickness of the thinner outside plate.

17.2.3.4 When fasteners are staggered at equal intervals and the gauge does not exceed 75 mm, the spacing specified in **17.2.3.2** and **17.2.3.3** between centres of fasteners may be increased by 50 percent, subject to the maximum spacing specified in **17.2.3.1**.

17.2.4 *Edge and End Distances*

17.2.4.1 The edge distance is the distance at right angles to the direction of stress from the centre of a hole to the adjacent edge. The end distance is the distance in the direction of stress from the centre of a hole to the end of the element.

In slotted holes, the edge and end distances should be measured from the edge or end of the material to the centre of its end radius or the centre line of the slot, whichever is smaller. In oversize holes, the edge and end distances should be taken as the distance from the relevant edge/end plus half the diameter of the standard clearance hole corresponding to the fastener, less the nominal diameter of the oversize hole.

17.2.4.2 The minimum edge and end distances from the centre of any hole to the nearest edge of a plate shall not be less than 1.7 times the hole diameter in case of sheared or hand-flame cut edges; and 1.5 times the hole diameter in case of rolled, machine-flame cut, sawn and planed edges.
